The presence of this chapter in the *USP* does not mean that chemical indicators and integrators are primary release requirements for parametric released product. The recorded and documented measurements from established thermometric measurement systems and associated process controllers (that have been calibrated and used during initial and periodic validation studies, as well as in routine production) can be considered to be primary, product-release systems for parametric release.

PERFORMANCE

Performance standards within lots and between lots of physicochemical indicators or integrators from a given manufacturer should be consistent. They should not interact physically or chemically with any container or product when placed adjacent to the product for sterilization in the sterilizer load, and should not alter the strength, quality, or purity of the sterilized article. The safety of personnel handling the physicochemical indicators or integrators should also be assessed, and, if need be, appropriate precautions should be taken.

Similar to biological indicators, chemical indicators are considered Class II devices and require the indicator manufacturer to obtain a device 510K approval prior to commercial use.

PHYSICOCHEMICAL INDICATORS

Recorded process engineering data can be supplemented by the presence in each sterilized batch of a physicochemical indicator. A physicochemical indicator is defined as a device that responds in a measurable fashion to one or more critical sterilization parameters.

A number of different kinds of indicators dependent on chemical or physicochemical means have been developed for monitoring sterilization cycles. Some products are used in a sterilization apparatus for monitoring whether the contents have been exposed to a selected factor (i.e., temperature) of the particular sterilization cycle, but may not show the duration or intensity of such exposure. Chemical and physicochemical indicators are used to monitor a physical parameter of a sterilization apparatus and can be placed on the outside of the packages of articles to be sterilized, or they may be distributed within the sterilizer load. In the latter case, one can evaluate to some extent the effect of the packaging material and configuration of the load on the selected parameter.

PHYSICOCHEMICAL INTEGRATORS

A physicochemical integrator is defined as a device that responds to a sterilization process critical parameter, which results in a measurable or quantifiable value that can be correlated to some standard of microbial lethality. Physicochemical integrators have been designed to broadly match the predictable inactivation of those spore preparations in biological indicators that have high and defined resistance to the sterilizing agent.

The manufacturers of physicochemical integrators should provide data to demonstrate that the labeled performance characteristics tests of the integrators are met. Users of physicochemical integrators should verify that specific measured values directly correlate to successful microbial lethality in a validated sterilization cycle.

A physicochemical integrator indicates whether or not the critical combination of physical parameters of a validated sterilization cycle has been met or exceeded. The integrator is not generally used as a substitute for a biological indicator in the development and validation of sterilization cycles. An indication by a physicochemical integrator that the critical combination of physical parameters of a stated sterilization cycle has been achieved should not be considered equivalent to the inactivation of spores of a variety of biological indicators. However, the physicochemical integrator can detect whether the sterilization process has been continued for too long, at too high a temperature or gas concentration, or has been overexposed to radiation.

The interval between the lower range and the upper range of time, or any other designated set of parameters, resembles the survival time and kill time window characteristics of a biological indicator. This interval should not be wider than that desirable for the designated parameter, but may be narrower if the manufacturer is able to achieve consistent performance over a narrower range. Even where a sterilization apparatus with consistent performance is used, cases may occur where the determined performance characteristics of the integrator differ from the label claims. This could represent a difference between the user's apparatus performance and the manufacturer's apparatus used for verifying the label claims. Closer conformity to the label claims may also be shown with any highly developed apparatus, such as a BIER vessel.^{1,2} Hence, the integrator requires its own precautions in use and has appropriate interpretive criteria within its performance characteristics. Tests for performance characteristics of physicochemical integrators include determination under applicable defined conditions of (a) the maximum time of exposure at which none of the specimens indicates that adequate exposure to the cycle has occurred, and (b) a minimum time of exposure at which all specimens show that adequate exposure to the cycle has occurred. An intermediate time of exposure, where about half the number of specimens show adequate exposure, could indicate

¹ Standard for BIER/Steam Vessels, 27 March 1981, Association for the Advancement of Medical Instrumentation (AAMI), 3330 Washington Boulevard, Suite 400, Arlington, VA 22201-4598.

² Standard for BIER/EO Vessels, 27 March 1992, Association for the Advancement of Medical Instrumentation (AAMI), 3330 Washington Boulevard, Suite 400, Arlington, VA 22201-4598.

an approaching exposure endpoint for the physicochemical integrator.

Because an indicator reflects only the interaction of the physical parameters of sterilization, it will not be affected by some of the factors that may influence the resistance of the microbial load on the products to be sterilized (e.g., progeny resistance, spore population, inoculum substrate, oil, salts, proteins, or residues or configurations), all of which may protect a contaminated area from penetration by the sterilizing agent. (Hence, the inappropriateness of these devices for cycle development.) There are other factors, however, that may affect a biological indicator that could also affect a physicochemical integrator (e.g., interfering configuration of a pack in which the integrator was placed, variations in the applied timing or temperature control, or failure of the apparatus to reach the set temperature or meet other requirements).

Defective performance of the sterilization apparatus generally can be ascertained from gauges and from records of temperature, pressure, time of exposure, and gas concentration, whichever are applicable. The integrator can only indicate inadequate, adequate, or excessive exposure to a combination of critical sterilization parameters. Where an integrator shows inadequate exposure to the sterilization parameters, it is necessary to ascertain whether the gauges and recordings reflect accurately the sterilization conditions within the sterilization chamber. Variations between sterilization vessels, which might affect the efficiency of a selected sterilization cycle, might be detectable by parallel exposure of several integrators in a number of locations in each sterilizer load.

Physicochemical integrators for steam sterilization are designed to react predictably to a particular combination of physical sterilization parameters: temperature, steam pressure, and time of exposure. Deviation to some extent of one or more of these critical parameters, not compensated by modification of other parameters, causes the integrator to indicate failure to reach the preset integrated limits.

Physicochemical integrators for ethylene oxide sterilization are designed with similar general principles as the integrators for steam sterilization, but to react predictably to the particular combination of the physical sterilization parameters: humidity, temperature, sterilizing gas concentration, and time of exposure. Deviation to some extent of one or more of these critical parameters, not compensated by modification of other parameters, causes the integrator to indicate failure to reach the preset integrated limits.

Physicochemical integrators have been designed to match broadly the predictable inactivation of spore preparations that have a high and defined resistance to the sterilizing agent. For steam sterilization, a strain of *Bacillus stearothermophilus* is used (see *Biological Indicator for Steam Sterilization, Paper Carrier*), and for ethylene oxide sterilization, a strain of *Bacillus subtilis*, subspecies *niger*, is used (see *Biological Indicator for Ethylene Oxide Sterilization, Paper Carrier*). Since there are no standard preparations of these strains, the performance characteristics of these physicochemical integrators must be interpreted in relation to a specific validated sterilization cycle.

Performance standards within lots and between lots of physicochemical integrators from a given manufacturer should be consistent. The integrators should not interact physically or chemically with container or product when placed adjacent to the product for sterilization in the sterilizer load, and shall not alter the strength, quality, or purity of the sterilized article beyond official requirements. Users should obtain information from integrator manufacturers on whether or not sterilization in the presence of physicochemical integrators may affect particular articles to be sterilized. In addition, safety in using these integrators should be verified.

Moist Heat Sterilization

The use of steam sterilization physicochemical integrators to supplement the information obtained through physical assessment of the critical operating parameters should be part of parametric release of moist heat sterilized products. These should be designed to enable the assurance that the lethality delivery specified for the process has been met or exceeded. The consistency of the performance of physicochemical integrators for moist heat sterilization should be ensured through the testing of performance characteristics that include testing of the performance of the indicator or integrator system at various pre-set selected moist heat process conditions.

Critical elements of this type of physicochemical integrator would include an organic compound sensitive to the combination of temperature and steam, a polymeric material penetrable by saturated steam, and a wicking device under the polymeric material that is in contact with the organic compound. As steam passes through the polymeric material, the organic compound melts in a predictable fashion in steps dependent on the steam temperature during the cycle. The liquefied material travels along the wick for a distance that can be measured on a scale. This organic compound has a stated melting temperature range. Some integrators may, for example, have melting ranges of 132.2° to 134.5° or of 137.0° to 142.0°. Other melting ranges could also be specified so as to indicate the sterilization parameters to which it has actually been exposed. The combination of the sterilization parameters, applied for the exposure time required for a stated moist heat sterilization cycle, is indicated on the front of the article by the linear travel of the melt.

These types of physicochemical integrators can also be used for so-called "flash" moist heat sterilization cycles in which the successive steps of the sterilization process are rapidly carried out in such a manner as to achieve the required lethality for the validated process. Other types of physicochemical integrators for moist heat sterilization can be used if they are also calibrated against a specified validated moist heat sterilization cycle.

Ethylene Oxide Sterilization

Physicochemical integrators for ethylene oxide sterilization should be designed to match broadly the predictable inactivation of spore preparations that have a high and defined resistance to ethylene oxide sterilization. The inactivation of spores of a strain of *Bacillus subtilis*, subspecies *niger*, can be used as a model, although other spores of relevant microorganisms can also be used. The critical elements of physicochemical integrators for ethylene oxide sterilization are a base with an organic compound along a linear indicator strip sensitive to a combination of temperature, humidity, and sterilizing gas concentration. Where the organic compound is exposed to a sterilizing gas mixture at a specific temperature and humidity, a chemical reaction triggers the appearance of a color along the linear indicator bar. This is dependent on the time of exposure under the conditions of ethylene oxide sterilization in a predictable fashion. The absence of fading or of decolorization of the indicator bar for a stated period after the sterilization cycle has been completed would confirm adequate humidification in the cycle. The integrator should be capable of detecting deviations from the prescribed parameters of temperature, sterilizing gas concentration, humidity, and time of exposure that may affect sterilization. It does not show the required reactions if exposed to reduced amounts of gas concentration, temperature, and humidity, even if exposed for prolonged periods.

Other types of physicochemical integrators for ethylene oxide sterilization based on different principles or mechanisms of integration of critical parameters of sterilization

could be used if they are also calibrated against a specified validated ethylene oxide sterilization cycle.

The consistency of performance of physicochemical integrators for ethylene oxide sterilization has to be ensured through the testing of performance characteristics at various pre-set selected times for a given ethylene oxide sterilization cycle.

(1211) STERILIZATION AND STERILITY ASSURANCE OF COMPENDIAL ARTICLES

This informational chapter provides a general description of the concepts and principles involved in the quality control of articles that must be sterile. Any modifications of or variations in sterility test procedures from those described under *Sterility Tests* (71) should be validated in the context of the entire sterility assurance program and are not intended to be methods alternative to those described in that chapter.

Within the strictest definition of sterility, a specimen would be deemed sterile only when there is complete absence of viable microorganisms from it. However, this absolute definition cannot currently be applied to an entire lot of finished compendial articles because of limitations in testing. The sterility of a lot purported to be sterile is therefore defined in probabilistic terms, where the likelihood of a contaminated unit or article is acceptably remote. Such a state of sterility assurance can be established only through the use of validated sterilization processes or aseptic processing, if any, under appropriate current good manufacturing practice, and not by reliance solely on sterility testing. The basic principles for validation and certification of a sterilizing process are enumerated as follows:

1. Establish that the process equipment has the capability of operating within the required parameters.
2. Demonstrate that the critical control equipment and instrumentation are capable of operating within the prescribed parameters for the process equipment.
3. Perform replicate cycles representing the required operational range of the equipment and employing actual or simulated product. Demonstrate that the processes have been carried out within the prescribed protocol limits and, finally, that the probability of microbial survival in the replicate processes completed is not greater than the prescribed limits.
4. Monitor the validated process during routine operation. Periodically as needed, requalify and recertify the equipment.
5. Complete the protocols, and document steps (1) through (4) above.

The principles and implementation of a program to validate an aseptic processing procedure are substantially more extensive than the validation of a sterilization process. In aseptic processing, the components of the final dosage form are sterilized separately and the finished article is assembled in an aseptic manner.

Proper validation of the sterilization process or the aseptic process requires a high level of knowledge of the field of sterilization and clean room technology. In order to comply with currently acceptable and achievable limits in sterilization parameters, it is necessary to employ appropriate instrumentation and equipment to control the critical parameters such as temperature, time, pressure, humidity, sterilizing gas concentration, and/or absorbed radiation. An important aspect of the validation program in many sterili-

zation procedures involves the employment of biological indicators (see *Biological Indicators* (1035)). The validated and certified process should be revalidated periodically; however, the revalidation program need not necessarily be as extensive as the original program.

A typical validation program, as outlined below, is one designed for the steam autoclave, but several of these principles may be applicable to the other sterilization procedures discussed in this informational chapter. The program comprises several stages.

The *installation qualification* stage is intended to establish that controls and other instrumentation are properly designed and calibrated. Documentation should be on file demonstrating the quality of the required utilities such as steam, water, and air. The *operational qualification* stage is intended to confirm that the empty chamber functions within the parameters of temperature at key chamber locations prescribed in the protocol. It is usually appropriate to develop heat profile records, i.e., simultaneous temperatures in the chamber employing multiple temperature-sensing devices. A typical acceptable range of temperature in the empty chamber is $\pm 1^\circ$ when the chamber temperature is not less than 121° . The *confirmatory* stage of the validation program is the actual sterilization of materials or articles. This determination requires the employment of temperature-sensing devices inserted into samples of the articles, as well as samples of the articles to which appropriate concentrations of suitable test microorganisms (biological indicators) have been added in operationally fully loaded autoclave configurations. The effectiveness of moist heat penetration into the actual articles and the time of the exposure are the two main factors that determine the lethality of the sterilization process. The *final* stage of the validation program requires the documentation of the supporting data developed in executing the program.

It is generally accepted that terminally sterilized injectable articles or critical devices purporting to be sterile, when sterilized, attain a 10^{-6} microbial survivor probability, i.e., assurance of less than or equal to 1 chance in 1 million that viable microorganisms are present in the sterilized article or dosage form. With heat-stable articles, the approach often is to exceed the critical time necessary to achieve the 10^{-6} microbial survivor probability (overkill) of presterilization bioburden that is considerably greater in population (typically 10^6) and resistance (typically D_{121} is equal to or greater than 1.0 minute) than the natural presterilization bioburden. However, with an article where extensive heat exposure may have a damaging effect, it will not be feasible to employ an overkill approach. In this latter instance, the development of the sterilization cycle depends heavily on knowledge of the population and resistance microbial burden of the product, based on examination, over a suitable time period, of a substantial number of lots of the presterilized product.

The D value is the time (in minutes) required to reduce the microbial population by 90% or 1 log cycle (i.e., to a surviving fraction of 1/10), at a specific lethal condition, such as, temperature. Therefore, where the D value of a BI preparation of, for example, *Geobacillus stearothermophilus* spores is 1.5 minutes under the process conditions defined, e.g., at 121° , if it is treated for 12 minutes under the same conditions, it can be stated that the lethality input is 8D. The effect of applying this input to the product would depend on the initial microbial burden. Assuming that its resistance to sterilization is equivalent to that of the BI, if the microbial burden of the product in question is 10^2 microorganisms, a lethality input of 2D yields a microbial burden of 1 (10^0 theoretical), and a further 6D yields a calculated microbial survivor probability of 10^{-6} . (Under the same conditions, a lethality input of 12D may be used in a typical "overkill" approach.) Generally, the survivor probability achieved for the article under the validated sterilization cycle is not completely correlated with what may occur with the BI. For valid use, therefore, it is essential that the resistance of the BI be greater than that of the natural microbial burden of the article sterilized. It is then appropriate to make a

worst-case assumption and treat the microbial burden as though its heat resistance were equivalent to that of the BI, although it is not likely that the most resistant of a typical microbial burden isolates will demonstrate a heat resistance of the magnitude shown by this species, frequently employed as a BI for steam sterilization. In the above example, a 12-minute cycle is considered adequate for sterilization if the product had a microbial burden of 10^2 microorganisms. However, if the indicator originally had 10^6 microorganisms content, actually a 10^{-2} probability of survival could be expected; i.e., 1 in 100 BIs may yield positive results. This type of situation may be avoided by selection of the appropriate BI. Alternatively, high content indicators may be used on the basis of a predetermined acceptable count reduction.

The D value for the *Geo bacillus stearothermophilus* preparation determined or verified for these conditions should be reestablished when a specific program of validation is changed. Determination of survival curves (see *Biological Indicators* (1035)), or what has been called the fractional cycle approach, may be employed to determine the D value of the biological indicator preferred for the specific sterilization procedure. The fractional cycle approach may also be used to evaluate the resistance of the microbial burden. Fractional cycles are studied either for microbial count-reduction or for fraction negative achievement. These numbers may be used to determine the lethality of the process under production conditions. The data can be used in qualified production equipment to establish appropriate sterilization cycles. A suitable biological indicator such as the *Geo bacillus stearothermophilus* preparation may be employed also during routine sterilization. Any microbial burden-based sterilization process requires adequate surveillance of the microbial resistance of the article to detect any changes, in addition to periodic surveillance of other attributes.

METHODS OF STERILIZATION

In this informational chapter, five methods of terminal sterilization, including removal of microorganisms by filtration and guidelines for aseptic processing, are described. Modern technological developments, however, have led to the use of additional procedures. These include blow-molding (at high temperatures), forms of moist heat other than saturated steam and UV irradiation, as well as on-line continuous filling in aseptic processing. The choice of the appropriate process for a given dosage form or component requires a high level of knowledge of sterilization techniques and information concerning any effects of the process on the material being sterilized.¹

¹Documents addressing the development and validation of sterilization cycles and related topics include, by the Parenteral Drug Association, Inc. (PDA), *Validation of Moist Heat Sterilization Processes: Cycle Design, Development, Qualification and Ongoing Control* (Technical Report No. 1); *Process Simulation for Aseptically Filled Products* (Technical Report No. 22); *Sterilizing Filtration of Liquids* (Technical Report No. 26); and *Validation of Dry Heat Processes Used for Sterilization and Depyrogenation* (Technical Monograph No. 3); and by the Pharmaceutical Manufacturers Association (PMA), *Validation of Sterilization of Large-Volume Parenterals—Current Concepts* (Science and Technology Publication No. 25). Other technical publications include Health Industry Manufacturers Association (HIMA), *Validation of Sterilization Systems* (Report No. 78-4.1); *Sterilization Cycle Development* (Report No. 78-4.2); *Industrial Sterility: Medical Device Standards and Guidelines* (Document #9, Vol. 1); and *Operator Training . . . for Ethylene Oxide Sterilization, for Steam Sterilization Equipment, for Dry Heat Sterilization Equipment, and for Radiation Sterilization Equipment* (Report Nos. 78-4.5 through 4.8). Recommended practice guidelines published by the Association for the Advancement of Medical Instrumentation (AAMI) include *Guideline for Industrial Ethylene Oxide Sterilization of Medical Devices—Process Design, Validation, Routine Sterilization* (No. OPEO-12/81) and *Process Control Guidelines for the Radiation Sterilization of Medical Devices* (No. RS-P 10/82). Additional radiation sterilization content can be found in ISO 11137—*Sterilization of Health Care Products—Requirements for Validation and Routine Control—Radiation Sterilization*. These more detailed publications should be consulted for more extensive treatment of the principles and procedures described in this chapter.

Steam Sterilization

The process of thermal sterilization employing saturated steam under pressure is carried out in a chamber called an autoclave. It is probably the most widely employed sterilization process. The basic principle of operation is that the air in the sterilizing chamber is displaced by the saturated steam, achieved by employing vents or traps. In order to displace air more effectively from the chamber and from within articles, the sterilization cycle may include air and steam evacuation stages. The design or choice of a cycle for given products or components depends on a number of factors, including the heat lability of the material, knowledge of heat penetration into the articles, and other factors described under the validation program (see above). Apart from that description of sterilization cycle parameters, using a temperature of 121°, the F_0 concept may be appropriate. The F_0 , at a particular temperature other than 121°, is the time (in minutes) required to provide the lethality equivalent to that provided at 121° for a stated time. Modern autoclaves generally operate with a control system that is significantly more responsive than the steam reduction valve of older units that have been in service for many years. In order for these older units to achieve the precision and level of control of the cycle discussed in this chapter, it may be necessary to upgrade or modify the control equipment and instrumentation on these units. This modification is warranted only if the chamber and steam jacket are intact for continued safe use and if deposits that interfere with heat distribution can be removed.

Dry-Heat Sterilization/Depyrogenation

The process of thermal sterilization of Pharmacopeial articles by dry heat may be carried out by a batch process in an oven designed expressly for that purpose or in a dry-heat tunnel in which glass containers move on a continuous basis through the system. A dry-heat sterilization/depyrogenation system is supplied with heated, HEPA filtered air, distributed uniformly throughout the unit by convection or radiation and employing a blower system with devices for sensing, monitoring, and controlling all critical parameters. A typical acceptable range in temperature in the empty chamber is $\pm 15^\circ$ when the unit is operating at not less than 250°.

In addition to the batch process described above, the continuous-tunnel system usually requires a much higher temperature than cited above for the batch process because of a much shorter dwell time. The continuous process also usually necessitates a rapid cooling stage prior to the aseptic filling operation. In the qualification and validation program, in view of the short dwell time, parameters for uniformity of the temperature, and particularly the dwell time, should be established.

Because depyrogenation is a more rigorous challenge for dry-heat processing systems than biological indicator inactivation, it is generally not necessary to include BIs when validating dry-heat processes if validation of depyrogenation is demonstrated. A 3 log cycle reduction or greater is a suitable acceptance criterion for depyrogenation and when successfully demonstrated will ensure not only adequate depyrogenation of compendial articles but also sterilization. Depyrogenation tests are typically done using articles inoculated with reference standard endotoxin. Articles are then evaluated after exposure for residual levels of endotoxin using *Limulus* lysate-based assays. For additional information on the endotoxin assay, see *Bacterial Endotoxins Test* (85).

Gas Sterilization

The choice of gas sterilization as an alternative to heat is frequently made when the material to be sterilized cannot withstand the high temperatures obtained in the steam ster-

ilization or dry-heat sterilization processes. The most commonly employed method of gaseous sterilization is ethylene oxide. Among the disadvantages of ethylene oxide are its highly flammable nature unless mixed with suitable inert gases, its mutagenic properties, and the possibility of toxic residues in treated materials, particularly those containing chloride ions. The sterilization process is generally carried out in a pressure and vacuum-rated chamber designed similarly to a steam autoclave but with the additional features (see below) unique to sterilizers employing this gas. Facilities employing this sterilizing agent should be designed to provide adequate post sterilization degassing, to enable microbial survivor monitoring, and to minimize exposure of operators to the potentially harmful gas.²

Validation of a sterilizing process employing ethylene oxide gas is accomplished along the lines discussed earlier. However, the program is more comprehensive than for the other sterilization procedures, because in addition to temperature, the humidity, vacuum/positive pressure, and ethylene oxide concentration also require appropriate parametric control. An important determination is to demonstrate that all critical process parameters in the chamber are adequate during the entire cycle. Because the sterilization parameters applied to the articles to be sterilized are critical variables, it is frequently advisable to precondition the load to achieve the required moisture content in order to minimize the time of holding at the required temperature before placement of the load in the ethylene oxide chamber. Validation is generally conducted employing product inoculated with appropriate BIs such as spore preparations of *Bacillus atrophaeus*. For validation they may be used in full chamber loads of product, or simulated product. The monitoring of moisture and gas concentration requires the utilization of sophisticated instrumentation that only knowledgeable and experienced individuals can calibrate, operate, and maintain. BIs may also be employed in monitoring routine runs.

As is indicated elsewhere in this chapter, the BI may be employed in a fraction negative mode to establish the ultimate microbiological survivor probability in designing an ethylene oxide sterilization cycle using inoculated product or inoculated simulated product.

One of the principal limiting factors of the ethylene oxide sterilization process is the limited ability of the gas to diffuse to the innermost product areas that require sterilization. Package design and chamber loading patterns therefore must be determined to allow for necessary gas penetration. The reader is referred to ISO 11135 for a complete description of process development, validation, and routine control of ethylene oxide sterilization processes.

Sterilization by Ionizing Radiation

The rapid proliferation of medical devices unable to withstand heat sterilization and the concerns about the safety of ethylene oxide have resulted in increasing applications of radiation sterilization. This method may also be applicable to active pharmaceutical ingredients and final dosage forms. The advantages of sterilization by irradiation include low chemical reactivity, low measurable residues, and the fact that there are fewer variables to control. In fact, radiation sterilization is unique in that the basis of control is essentially that of the absorbed radiation dose, which can be precisely measured. Dose-setting and dose-substantiation procedures are typically used to validate the radiation dose required to achieve a sterility assurance level. Irradiation causes only a minimal temperature rise but can affect certain grades and types of plastics and glass.

² See *Ethylene Oxide*, Encyclopedia of Industrial Chemical Analysis, 1971, 12, 317–340, John Wiley & Sons, Inc., and *Use of Ethylene Oxide as a Sterilant in Medical Facilities*, NIOSH Special Occupational Hazard Review with Control Recommendations, August 1977, U.S. Department of Health and Human Services, Public Health Service, Centers for Disease Control and Prevention, National Institute for Occupational Safety and Health, Division of Criteria Documentation and Standards Development, Priorities and Research Analysis Branch, Rockville, MD.

The two types of ionizing radiation in use are radioisotope decay (gamma radiation) and electron-beam radiation. In either case the radiation dose established to yield the required degree of sterility assurance should be such that, within the range of minimum and maximum doses set, the properties of the article being sterilized are acceptable. The reader is referred to ISO 11137-1, -2, and -3 for a complete description of process development, validation, and routine control of ionizing radiation processes.

Sterilization by Filtration

The sterilization of fluids by filtration is a separative process and differs from the other methods of sterilization that rely on destructive mechanisms. Filtration through microbial retentive materials is frequently employed for the sterilization of heat-labile solutions by physical removal of the contained microorganisms. A filter assembly generally consists of a porous matrix integrated with or clamped into a housing. The effectiveness of a filter medium depends upon the pore size of the porous material, the prefiltration bioburden, and may depend upon adsorption of bacteria on or in the filter matrix or upon a sieving mechanism. There is some evidence to indicate that sieving is the more important component of the mechanism. While fiber-shedding filters are to be avoided unless no alternative filtration procedures are possible, it should be noted that in accordance with 21CFR 211.72, the use of asbestos-containing filters is prohibited. Where a fiber-shedding filter is required, it is obligatory that the process include a nonfiber-shedding filter introduced downstream or subsequent to the initial filtration step.

Filter Rating—The pore sizes of filter membranes are rated by a nominal rating that reflects the capability of the filter membrane to retain microorganisms of size represented by specified strains, not by determination of an average pore size and statement of distribution of sizes. Sterilizing filters cannot be narrowly defined because, depending upon the bioburden present in the fluid stream, different filters may be considered effective for sterilization. Currently a sterilizing filter can be defined as, “a filter that, when appropriately validated, will remove all microorganisms from a fluid stream, producing a sterile effluent”. The nominal ratings of sterilizing filters based on microbial retention properties differ when rating is done by other means, e.g., by retention of latex spheres of various diameters. It is the user’s responsibility to select a filter of correct rating for the particular purpose, depending on the nature of the product (especially considering its potential bioburden) to be filtered. It is not feasible to repeat the tests of filtration capacity in the user’s establishment. Microbial challenge tests are preferably performed under a manufacturer’s conditions on each lot of manufactured filter membranes.

The user must determine whether filtration parameters employed in manufacturing will significantly influence microbial retention efficiency. Some of the other important concerns in the validation of the filtration process include product compatibility, sorption of drug, preservative or other additives, and initial effluent endotoxin content.

Because the effectiveness of the filtration process is also influenced by the microbial burden of the solution to be filtered, determining the microbiological quality of solutions prior to filtration is an important aspect of the validation of the filtration process, in addition to establishing the other parameters of the filtration procedure, such as pressures, flow rates, and filter unit characteristics. Hence, another method of describing filter-retaining capability is the use of the log reduction value (LRV). For instance, a 0.2- μ m filter that can retain 10^7 microorganisms of a specified strain will have an LRV of not less than 7 under the stated conditions.

The housings and filter assemblies that are chosen should first be validated for compatibility and integrity by the user. While it may be possible to mix assemblies and filter membranes produced by different manufacturers, the compatibil-

ity of these hybrid assemblies should first be validated. Additionally, there are other tests to be made by the manufacturer of the membrane filter, which are not usually repeated by the user. These include microbiological challenge tests. Results of these tests on each lot of manufactured filter membranes should be obtained from the manufacturer by users for their records.

Filtration for sterilization purposes is usually carried out with assemblies having membranes of nominal pore size rating of 0.2 μm or less. A membrane filter assembly must be tested for initial integrity prior to use, provided that such test does not impair the safety, integrity, and validity of the system, and should be tested after the filtration process is completed to demonstrate that the filter assembly maintained its integrity throughout the entire filtration procedure. Typical use tests are the bubble point test, the diffusive airflow test, the pressure hold test, and the forward flow test. These tests should be correlated with microorganism retention.

Unidirectional Aseptic Processing

Although there is general agreement that sterilization of the final filled container as a dosage form or final packaged device is the preferred process for ensuring the minimal risk of microbial contamination in a lot, there is a substantial class of products that are not terminally sterilized but are prepared by a series of aseptic steps. These are designed to prevent the introduction of viable microorganisms into components, where sterile, or once an intermediate process has rendered the bulk product or its components free from viable microorganisms. The fundamental difference between aseptically produced sterile products and terminally sterilized products is the presence of a step that can be validated, whereby the final package is subjected to conditions shown to kill viable contaminants. Consequently, an aseptically filled product labeled as sterile must use a system of risk assessments to establish that an acceptable level of sterility assurance has been achieved. Current technology cannot provide an adequate safety assessment based on individual unit testing. In currently used methods of environmental monitoring, process simulations have not been shown to correlate directly with contaminated finished products. Finished product destructive testing (sterility tests) can only examine a very small percentage of a lot and are thus only capable of detecting grossly contaminated lots. This section provides a review of the principles involved in producing aseptically processed products with a minimal risk of microbial contamination in the finished lot of final dosage forms.

A product defined as aseptically processed is likely to consist of components that have been sterilized by one of the processes described earlier in this chapter. For example, the bulk product, if a filterable liquid, may have been sterilized by filtration. The final empty container components would probably be sterilized by heat, dry heat being employed for glass vials and an autoclave being employed for rubber closures. The areas of critical concern are the immediate microbial environment where these presterilized components are exposed during assembly to produce the finished dosage form and the aseptic filling operation.

The requirements for a properly designed, validated, and maintained filling or other aseptic processing facility are mainly directed to (1) an air environment that is suitably controlled with respect to viable and nonviable particulates, of a proper design to permit effective maintenance of air supply units, and (2) the provision of trained operating personnel who are adequately equipped and gowned. The desired environment may be achieved through the high level of air filtration technology now available, which contributes to the delivery of air of the requisite microbiological qual-

ity.³ The facilities include both primary (in the vicinity of the exposed article) and secondary (where the aseptic processing is carried out) barrier systems.

For a properly designed aseptic processing facility or aseptic filling area, consideration should be given to such features as nonporous and smooth surfaces, including walls and ceilings that can withstand routine decontamination; gowning rooms with adequate space for personnel and storage of sterile garments; adequate separation of preparatory rooms for personnel from final aseptic processing rooms, with the availability, if necessary, of devices such as airlocks and air showers; proper pressure differentials between rooms, the most positive pressure being in the aseptic processing rooms or areas; the employment of unidirectional airflow in the immediate vicinity of exposed product or components, and filtered air exposure thereto, with adequate air change frequency; appropriate humidity and temperature environmental controls; and a documented sanitization program. Proper training of personnel in hygienic and gowning techniques should be undertaken so that, for example, gowns, gloves, and other body coverings substantially cover exposed skin surfaces.

Certification and validation of the aseptic process and facility are achieved by establishing the efficiency of the filtration systems, by employing microbiological environmental monitoring procedures, and by processing of sterile culture medium as simulated product.

Monitoring of the aseptic facility should include periodic HEPA filter evaluation and testing, as well as routine particulate and microbiological environmental monitoring. Periodic media-fill or process-simulation testing should also be performed.

STERILITY TESTING OF LOTS

It should be recognized that the referee sterility test might not detect microbial contamination if present in only a small percentage of the finished articles in the lot because the specified number of units to be taken imposes a significant statistical limitation on the utility of the test results. This inherent limitation, however, has to be accepted, because current knowledge offers no nondestructive alternatives for ascertaining the microbiological quality of every finished article in the lot, and it is not a feasible option to increase the number of specimens significantly. For information regarding the conduct of the sterility test please see *Sterility Tests* (71).

(1216) TABLET FRIABILITY

This general information chapter has been harmonized with the corresponding texts of the *European Pharmacopoeia* and the *Japanese Pharmacopoeia*. The harmonized texts of these three pharmacopoeias are therefore interchangeable, and the methods of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia* may be used for demonstration of compliance instead of the present *United States Pharmacopoeia* general information chapter method. These pharmacopoeias have undertaken not to make any unilateral change to this harmonized chapter.

This chapter provides guidelines for the friability determination of compressed, uncoated tablets. The test procedure

³ Available published standards for such controlled work areas include the following: (1) ISO 14644 1-7 Cleanrooms and Associated Controlled Environments. (2) NASA Standard for Clean Room and Work Stations for Microbially Controlled Environment, publication NHB5340.2, Aug. 1967. (3) Contamination Control of Aerospace Facilities, U.S. Air Force, T.O. 00-25-203, 1 Dec. 1972, change 1-1, Oct. 1974.

presented in this chapter is generally applicable to most compressed tablets. Measurement of tablet friability supplements other physical strength measurements, such as tablet breaking force.

Use a drum,* with an internal diameter between 283 and 291 mm and a depth between 36 and 40 mm, of transparent synthetic polymer with polished internal surfaces, and subject to minimum static build-up (see figure for a typical apparatus). One side of the drum is removable. The tablets are tumbled at each turn of the drum by a curved projection with an inside radius between 75.5 and 85.5 mm that extends from the middle of the drum to the outer wall. The outer diameter of the central ring is between 24.5 and 25.5 mm. The drum is attached to the horizontal axis of a device that rotates at 25 ± 1 rpm. Thus, at each turn the tablets roll or slide and fall onto the drum wall or onto each other.

Tablet Friability Apparatus

For tablets with a unit weight equal to or less than 650 mg, take a sample of whole tablets corresponding as near as possible to 6.5 g. For tablets with a unit weight of more than 650 mg, take a sample of 10 whole tablets. The tablets should be carefully dedusted prior to testing. Accurately weigh the tablet sample, and place the tablets in the drum. Rotate the drum 100 times, and remove the tablets. Remove any loose dust from the tablets as before, and accurately weigh.

Generally, the test is run once. If obviously cracked, cleaved, or broken tablets are present in the tablet sample after tumbling, the sample fails the test. If the results are difficult to interpret or if the weight loss is greater than the targeted value, the test should be repeated twice and the mean of the three tests determined. A maximum mean weight loss from the three samples of not more than 1.0% is considered acceptable for most products.

If tablet size or shape causes irregular tumbling, adjust the drum base so that the base forms an angle of about 10° with the horizontal and the tablets no longer bind together when lying next to each other, which prevents them from falling freely.

Effervescent tablets and chewable tablets may have different specifications as far as friability is concerned. In the case of hygroscopic tablets, an appropriate humidity-controlled environment is required for testing.

* The apparatus meeting these specifications is available from laboratory supply houses such as VanKel Technology Group, 13000 Weston Parkway, Cary, NC 27513, or from Erweka Instruments, Inc., 56 Quirk Road, Milford, CT 06460.

Drums with dual scooping projections, or an apparatus with more than one drum, for the running of multiple samples at one time, are also permitted.

(1217) TABLET BREAKING FORCE

INTRODUCTION

There are a variety of presentations for tablets as delivery systems for pharmaceutical agents, such as rapidly disintegrating, slowly disintegrating, eroding, chewable, and lozenge. Each of these presentations places a certain demand on the bonding, structure, and integrity of the compressed matrix. Tablets must be able to withstand the rigors of handling and transportation experienced in the manufacturing plant, in the drug distribution system, and in the field at the hands of the end users (patients/consumers). Manufacturing processes such as coating, packaging, and printing can involve considerable stresses, which the tablets must be able to withstand. For these reasons, the mechanical strength of tablets is of considerable importance and is routinely measured. Tablet strength serves both as a criterion by which to guide product development and as a quality control specification.

One commonly employed test of the ability of tablets to withstand mechanical stresses determines their resistance to chipping and surface abrasion by tumbling them in a rotating cylinder. The percentage weight loss after tumbling is referred to as the *friability* of the tablets. Standardized methods and equipment for testing friability have been provided in general chapter *Tablet Friability* (1216).

Another measure of the mechanical integrity of tablets is their *breaking force*, which is the force required to cause them to fail (i.e., break) in a specific plane. The tablets are generally placed between two platens, one of which moves to apply sufficient force to the tablet to cause fracture. For conventional, round (circular cross-section) tablets, loading occurs across their diameter (sometimes referred to as diametral loading), and fracture occurs in that plane.

The breaking force of tablets is commonly called *hardness* in the pharmaceutical literature; however, the use of this term is misleading. In material science, the term *hardness* refers to the resistance of a surface to penetration or indentation by a small probe. The term *crushing strength* is also frequently used to describe the resistance of tablets to the application of a compressive load. Although this term describes the true nature of the test more accurately than does *hardness*, it implies that tablets are actually crushed during the test, which often is not the case. Moreover, the term *strength* in this application can be questioned, because in the physical sciences that term is often used to describe a stress (e.g., tensile strength). Thus, the term *breaking force* is preferred and will be used in the present discussion.

TABLET BREAKING FORCE DETERMINATIONS

Early measuring devices were typically hand operated. For example, the Monsanto (or Stokes) hardness tester was based on compressing tablets between two jaws via a spring gauge and screw. In the Pfizer hardness tester, the vertically mounted tablet was squeezed in a device that resembled a pair of pliers. In the Strong Cobb hardness tester, the break-

ing load was applied through the action of a small hydraulic pump that was first operated manually but was later motorized. Problems associated with these devices were related to operator variability in rates of loading and difficulties in proper setup and calibration. Modern testers employ mechanical drives, strain gauge-based load cells for force measurements, and electronic signal processing, and therefore are preferred. However, several important issues must be considered when using them for the analytical determination of breaking force; these are discussed below.

Platens

The platens should be parallel. Their faces should be polished smooth and precision-ground perpendicularly to the direction of movement. Perpendicularity must be preserved during platen movement, and the mechanism should be free of any bending or torsion displacements as the load is applied. The contact faces must be larger than the area of contact with the tablet.

Rate and Uniformity of Loading

Either the rate of platen movement or the rate at which the compressive force is applied (i.e., the loading rate) should be constant. Maintaining a constant loading rate avoids the rapid buildup of compressive loads, which may lead to uncontrolled crushing or shear failure and greater variability in the measured breaking force. However, constant loading rate measurements may be too slow for real time monitoring of tablet production.

The rate at which the compressive load is applied can significantly affect results, because time-dependent processes may be involved in tablet failure (1). How a tablet matrix responds to differences in the loading rate depends on the mechanism of failure. At low strain rates, some materials may fail in a ductile manner, but brittle failure is more likely at faster strain rates. The transition from ductile to brittle failure is accompanied by an increase in the breaking force. Devices that simply crush tablets may produce deceptively reproducible data because they lack sensitivity.

The test must be run consistently with equipment which has been routinely calibrated. Changing from testing units of different designs or from different manufacturers will require comparison of data to ensure that the two units are subjecting the dosage form to similar stress in a similar manner. Currently available equipment provides a constant loading rate of 20 newtons (N) or less per second or a constant platen movement of 3.5 mm or less per second. Controlled and consistent breaking is an important test procedure attribute. To ensure comparability of results, testing must occur under identical conditions of loading rate or platen movement rate. Since there are certain advantages to each system of load application, both are found in practice. Because the particular testing situation and the type of tablet matrix being evaluated will pose different constraints, there is also no basis to declare an absolute preference for one system over the other. This general chapter proposes consideration of both approaches.

The different methods may lead to numerically different results for a particular tablet sample, requiring that the rate of load application or displacement must be specified along with the determined breaking force.

Dependence of Breaking Force on Tablet Geometry and Mass

Measurements of breaking force do not take into account the dimensions or shape of the tablet. Thicker tablets of the same material compressed under conditions identical to those of thinner tablets, with the same tooling shape and to the same peak force, will require greater breaking forces. Tablet orientation and failure should occur in a manner con-

sistent with those used during the development of the dosage form. For direct comparisons (i.e., without any normalizations of the data), breaking force measurements should be performed on tablets having the same dimensions, geometry, and consistent orientation in test equipment.

Tablet Orientation

Tablet orientation in diametral compression of round tablets without any scoring is unequivocal. That is, the tablet is placed between the platens so that compression occurs across a diameter. However, tablets with a unique or complex shape may have no obvious orientation for breaking force determination. Because the breaking force may depend on the tablet's orientation in the tester, to ensure comparability of results, it is best to settle on a standard orientation, preferably one that is most readily and easily reproduced by operators. In general, tablets are tested either across the diameter or parallel to the longest axis. Scored tablets have two orientation possibilities. When they are oriented with their scores perpendicular to the platen faces, the likelihood that tensile failure will occur along the scored line increases. This provides information about the strength of the matrix at the weakest point in the structure. When scored tablets are oriented with their scores parallel to the platen faces, more general information about the strength of the matrix is derived.

Capsule-shaped tablets or scored tablets may best be broken in a three-point flexure test (2). A fitting, which is either installed on the platens or substituted for the platens, supports the tablet at its ends and permits the breaking load to be applied to the opposite face at the unsupported midpoint of the tablet. The fittings are often available from the same source that supplies the hardness tester.

Units, Resolution, and Calibration

Modern breaking force testers are usually calibrated in kiloponds or newtons. The relationship between these units of force (3) is 1 kilopond (kp) = 1 kilogram-force (kgf) = 9.80 N. The test results should be expressed in standard units of force which facilitate communication. Some breaking force testers also will provide a scale in Strong Cobb units (SCU), a carryover from the days when Strong Cobb hardness testers were in common usage. The conversion between SCU and N or kp must be viewed with caution, because the SCU is derived from a hydraulic device and is a pressure.

Generally, contemporary breaking force testers use modern electronic designs with digital readouts. Some units also have an integral printer or may be interfaced with a printer. Breaking forces should be readable to within 1 N.

Breaking force testers should be calibrated periodically. The force sensor as well as the mechanics of the apparatus needs to be considered. For the force sensor, the complete measuring range (or, at a minimum, the range used for measuring the test sample) should be calibrated to a precision of 1 N, using either the static or dynamic method. Static calibration generally employs traceable counterweights; at least three different points are checked to assess linearity. Dynamic calibration makes use of a traceable reference-load cell that is compressed between the platens. The functional calibration of a breaking force test apparatus should also confirm that the velocity and the constancy of velocity for load application or displacement are within prescribed tolerances throughout the range of platen movement.

Sample Size

In order to achieve sufficient statistical precision for the determination of average breaking force, a minimum of 6 tablet samples should be tested. The average breaking force

alone may be adequate to fulfill the purpose of process or product quality control. In cases where breaking force may be particularly critical, the average plus individual breaking force values should be accessible.

TENSILE STRENGTH

The measurement of tensile strengths provides a more fundamental measure of the mechanical strength of the compacted material and takes into account the geometry of the tablet. If tablets fail in tension, the breaking force can be used to calculate the tensile strength. Unfortunately, this is practical only for simple shapes. If flat-faced round tablets (right circular cylinders) fail in tension, as indicated by a clean split into halves under diametral compression, the breaking force may be used to compute the tensile strength from the following equation (4), which applies only to cylindrical tablets:

$$\sigma_x = 2F/\pi DH$$

in which σ_x is the tensile strength, F is the breaking force, D is the tablet diameter, and H is the tablet thickness. Because only tablets that fail in tension are counted, the data are based on tablets that fail in a consistent way. Thus, reproducibility of data should be enhanced when compared to conventional breaking-strength testing. Moreover, the data will be normalized with respect to tablet dimensions, because both diameter and thickness are included in the equation. The derivation of this equation may be found in standard texts (5, 6); it is based on elastic theory and the following assumptions:

1. The tablet is an isotropic body
2. Hooke's law is obeyed
3. The modulus of elasticity in compression and in tension is the same
4. Ideal point loading occurs

The derivation has been extended to convex-faced tablets (7, 8):

$$\sigma_x = (10F/\pi D^2) \times [(2.84H/D) - (0.126H/W) + (3.15W/D) + 0.01]^{-1}$$

where σ_x is the tensile strength, F is the breaking force, D is the tablet diameter, H is the tablet thickness, and W is the central cylinder thickness (tablet wall height).

The slow and constant loading rate of modern motorized break force testers encourages tensile failure. However, ideal point loading may not occur, because of crushing and the induction of shear failure at the interface with the surface of the platens. The addition of padding to the platens helps prevent shear at contact points and promotes true tensile failure. On that basis, padding is strongly recommended when highly precise measurements are needed. Padding should be relatively thin so that any deviation from the assumption of true point-source force application will not be large. The padding should also collapse very easily so that its deformation does not become part of the force measured by the test apparatus. In more routine settings involving measurements on a large number of samples, the addition of padding could contribute to inaccuracies in measurement as powder from previously tested samples becomes embedded in the collapsible matrix and thereby alters its properties. Unless provisions for frequent and routine replacement of the padding are made, it can be considered acceptable to ignore the use of padding material to maintain constancy of the test conditions.

Bending or flexure of tablets is another option for determining the tensile strength of tablets. Under ideal loading conditions, a breaking load applied to the unsupported midpoint of one face will result in the generation of pure tensile stress in the opposite face. If the tablets are right circular cylinders and are subjected to three-point flexure, the ten-

sile strength may be estimated using the following equation (9):

$$\sigma_x = 3FL/2H^2D$$

in which L is the distance between supports, and the other terms are as defined above. The assumptions are the same as those for calculating tensile strength from diametral compression. However, tensile strengths determined by flexure and diametral compression may not agree, because of likely nonideal loading and the induction of shear failure during testing.

<1222> TERMINALLY STERILIZED PHARMACEUTICAL PRODUCTS—PARAMETRIC RELEASE

INTRODUCTION

Parametric release is defined as the release of terminally sterilized batches or lots of sterile products based upon compliance with the defined critical parameters of sterilization without having to perform the requirements under *Sterility Tests* <71>. Parametric release is a possibility when the mode of sterilization is very well understood, the physical parameters of processing are well defined, predictable, and measurable, and the lethality of the cycle has been microbiologically validated through the use of appropriate biological indicators or, in the case of ionizing radiation, the appropriate microbiological and dosimetric tests. The use of parametric release for sterilization processes requires prior FDA approval. It should be expected that the regulatory agencies evaluating submissions including the use of parametric product release would insist upon a well supported

scientific rationale for the sterilization process and well documented validation data. The agencies would need assurance that any marketed sample of product will be sterile and if tested after release would pass the requirements for sterility as found in the general chapter *Sterility Tests* (71).

It is important to consider the limitations of the *Sterility Tests* (71) in the evaluation of terminally sterilized products. The sterility test described in general chapter (71) is limited in its sensitivity and is statistically ill-suited to the evaluation of terminally sterilized products given the exceedingly low probability of contaminated units. Therefore, *once a sterilization process is fully validated and operates consistently*, a combination of physical sterilization data such as accumulated lethality or dosimetry in combination with other methods, such as load monitors (e.g., biological indicators, thermochemical indicators, or physicochemical integrators), can provide more accurate information than the sterility test regarding the release of terminally sterilized product to the marketplace.

There are four modes of sterilization that theoretically and practically could qualify for parametric release: moist heat, dry heat, ethylene oxide, and ionizing radiation sterilization. This information chapter first will cover the general issues related to parametric release, regardless of the modes of sterilization, and then discuss some specific modes of sterilization. The chapter will *not* address the parametric release of terminally sterilized medical devices.

Terminally sterilized products represent the lowest risk category of sterile pharmaceutical products. Unlike products aseptically manufactured in a microbiologically controlled environment, terminally sterilized products are subjected to a sterilization process that imparts a measurable minimum sterility assurance level, or SAL. Because aseptic processing relies on exclusion of microbiological contamination and is not based upon lethality imparted on the product in its sealed container, it is not possible to estimate the SAL. It is important to note that in the case of aseptic processing, SAL can only be estimated from media fill contamination rates or other forms of risk assessment. In the case of terminal sterilization, it is possible to calculate a minimum SAL or Probability of Nonsterility (PNS) quite accurately. Therefore, the term SAL has different contextual meanings when used to describe aseptic rather than terminal processes, and it is important that this difference is fully understood by scientists and engineers working in the field of sterile product manufacturing and control. The terms PNS and SAL are often used interchangeably.

Terminally sterilized products must have a probability of nonsterility (PNS) of not more than one in a million units produced. This is often stated as a PNS or SAL of 10^{-6} , or the probability of product bioburden surviving the sterilization process in any single unit of product is less than one in one million. The proof that a terminally sterilized product complies with the 10^{-6} PNS can be accomplished by several different sterilization cycle development approaches. The proper application of these methods requires extensive scientific knowledge regarding the sterilization method selected for use with a specific product.

The strategies used to validate a terminal sterilization process development fall into three categories:

1. Bioburden-based process.
2. Biological indicator/bioburden combined process.
3. Overkill process.

The bioburden-based process requires extensive knowledge of product bioburden. It should be noted that several radiation dose-setting procedures involve establishing radiation processes on the basis of bioburden count and radiation resistance. This method requires that at least a 10^{-6} PNS be attained for bioburden by the sterilization process. This means that if the product bioburden action level is 10 microorganisms or one logarithm, at least seven logarithms of bioburden must be inactivated to assure a 10^{-6} PNS. The bioburden-based method requires the user to develop suitable critical control points within the process to control the bioburden titer. Products that readily permit bioburden sur-

vival require more controlled manufacturing environments and more precise in-process control. This process is better suited for cycle development for clean or ultra-clean products containing a consistently low level of colony forming units (cfu) per product unit with a low frequency of spore-forming microorganisms. Also, this process may be necessary to permit terminal sterilization of a product that may potentially lose key qualities or attributes as a result of a more rigorous sterilization process.

The microbiologist may find that formal hazard analysis procedures, such as Hazard Analysis Critical Control Point (HACCP), are useful in establishing appropriate manufacturing control conditions and in-process control parameters.

The biological indicator/bioburden combined process is generally used when the manufacturer desires a sterilization process that demonstrates the inactivation of high numbers of biological indicator microorganisms known to be resistant to the process. While the manufacturer may have preferred utilizing an overkill process, potential loss of some product attributes may occur in an overkill process thereby necessitating the use of a biological indicator/bioburden combined process. This process requires knowledge of the bioburden load on and in the product, and a database relative to the sterilization resistance of the bioburden. The relative resistance of the selected biological indicator to that of the bioburden must be established on or in the product. Frequently, biological indicators bearing approximately 10^6 spores with D_{121} -value > 1 minute are used in the development of such processes. Fractional exposure cycles are generally conducted to determine the relative sterilization resistance (or D value) between product inoculated with the biological indicator microorganism(s) and frequently encountered bioburden. This process is frequently used for sterilization cycle development by manufacturers of terminally sterilized parenteral products and for ethylene oxide sterilization of medical devices.

The overkill process is frequently used when the article being sterilized is completely inert to the sterilizing agent and sterilization cycle conditions without any concern for loss of product attributes or quality. When using this process, some bioburden knowledge should be available to ensure that the materials are not adulterated before sterilization. These data may include product bioburden count data and knowledge concerning the prevalence of spore formers. The database for this process need not be as extensive as bioburden data required for the bioburden process or the biological indicator/bioburden process. Generally, process-resistant biological indicators containing approximately 10^6 spores are used to establish the effectiveness of the sterilization process. However, a spore population of N_0 can be chosen to confirm adequate process lethality. Overkill is generally defined as a process that would deliver a minimum of F_0^1 of 12 minutes (see *Critical Operating Parameters* below) and is demonstrated biologically based upon the spore log reduction of calibrated biological indicators.

GENERAL REVIEW

Validation of Sterilization Process

Parametric release first requires that the chosen sterilization process be designed and validated to achieve a 10^{-6} PNS. Validation of most sterilization processes includes the validation of physical parameters of the process and of its microbiological effectiveness through the use of biological indicators. However, the use of biological indicators for establishing or periodically validating gamma radiation sterilization processes is uncommon. Widely recognized biological indicator organisms are used in the validation of moist heat

¹ F_0 is defined as the calculated equivalent time (in minutes) of process lethality to time at 121.1°, assuming a Z value of 10.0° in the product being sterilized.

processes because they provide a means of comparing physically measured lethality data with biological lethality. There should be a reasonable correlation between physically measured lethality data (F_0) and biological lethality as determined by the evaluation of the process with biological indicators.

The predictable effectiveness of bioburden-based terminal sterilization is based on the number and resistance of microorganisms on or in a product. For this reason, one component of parametric release is an active microbiology control program to monitor the count and sterilization resistance of product bioburden. Bioburden control and enumeration is of far less significance when the overkill process design is used. In many cases, overkill processes do not require extensive ongoing assessment of bioburden and require less in-process control of the manufacturing environment.

Sterilization Microbiology Control Program

The purpose of this control program is to ensure that the microbiological status of the product, *prior to being terminally sterilized*, has not significantly deviated from the established microbiological control level used for validation of the sterilization process. The microbiology control program includes the monitoring of the bioburden on or in the product and the monitoring of the microbiological status of any necessary containers, closures, or packaging materials. Also included is a program to evaluate the microbiological status of the environment where the product is processed. The control program is particularly important in cases where the terminal sterilization is not based on overkill, but rather on the bioburden or combined bioburden/biological indicator cycle development approach. In many cases, bioburden control and manufacturing environmental monitoring will not be required for overkill process designs, where the F_0 of the process is at least 12 minutes. In other cases, even when overkill processes are employed, some limited monitoring will be needed. Monitoring of overkill processes for bioburden is generally limited to those products that support microbial growth. Of particular concern in this case is the potential for the product to be contaminated with microbial toxins or to be degraded by microorganisms.

The frequency of monitoring will depend on the variations of bioburden from potential sources. The number of microorganisms, their identification, as well as their resistance to the specified sterilization mode should be considered when parametric release of terminally sterilized product is established. Resistance to a specified sterilization mode by different species can influence sterilization effectiveness and the determination of sterilization process conditions when using the bioburden or combined bioburden/biological indicator method of cycle development. In the bioburden approach to process development, indicator organisms more resistant than typical bioburden may be used, although extreme differentials in resistance are not required. Information on the performance of biological indicators may be found in the general chapter *Biological Indicators—Resistance Performance Tests* (55).

Change Control System

Changes introduced to the sterilization processing equipment could result in a significant departure of the initially validated parametric release process. It is, therefore, essential that a change control system be instituted. A change control system is a formal system with appropriate standard operating procedures, which would include approval of changes in the sterilization processing equipment. This system would assess all the changes in relation to the critical parameters included in parametric release. The change control system also includes technical and management review and criteria for acceptance or revision of changes. If a change would significantly affect any critical parameter, each parameter would have to be revalidated in terms of

sterility assurance of the pharmaceutical product to a minimum 10^{-6} PNS. Appropriate regulatory notification would also be part of the revalidation process.

Release Procedures

A quality assurance program should be established that describes in detail the batch or lot release steps for parametric release of sterilized products and the required documentation. Although the assessment of the sterility assurance of products is primarily based on measurement of physical process parameters, a number of areas should be reviewed, documented, and approved for the parametric release of these products. These areas may include the following: a review of batch records; a review of the ongoing microbiological environmental control program results and presterilization bioburden; and a review of records of thermographic data, load monitors, and results of critical and noncritical data that may have been used to demonstrate process control. It is also important to ensure that the sterilizer is current relative to calibration, maintenance, and revalidation.

The implementation and practice of parametric release is not an intermittent program. Once such a program is implemented, release of the sterilized product is made in accordance with the requirements of the regulatory approved program. Product release by other means is not acceptable if the predefined critical operational parameters are not achieved.

MODES OF STERILIZATION

Moist Heat Sterilization

Moist heat sterilization of pharmaceutical products includes several types of sterilizing environments and sterilizing media. Saturated steam, hot water spray, and submerged hot water processes are all considered as moist heat sterilizing environments. Different processes may be used to sterilize products by moist heat, and they include batch-type sterilizers and continuous-type sterilizers.

CRITICAL OPERATING PARAMETERS

A defined list of key process parameters and their respective operating limits are defined and established in the sterilization process specifications. Critical operating parameters are those that are absolutely essential to ensure product sterilization to a 10^{-6} PNS. Examples of critical operating parameters may include, but are not limited to, dwell time limits, minimum and maximum limits for process peak dwell temperature, average peak dwell temperature, and the results of the batch or lot release test that satisfies the requirements of CFR, Part 211 (e.g., a load monitor results from the laboratory). F_0 may be used as a critical parameter only when temperature and time relationships are well defined. Other measured parameters may be considered secondary (or noncritical) parameters and may include maximum and minimum time to peak dwell, chamber pressure, and if applicable, chamber water level, sterilizing water time above defined temperature limits, and recirculating water pump pressure differential.

Ethylene Oxide Sterilization

The application of parametric release of pharmaceutical products sterilized by ethylene oxide is more difficult than parametric release of products sterilized by moist heat processes. Critical parameters for ethylene oxide (ETO) steril-

ization are interrelated and more complex than moist heat processes.

CRITICAL OPERATING PARAMETERS

Critical parameters may include the following: temperature, amount of relative humidity present, ethylene oxide concentration, overall exposure time, product and load density, and gas permeability factors.

Parametric release of pharmaceutical products can be achieved if an automated measurement system for the critical parameters is employed and sterilization loads are closely defined and validated relative to product types, densities, packaging materials, and overall load configurations. An example of the measurement of critical factors that may be considered for parametric release would be the use of calibrated ETO pressure recordings to provide an estimate of ETO concentration during the process hold time or the use of direct measurement of ETO concentration by IR or gas chromatography. Because of variances that might occur in the key parameters during sterilization, parametric release is not widely used for products sterilized by ETO.

However, to ensure parametric release, in addition to the attainment of process parameters of the ethylene oxide sterilization, biological indicators (and their sterility testing after sterilization processing) or the use of physicochemical integrators for the ethylene oxide sterilization are often used as load monitors (critical parameters).

Radiation Sterilization

Two radiation sterilizing processes have been used: gamma and electron beam sterilization (i.e., ionizing radiation). Some pharmaceutical products, either in bulk or in their finished formats, have been sterilized by radiation. In discussing the critical parameters of radiation sterilization necessary for parametric release, it is customary to refer to parametric release as *dosimetric release*. Dosimetric release is provided by the use of a chemical dosimeter that measures the delivery of a minimum specified radiation dosage, which has been shown to provide sterilization of the product to a minimum 10^{-6} PNS.

The use of a dosimeter in ionizing radiation sterilization measures delivery of a minimum absorbed radiation dose to a pre-established low dose zone in the irradiated product carrier. This will require mapping of the profile of absorbed ionizing radiation across the density ranges processed in the product carrier. The lowest specified radiation dosage for the process is correlated to predictable bioburden reduction levels by any one of the three documented methods.² An alternative method may be considered whereby extensive product bioburden count and radiation resistance data are available. Dose verification studies would be conducted to ensure that the worst case bioburden load, relative to resistance and numbers, can be inactivated at the lowest dose zone in the carrier system to provide at least a 10^{-6} PNS. This method would of course require an ongoing program of bioburden assessment. The target for the radiation cycle is a minimum 10^{-6} PNS relative to the product bioburden. Dosimetric release of a radiation-sterilized product depends on the delivery of at least a minimum dosage; thus, the critical operational parameters that govern the delivery of that dosage must be within specified limits. These operational critical parameters may include the following: a stacking configuration within the radiation carrier, bulk density of the product, speed of the conveyor or carrier system, distance to the radiation source, duration of product exposure, and appropriate defined adjustments for a decaying radiation source. Demonstration of consistency in the absorbed radiation dosage at areas of minimum and maximum zones of radiation absorption within the fully loaded carriers on a

batch-to-batch basis is a necessary condition for dosimetric release of radiation-sterilized pharmaceutical products.

SUMMARY

The conversion to parametric release in lieu of product sterility testing as described in general chapter *Sterility Tests* <71> requires prior FDA approval. Parametric release is advantageous for terminally sterilized products. The extensiveness of data required to establish parametric release, compared to the general chapter <71> procedures, which lack sensitivity to very low levels of microbial contamination, can result in a more accurate and reliable assessment of the probability of nonsterility of product lots.

<1223> VALIDATION OF ALTERNATIVE MICROBIOLOGICAL METHODS

INTRODUCTION

The purpose of this chapter is to provide guidance for validating methods for use as alternatives to the official compendial microbiological methods. For microbial recovery and identification, microbiological testing laboratories sometimes use alternative test methods to those described in the general chapters for a variety of reasons, such as economics, throughput, and convenience. Validation of these methods is required. Some guidance on validation of the use of alternate methods is provided in the *Tests and Assays* section in the *General Notices and Requirements*. This section also notes that in the event of a dispute, only the result obtained by the compendial test is conclusive.

Validation studies of alternate microbiological methods should take a large degree of variability into account. When conducting microbiological testing by conventional plate count, for example, one frequently encounters a range of results that is broader (%RSD 15 to 35) than ranges in commonly used chemical assays (%RSD 1 to 3). Many conventional microbiological methods are subject to sampling error, dilution error, plating error, incubation error, and operator error.

Validation of Compendial Procedures <1225> defines characteristics such as accuracy, precision, specificity, detection limit, quantification limit, linearity, range, ruggedness, and robustness in their application to analytical methods. These definitions are less appropriate for alternate microbiological method validation as "at least equivalent to the compendial method" given the comparative nature of the question (see the *Tests and Assays—Procedures* section in *General Notices and Requirements*). The critical question is whether or not the alternate method will yield results equivalent to, or better than, the results generated by the conventional method.

Other industry organizations have provided guidance for the validation of alternate microbiological methods.* The suitability of a new or modified method should be demonstrated in a comparison study between the USP compendial method and the alternate method. The characteristics defined in this chapter may be used to establish this comparison.

TYPES OF MICROBIOLOGICAL TESTS

It is critical to the validation effort to identify the portion of the test addressed by an alternate technology. For example, there is a variety of technologies available to detect the presence of viable cells. These techniques may have application in a variety of tests (e.g., bioburden, sterility test) but may not, in fact, replace the critical aspects of the test entirely. For example, a sterility test by membrane filtration may be performed according to the compendial procedure up to the point of combining the processed filter with the recovery media, and after that the presence of viable cells might then be demonstrated by use of some of the available technologies. Validation of this application would, therefore, require validation of the recovery system employed rather than the entire test.

There are three major types of determinations specific to microbiological tests. These include tests to determine whether microorganisms are present in a sample, tests to quantify the number of microorganisms (or to enumerate a specific subpopulation of the sample), and tests designed to identify microorganisms. This chapter does not address microbial identification.

Qualitative Tests for the Presence or Absence of Microorganisms

This type of test is characterized by the use of turbidity in a liquid growth medium as evidence of the presence of viable microorganisms in the test sample. The most common example of this test is the sterility test. Other examples of this type of testing are those tests designed to evaluate the presence or absence of a particular type of microorganism in a sample (e.g., coliforms in potable water and *E. coli* in oral dosage forms).

Quantitative Tests for Microorganisms

The plate count method is the most common example of this class of tests used to estimate the number of viable microorganisms present in a sample. The membrane filtration and Most Probable Number (MPN) multiple-tube methods are other examples of these tests. The latter was developed as a means to estimate the number of viable microorganisms present in a sample not amenable to direct plating or membrane filtration.

General Concerns

Validation of a microbiological method is the process by which it is experimentally established that the performance characteristics of the method meet the requirements for the intended application, in comparison to the traditional method. For example, it may not be necessary to fully validate the equivalence of a new quantitative method for use in the antimicrobial efficacy test by comparative studies, as the critical comparison is between the new method of enumeration and the plate count method (the current method for enumeration). As quantitative tests, by their nature, yield numerical data, they allow for the use of parametric statistical techniques. In contrast, qualitative microbial assays, e.g., the sterility test in the example above, may require analysis by nonparametric statistical methods. The validation of analytical methods for chemical assays follows well-established parameters as described in *Validation of Compendial Procedures* (1225). Validation of microbiological methods shares some of the same concerns, although consideration must be given to the unique nature of microbiological assays (see Table 1).

Table 1. Validation Parameters by Type of Microbiological Test

Parameter	Qualitative Tests	Quantitative Tests
Accuracy	No	Yes
Precision	No	Yes
Specificity	Yes	Yes
Detection limit	Yes	Yes
Quantification limit	No	Yes
Linearity	No	Yes
Operational range	No	Yes
Robustness	Yes	Yes
Repeatability	Yes	Yes
Ruggedness	Yes	Yes

VALIDATION OF QUALITATIVE TESTS FOR DEMONSTRATION OF VIABLE MICROORGANISMS IN A SAMPLE

Specificity

The specificity of an alternate qualitative microbiological method is its ability to detect a range of microorganisms that may be present in the test article. This concern is adequately addressed by growth promotion of the media for qualitative methods that rely upon growth to demonstrate presence or absence of microorganisms. However, for those methods that do not require growth as an indicator of microbial presence, the specificity of the assay for microbes assures that extraneous matter in the test system does not interfere with the test.

Limit of Detection

The limit of detection is the lowest number of microorganisms in a sample that can be detected under the stated experimental conditions. A microbiological limit test determines the presence or absence of microorganisms, e.g., absence of *Salmonella* spp. in 10 g. Due to the nature of microbiology, the limit of detection refers to the number of organisms present in the original sample before any dilution or incubation steps; it does not refer to the number of organisms present at the point of assay.

One method to demonstrate the limit of detection for a quantitative assay would be to evaluate the two methods (alternative and compendial) by inoculation with a low number of challenge microorganisms (not more than 5 cfu per unit) followed by a measurement of recovery. The level of inoculation should be adjusted until at least 50% of the samples show growth in the compendial test. It is necessary to repeat this determination several times, as the limit of detection of an assay is determined from a number of replicates (not less than 5). The ability of the two methods to detect the presence of low numbers of microorganisms can be demonstrated using the Chi square test. A second method to demonstrate equivalence between the two quantitative methods could be through the use of the Most Probable Number technique. In this method, a 5-tube design in a ten-fold dilution series could be used for both methods. These would then be challenged with equivalent inoculums (for example, a 10⁻¹, 10⁻², and 10⁻³ dilution from a stock suspension of approximately 50 cfu per mL to yield target inocula of 5, 0.5, and 0.05 cfu per tube) and the MPN of the original stock determined by each method. If the 95% confidence intervals overlapped, then the methods would be considered equivalent.

Ruggedness

The ruggedness of a qualitative microbiological method is the degree of precision of test results obtained by analysis of the same samples under a variety of normal test conditions, such as different analysts, instruments, reagent lots, and laboratories. Ruggedness can be defined as the intrinsic resistance to the influences exerted by operational and environmental variables on the results of the microbiological method. Ruggedness is a validation parameter best suited to determination by the supplier of the test method who has easy access to multiple instruments and batches of components.

Robustness

The robustness of a qualitative microbiological method is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters, and provides an indication of its reliability during normal usage. Robustness is a validation parameter best suited to determination by the supplier of the test method. As there are no agreed upon standards for current methods, acceptance criteria are problematic and must be tailored to the specific technique. It is essential, however, that an estimate of the ruggedness of the alternate procedure be developed. The measure of robustness is not necessarily a comparison between the alternate method and the traditional, but rather a necessary component of validation of the alternate method so that the user knows the operating parameters of the method.

VALIDATION OF QUANTITATIVE ESTIMATION OF VIABLE MICROORGANISMS IN A SAMPLE

As colony-forming units follow a Poisson distribution, the use of statistical tools appropriate to the Poisson rather than those used to analyze normal distributions is encouraged. If the user is more comfortable using tools geared towards normally distributed data, the use of a data transformation is frequently useful. Two techniques are available and convenient for microbiological data. Raw counts can be transformed to normally distributed data either by taking the \log_{10} unit value for that count, or by taking the square root of count +1. The latter transformation is especially helpful if the data contain zero counts.

Accuracy

The accuracy of this type of microbiological method is the closeness of the test results obtained by the alternate test method to the value obtained by the traditional method. It should be demonstrated across the operational range of the test. Accuracy is usually expressed as the percentage of recovery of microorganisms by the assay method.

Accuracy in a quantitative microbiological test may be shown by preparing a suspension of microorganisms at the upper end of the range of the test, that has been serially diluted down to the lower end of the range of the test. The operational range of the alternate method should overlap that of the traditional method. For example, if the alternate method is meant to replace the traditional plate count method for viable counts, then a reasonable range might be from 10^0 to 10^6 cfu per mL. At least 5 suspensions across the range of the test should be analyzed for each challenge organism. The alternate method should provide an estimate of viable microorganisms not less than 70% of the estimate provided by the traditional method, or the new method should be shown to recover at least as many organisms as the traditional method by appropriate statistical analysis, an example being an ANOVA analysis of the \log_{10} unit trans-

forms of the data points. Note that the possibility exists that an alternate method may recover an apparent higher number of microorganisms if it is not dependent on the growth of the microorganisms to form colonies or develop turbidity. This is determined in the *Specificity* evaluation.

Precision

The precision of a quantitative microbiological method is the degree of agreement among individual test results when the procedure is applied repeatedly to multiple samplings of suspensions of laboratory microorganisms across the range of the test. The precision of a microbiological method is usually expressed as the standard deviation or relative standard deviation (coefficient of variation). However, other appropriate measures may be applied.

One method to demonstrate precision uses a suspension of microorganisms at the upper end of the range of the test that has been serially diluted down to the lower end of the range of the test. At least 5 suspensions across the range of the test should be analyzed. For each suspension at least 10 replicates should be assayed in order to be able to calculate statistically significant estimates of the standard deviation or relative standard deviation (coefficient of variation). Generally, a RSD in the 15% to 35% range would be acceptable. Irrespective of the specific results, the alternate method should have a coefficient of variation that is not larger than that of the traditional method. For example, a plate count method might have the RSD ranges as shown in the following table.

Table 2. Expected RSD as a Function of cfu per Plate

cfu per Plate	Expected RSD
30–300	<15%
10–30	<25%
<10	<35%

Specificity

The specificity of a quantitative microbiological method is its ability to detect a panel of microorganisms suitable to demonstrate that the method is fit for its intended purpose. This is demonstrated using the organisms appropriate for the purpose of the alternate method. It is important to challenge the alternate technology in a manner that would encourage false positive results (specific to that alternate technology) to demonstrate the suitability of the alternate method in comparison to the traditional method. This is especially important with those alternate methods that do not require growth for microbial enumeration (for example, any that do not require enrichment or can enumerate microorganisms into the range of 1–50 cells).

Limit of Quantification

The limit of quantification is the lowest number of microorganisms that can be accurately counted. As it is not possible to obtain a reliable sample containing a known number of microorganisms, it is essential that the limit of quantification of an assay is determined from a number of replicates ($n > 5$) at each of at least 5 different points across the operational range of the assay. The limit of quantification should not be a number greater than that of the traditional method. Note that this may have an inherent limit due to the nature of bacterial enumeration and the Poisson distribution of bacterial counts (see *Validation of Microbial Recovery from Pharmacopeial Articles* <1227>). Therefore, the alternate method need only demonstrate that it is at least as sensitive as the traditional method to similar lower limits.

Linearity

The linearity of a quantitative microbiological test is its ability to produce results that are proportional to the concentration of microorganisms present in the sample within a given range. The linearity should be determined over the range of the test. A method to determine this would be to select at least 5 concentrations of each standard challenge microorganism and conduct at least 5 replicate readings of each concentration. An appropriate measure would be to calculate the square of the correlation coefficient, r^2 , from a linear regression analysis of the data generated above. While the correlation coefficient does not provide an estimate of linearity, it is a convenient and commonly applied measure to approximate the relationship. The alternate method should not have an r^2 value less than 0.95.

Limit of Detection

See *Limit of Detection* under *Validation of Qualitative Tests for Demonstration of Viable Microorganisms in a Sample*.

Range

The operational range of a quantitative microbiological method is the interval between the upper and lower levels of microorganisms that have been demonstrated to be determined with precision, accuracy, and linearity.

Ruggedness

See *Ruggedness* under *Validation of Qualitative Tests for Demonstration of Viable Microorganisms in a Sample*.

Robustness

See *Robustness* under *Validation of Qualitative Tests for Demonstration of Viable Microorganisms in a Sample*.

(1224) TRANSFER OF ANALYTICAL PROCEDURES

INTRODUCTION

Testing to the specification of an ancillary material, intermediate, and/or ingredient and product is critical in establishing the quality of a finished dosage form. The transfer of analytical procedures (TAP), also referred to as method transfer, is the documented process that qualifies a laboratory (the receiving unit) to use an analytical test procedure that originated in another laboratory (the transferring unit), thus ensuring that the receiving unit has the procedural knowledge and ability to perform the transferred analytical procedure as intended.

The purpose of this general information chapter is to summarize the types of transfers that may occur, including the possibility of waiver of any transfer, and to outline the potential components of a transfer protocol. The chapter does not provide statistical methods and does not encompass the transfer of microbiological or biological procedures.

TYPES OF TRANSFERS OF ANALYTICAL PROCEDURES

TAP can be performed and demonstrated by several approaches. The most common is comparative testing performed on homogeneous lots of the target material from standard production batches or samples intentionally prepared for the test (e.g., by spiking relevant accurate amounts of known impurities into samples). Other approaches include covalidation between laboratories, the complete or partial validation of the analytical procedures by the receiving unit, and the transfer waiver, which is an appropriately justified omission of the transfer process. The tests that will be transferred, the extent of the transfer activities, and the implementation strategy should be based on a risk analysis that considers the previous experience and knowledge of the receiving unit, the complexity and specifications of the product, and the procedure.

Comparative Testing

Comparative testing requires the analysis of a predetermined number of samples of the same lot by both the sending and the receiving units. Other approaches may be valid, e.g., if the receiving unit meets a predetermined acceptance criterion for the recovery of an impurity in a spiked product. Such analysis is based on a preapproved transfer protocol that stipulates the details of the procedure, the samples that will be used, and the predetermined acceptance criteria, including acceptable variability. Meeting the predetermined acceptance criteria is necessary to assure that the receiving unit is qualified to run the procedure.

Covalidation Between Two or More Laboratories

The laboratory that performs the validation of an analytical procedure is qualified to run the procedure. The transferring unit can involve the receiving unit in an interlaboratory covalidation, including them as a part of the validation team at the transferring unit and thereby obtaining data for the assessment of reproducibility. This assessment is made using a preapproved transfer or validation protocol that provides the details of the procedure, the samples to be used, and the predetermined acceptance criteria. The general chapter *Validation of Compendial Procedures* (1225) provides useful guidance about which characteristics are appropriate for testing.

Revalidation

Revalidation or partial revalidation is another acceptable approach for transfer of a validated procedure. Those characteristics described in (1225), which are anticipated to be affected by the transfer, should be addressed.

Transfer Waiver

The conventional TAP may be omitted under certain circumstances. In such instances, the receiving unit is considered to be qualified to use the analytical test procedures without comparison and generation of interlaboratory comparative data. The following examples give some scenarios that may justify the waiver of TAP:

- The new product's composition is comparable to that of an existing product and/or the concentration of active ingredient is similar to that of an existing product and is analyzed by procedures with which the receiving unit already has experience.
- The analytical procedure being transferred is described in the *USP-NF*, and is unchanged. Verification should apply in this case (see (1226)).

- The analytical procedure transferred is the same as or very similar to a procedure already in use.
- The personnel in charge of the development, validation, or routine analysis of the product at the transferring unit are moved to the receiving unit.

If eligible for transfer waiver, the receiving receiving unit should document it with appropriate justifications.

ELEMENTS RECOMMENDED FOR THE TRANSFER OF ANALYTICAL PROCEDURES

Several elements, many of which may be interrelated, are recommended for a successful TAP. When appropriate and as a part of pretransfer activities, the transferring unit should provide training to the receiving unit, or the receiving unit should run the procedures and identify any issues that may need to be resolved before the transfer protocol is signed. Training should be documented.

The transferring unit, often the development unit, is responsible for providing the analytical procedure, the reference standards, the validation reports, and any necessary documents, as well as for providing the necessary training and assistance to the receiving unit as needed during the transfer. The receiving unit may be a quality control unit, another intracompany facility, or another company such as a contract research organization. The receiving unit provides qualified staff or properly trains the staff before the transfer, ensures that the facilities and instrumentation are properly calibrated and qualified as needed, and verifies that the laboratory systems are in compliance with applicable regulations and in-house general laboratory procedures. Both the transferring and receiving units should compare and discuss data as well as any deviations from the protocol. This discussion addresses any necessary corrections or updates to the final report and the analytical procedure as necessary to reproduce the procedure.

A single lot of the article may be used for the transfer, because the aim of the transfer is not related to the manufacturing process but rather to the evaluation of the analytical procedure's performance at the receiving site.

PREAPPROVED PROTOCOL

A well-designed protocol should be discussed, agreed upon, and documented before the implementation of TAP. The document expresses a consensus between the parties, indicating an intended execution strategy, and should include each party's requirements and responsibilities. It is recommended that the protocol contain the following topics as appropriate: objective, scope, responsibilities of the transferring and receiving units, materials and instruments that will be used, analytical procedure, experimental design, and acceptance criteria for all tests and/or methods included in the transfer. Based on the validation data and procedural knowledge, the transfer protocol should identify the specific analytical performance characteristics (see <1225> and <1226>) that will be evaluated and the analysis that will be used to evaluate acceptable outcomes of the transfer exercise.

The transfer acceptance criteria, which are based on method performance and historical data from stability and release results, if available, should include the comparability criteria for results from all study sites. These criteria may be derived using statistical principles based on the difference between mean values and established ranges and should be accompanied by an estimation of the variability (e.g., percent relative standard deviation [%RSD] for each site), particularly for the intermediate precision %RSD of the receiving unit and/or a statistical method for the comparison of the means for assay and content uniformity tests. In instances of impurity testing, where precision may be poorer such as in the case of trace impurities, a simple descriptive approach can be used. Dissolution can be evaluated by a

comparison of the dissolution profiles using the similarity factor f_2 or by comparison of data at the specified time points. The laboratories should provide appropriate rationale for any analytical performance characteristic not included. The materials, reference standards, samples, instruments, and instrumental parameters that will be used should be described.

It is recommended that expired, aged, or spiked samples be carefully chosen and evaluated to identify potential problems related to differences in sample preparation equipment and to evaluate the impact of potential aberrant results on marketed products. The documentation section of the transfer protocol may include report forms to ensure consistent recording of results and to improve consistency between laboratories. This section should contain the additional information that will be included with the results, such as example chromatograms and spectra, along with additional information in case of a deviation. The protocol should also explain how any deviation from the acceptance criteria will be managed. Any changes to the transfer protocol following failure of an acceptance criterion must be approved before collection of additional data.

THE ANALYTICAL PROCEDURE

The procedure should be written with sufficient detail and explicit instructions, so that a trained analyst can perform it without difficulty. A pretransfer meeting between the transferring and receiving units is helpful to clarify any issues and answer any questions regarding the transfer process. If complete or partial validation data exist, they should be available to the receiving unit, along with any technical details required to perform the test in question. In some cases it may be useful for the individuals who were involved with the initial development or validation to be on site during the transfer. The number of replicates and injection sequences in the case of liquid or gas chromatography should be clearly expressed, and, in the case of dissolution testing, the number of individual dosage units should be stipulated.

TRANSFER REPORT

When the TAP is successfully completed, the receiving unit should prepare a transfer report that describes the results obtained in relation to the acceptance criteria, along with conclusions that confirm that the receiving unit is now qualified to run the procedure. Any deviations should be thoroughly documented and justified. If the acceptance criteria are met, the TAP is successful and the receiving unit is qualified to run the procedure. Otherwise, the procedure cannot be considered transferred until effective remedial steps are adopted in order to meet the acceptance criteria. An investigation may provide guidance about the nature and extent of the remedial steps, which may vary from further training and clarification to more complex approaches, depending on the particular procedure.

<1225> VALIDATION OF COMPENDIAL PROCEDURES

Test procedures for assessment of the quality levels of pharmaceutical articles are subject to various requirements. According to Section 501 of the Federal Food, Drug, and Cosmetic Act, assays and specifications in monographs of the United States Pharmacopeia and the National Formulary

constitute legal standards. The Current Good Manufacturing Practice regulations [21 CFR 211.194(a)] require that test methods, which are used for assessing compliance of pharmaceutical articles with established specifications, must meet proper standards of accuracy and reliability. Also, according to these regulations [21 CFR 211.194(a)(2)], users of analytical methods described in *USP–NF* are not required to validate the accuracy and reliability of these methods, but merely verify their suitability under actual conditions of use. Recognizing the legal status of *USP* and *NF* standards, it is essential, therefore, that proposals for adoption of new or revised compendial analytical procedures be supported by sufficient laboratory data to document their validity.

The text of this information chapter harmonizes, to the extent possible, with the Tripartite International Conference on Harmonization (ICH) documents *Validation of Analytical Procedures* and the *Methodology* extension text, which are concerned with analytical procedures included as part of registration applications submitted within the EC, Japan, and the USA.

SUBMISSIONS TO THE COMPENDIA

Submissions to the compendia for new or revised analytical procedures should contain sufficient information to enable members of the USP Council of Experts and its Expert Committees to evaluate the relative merit of proposed procedures. In most cases, evaluations involve assessment of the clarity and completeness of the description of the analytical procedures, determination of the need for the procedures, and documentation that they have been appropriately validated. Information may vary depending upon the type of method involved. However, in most cases a submission will consist of the following sections.

Rationale—This section should identify the need for the procedure and describe the capability of the specific procedure proposed and why it is preferred over other types of determinations. For revised procedures, a comparison should be provided of limitations of the current compendial procedure and advantages offered by the proposed procedure.

Proposed Analytical Procedure—This section should contain a complete description of the analytical procedure sufficiently detailed to enable persons “skilled in the art” to replicate it. The write-up should include all important operational parameters and specific instructions such as preparation of reagents, performance of system suitability tests, description of blanks used, precautions, and explicit formulas for calculation of test results.

Data Elements—This section should provide thorough and complete documentation of the validation of the analytical procedure. It should include summaries of experimental data and calculations substantiating each of the applicable analytical performance characteristics. These characteristics are described in the following section.

VALIDATION

Validation of an analytical procedure is the process by which it is established, by laboratory studies, that the performance characteristics of the procedure meet the requirements for the intended analytical applications. Typical analytical performance characteristics that should be considered in the validation of the types of procedures described in this document are listed in *Table 1*. Because opinions may differ with respect to terminology and use, each of the performance characteristics is defined in the next section of this chapter, along with a delineation of a typical method or methods by which it may be measured. The definitions refer to “test results.” The description of the analytical procedure should define what the test results for the procedure are. As noted in ISO 5725-1 and 3534-1, a test result is “the value

of a characteristic obtained by carrying out a specified test method. The test method should specify that one or a number of individual measurements be made, and their average, or another appropriate function (such as the median or the standard deviation), be reported as the test result. It may also require standard corrections to be applied, such as correction of gas volumes to standard temperature and pressure. Thus, a test result can be a result calculated from several observed values. In the simple case, the test result is the observed value itself.” A test result also can be, but need not be, the final, reportable value that would be compared to the acceptance criteria of a specification. Validation of physical property methods may involve the assessment of chemometric models. However, the typical analytical characteristics used in method validation can be applied to the methods derived from the use of the chemometric models.

Table 1. Typical Analytical Characteristics Used in Method Validation

Accuracy
Precision
Specificity
Detection Limit
Quantitation Limit
Linearity
Range
Robustness

The effects of processing conditions and potential for segregation of materials should be considered when obtaining a representative sample to be used for validation of procedures.

In the case of compendial procedures, revalidation may be necessary in the following cases: a submission to the USP of a revised analytical procedure; or the use of an established general procedure with a new product or raw material (see below in *Data Elements Required for Validation*).

The ICH documents give guidance on the necessity for revalidation in the following circumstances: changes in the synthesis of the drug substance; changes in the composition of the drug product; and changes in the analytical procedure.

Chapter (1225) is intended to provide information that is appropriate to validate a wide range of compendial analytical procedures. The validation of compendial procedures may use some or all of the suggested typical analytical characteristics used in method validation as outlined in *Table 1* and categorized by type of analytical method in *Table 2*. For some compendial procedures the fundamental principles of validation may extend beyond characteristics suggested in Chapter (1225). For these procedures the user is referred to the individual compendial chapter for those specific analytical validation characteristics and any specific validation requirements.

Analytical Performance Characteristics

ACCURACY

Definition—The accuracy of an analytical procedure is the closeness of test results obtained by that procedure to the true value. The accuracy of an analytical procedure should be established across its range. [A note on terminology: The definition of accuracy in (1225) and ICH Q2 corresponds to unbiasedness only. In the International Vocabulary of Metrology (VIM) and documents of the International Organization for Standardization (ISO), “accuracy” has a different meaning. In ISO, accuracy combines the concepts of unbiasedness (termed “trueness”) and precision.]

Determination—In the case of the assay of a drug substance, accuracy may be determined by application of the analytical procedure to an analyte of known purity (e.g., a Reference Standard) or by comparison of the results of the procedure with those of a second, well-characterized procedure, the accuracy of which has been stated or defined.

In the case of the assay of a drug in a formulated product, accuracy may be determined by application of the analytical procedure to synthetic mixtures of the drug product components to which known amounts of analyte have been added within the range of the procedure. If it is not possible to obtain samples of all drug product components, it may be acceptable either to add known quantities of the analyte to the drug product (i.e., “to spike”) or to compare results with those of a second, well-characterized procedure, the accuracy of which has been stated or defined.

In the case of quantitative analysis of impurities, accuracy should be assessed on samples (of drug substance or drug product) spiked with known amounts of impurities. Where it is not possible to obtain samples of certain impurities or degradation products, results should be compared with those obtained by an independent procedure. In the absence of other information, it may be necessary to calculate the amount of an impurity based on comparison of its response to that of the drug substance; the ratio of the responses of equal amounts of the impurity and the drug substance (relative response factor) should be used if known.

Accuracy is calculated as the percentage of recovery by the assay of the known added amount of analyte in the sample, or as the difference between the mean and the accepted true value, together with confidence intervals.

The ICH documents recommend that accuracy should be assessed using a minimum of nine determinations over a minimum of three concentration levels, covering the specified range (i.e., three concentrations and three replicates of each concentration).

Assessment of accuracy can be accomplished in a variety of ways, including evaluating the recovery of the analyte (percent recovery) across the range of the assay, or evaluating the linearity of the relationship between estimated and actual concentrations. The statistically preferred criterion is that the confidence interval for the slope be contained in an interval around 1.0, or alternatively, that the slope be close to 1.0. In either case, the interval or the definition of closeness should be specified in the validation protocol. The acceptance criterion will depend on the assay and its variability and on the product. Setting an acceptance criterion based on the lack of statistical significance of the test of the null hypothesis that the slope is 1.0 is not an acceptable approach.

Accuracy of physical property methods may be assessed through the analysis of standard reference materials, or alternatively, the suitability of the above approaches may be considered on a case-by-case basis.

PRECISION

Definition—The precision of an analytical procedure is the degree of agreement among individual test results when the procedure is applied repeatedly to multiple samplings of a homogeneous sample. The precision of an analytical procedure is usually expressed as the standard deviation or relative standard deviation (coefficient of variation) of a series of measurements. Precision may be a measure of either the degree of reproducibility or of repeatability of the analytical procedure under normal operating conditions. In this context, reproducibility refers to the use of the analytical procedure in different laboratories, as in a collaborative study. Intermediate precision (also known as ruggedness) expresses within-laboratory variation, as on different days, or with different analysts or equipment within the same laboratory. Repeatability refers to the use of the analytical procedure within a laboratory over a short period of time using the same analyst with the same equipment.

Determination—The precision of an analytical procedure is determined by assaying a sufficient number of aliquots of a homogeneous sample to be able to calculate statistically valid estimates of standard deviation or relative standard deviation (coefficient of variation). Assays in this context are independent analyses of samples that have been carried through the complete analytical procedure from sample preparation to final test result.

The ICH documents recommend that repeatability should be assessed using a minimum of nine determinations covering the specified range for the procedure (i.e., three concentrations and three replicates of each concentration) or using a minimum of six determinations at 100% of the test concentration.

SPECIFICITY

Definition—The ICH documents define specificity as the ability to assess unequivocally the analyte in the presence of components that may be expected to be present, such as impurities, degradation products, and matrix components. Lack of specificity of an individual analytical procedure may be compensated by other supporting analytical procedures. [NOTE—Other reputable international authorities (IUPAC, AOAC-I) have preferred the term “selectivity,” reserving “specificity” for those procedures that are completely selective.] For the tests discussed below, the above definition has the following implications:

Identification Tests: ensure the identity of the analyte.

Purity Tests: ensure that all the analytical procedures performed allow an accurate statement of the content of impurities of an analyte (e.g., related substances test, heavy metals limit, organic volatile impurities).

Assays: provide an exact result, which allows an accurate statement on the content or potency of the analyte in a sample.

Determination—In the case of qualitative analyses (identification tests), the ability to select between compounds of closely related structure that are likely to be present should be demonstrated. This should be confirmed by obtaining positive results (perhaps by comparison to a known reference material) from samples containing the analyte, coupled with negative results from samples that do not contain the analyte and by confirming that a positive response is not obtained from materials structurally similar to or closely related to the analyte.

In the case of analytical procedures for impurities, specificity may be established by spiking the drug substance or product with appropriate levels of impurities and demonstrating that these impurities are determined with appropriate accuracy and precision.

In the case of the assay, demonstration of specificity requires that it can be shown that the procedure is unaffected by the presence of impurities or excipients. In practice, this can be done by spiking the drug substance or product with appropriate levels of impurities or excipients and demonstrating that the assay result is unaffected by the presence of these extraneous materials.

If impurity or degradation product standards are unavailable, specificity may be demonstrated by comparing the test results of samples containing impurities or degradation products to a second well-characterized procedure (e.g., a Pharmacopeial or other validated procedure). These comparisons should include samples stored under relevant stress conditions (e.g., light, heat, humidity, acid/base hydrolysis, and oxidation). In the case of the assay, the results should be compared; in the case of chromatographic impurity tests, the impurity profiles should be compared.

The ICH documents state that when chromatographic procedures are used, representative chromatograms should be presented to demonstrate the degree of selectivity, and peaks should be appropriately labeled. Peak purity tests (e.g., using diode array or mass spectrometry) may be used.

ful to show that the analyte chromatographic peak is not attributable to more than one component.

For validation of specificity for qualitative and quantitative determinations by spectroscopic methods, chapters related to topics such as near-infrared spectrophotometry, raman spectroscopy, and X-ray powder diffraction should be consulted.

DETECTION LIMIT

Definition—The detection limit is a characteristic of limit tests. It is the lowest amount of analyte in a sample that can be detected, but not necessarily quantitated, under the stated experimental conditions. Thus, limit tests merely substantiate that the amount of analyte is above or below a certain level. The detection limit is usually expressed as the concentration of analyte (e.g., percentage, parts per billion) in the sample.

Determination—For noninstrumental procedures, the detection limit is generally determined by the analysis of samples with known concentrations of analyte and by establishing the minimum level at which the analyte can be reliably detected.

For instrumental procedures, the same approach may be used as for noninstrumental procedures. In the case of procedures submitted for consideration as official compendial procedures, it is almost never necessary to determine the actual detection limit. Rather, the detection limit is shown to be sufficiently low by the analysis of samples with known concentrations of analyte above and below the required detection level. For example, if it is required to detect an impurity at the level of 0.1%, it should be demonstrated that the procedure will reliably detect the impurity at that level.

In the case of instrumental analytical procedures that exhibit background noise, the ICH documents describe a common approach, which is to compare measured signals from samples with known low concentrations of analyte with those of blank samples. The minimum concentration at which the analyte can reliably be detected is established. Typically acceptable signal-to-noise ratios are 2:1 or 3:1. Other approaches depend on the determination of the slope of the calibration curve and the standard deviation of responses. Whatever method is used, the detection limit should be subsequently validated by the analysis of a suitable number of samples known to be near, or prepared at, the detection limit.

QUANTITATION LIMIT

Definition—The quantitation limit is a characteristic of quantitative assays for low levels of compounds in sample matrices, such as impurities in bulk drug substances and degradation products in finished pharmaceuticals. It is the lowest amount of analyte in a sample that can be determined with acceptable precision and accuracy under the stated experimental conditions. The quantitation limit is expressed as the concentration of analyte (e.g., percentage, parts per billion) in the sample.

Determination—For noninstrumental procedures, the quantitation limit is generally determined by the analysis of samples with known concentrations of analyte and by establishing the minimum level at which the analyte can be determined with acceptable accuracy and precision.

For instrumental procedures, the same approach may be used as for noninstrumental procedures. In the case of procedures submitted for consideration as official compendial procedures, it is almost never necessary to determine the actual quantitation limit. Rather, the quantitation limit is shown to be sufficiently low by the analysis of samples with known concentrations of analyte above and below the quantitation level. For example, if it is required that an analyte be assayed at the level of 0.1 mg per tablet, it

should be demonstrated that the procedure will reliably quantitate the analyte at that level.

In the case of instrumental analytical procedures that exhibit background noise, the ICH documents describe a common approach, which is to compare measured signals from samples with known low concentrations of analyte with those of blank samples. The minimum concentration at which the analyte can reliably be quantified is established. A typically acceptable signal-to-noise ratio is 10:1. Other approaches depend on the determination of the slope of the calibration curve and the standard deviation of responses. Whatever approach is used, the quantitation limit should be subsequently validated by the analysis of a suitable number of samples known to be near, or prepared at, the quantitation limit.

LINEARITY AND RANGE

Definition of Linearity—The linearity of an analytical procedure is its ability to elicit test results that are directly, or by a well-defined mathematical transformation, proportional to the concentration of analyte in samples within a given range. Thus, in this section, "linearity" refers to the linearity of the relationship of concentration and assay measurement. In some cases, to attain linearity, the concentration and/or the measurement may be transformed. (Note that the weighting factors used in the regression analysis may change when a transformation is applied.) Possible transformations may include log, square root, or reciprocal, although other transformations are acceptable. If linearity is not attainable, a nonlinear model may be used. The goal is to have a model, whether linear or nonlinear, that describes closely the concentration-response relationship.

Definition of Range—The range of an analytical procedure is the interval between the upper and lower levels of analyte (including these levels) that have been demonstrated to be determined with a suitable level of precision, accuracy, and linearity using the procedure as written. The range is normally expressed in the same units as test results (e.g., percent, parts per million) obtained by the analytical procedure.

Determination of Linearity and Range—Linearity should be established across the range of the analytical procedure. It should be established initially by visual examination of a plot of signals as a function of analyte concentration of content. If there appears to be a linear relationship, test results should be established by appropriate statistical methods (e.g., by calculation of a regression line by the method of least squares). Data from the regression line itself may be helpful to provide mathematical estimates of the degree of linearity. The correlation coefficient, y-intercept, slope of the regression line, and residual sum of squares should be submitted.

The range of the procedure is validated by verifying that the analytical procedure provides acceptable precision, accuracy, and linearity when applied to samples containing analyte at the extremes of the range as well as within the range.

ICH recommends that, for the establishment of linearity, a minimum of five concentrations normally be used. It is also recommended that the following minimum specified ranges should be considered:

Assay of a Drug Substance (or a finished product): from 80% to 120% of the test concentration.

Determination of an Impurity: from 50% to 120% of the acceptance criterion.

For Content Uniformity: a minimum of 70% to 130% of the test concentration, unless a wider or more appropriate range based on the nature of the dosage form (e.g., metered-dose inhalers) is justified.

For Dissolution Testing: $\pm 20\%$ over the specified range (e.g., if the acceptance criteria for a controlled-release prod-

uct cover a region from 30%, after 1 hour, and up to 90%, after 24 hours, the validated range would be 10% to 110% of the label claim).

The traditional definition of linearity, i.e., the establishment of a linear or mathematical relationship between sample concentration and response, is not applicable to particle size analysis. For particle size analysis, a concentration range is defined (instrument- and particle size-dependent) such that the measured particle size distribution is not affected by changes in concentration within the defined concentration range. Concentrations below the defined concentration range may introduce an error due to poor signal-to-noise ratio, and concentrations exceeding the defined concentration range may introduce an error due to multiple scattering.

ROBUSTNESS

Definition—The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in procedural parameters listed in the procedure documentation and provides an indication of its suitability during normal usage. Robustness may be determined during development of the analytical procedure.

SYSTEM SUITABILITY

If measurements are susceptible to variations in analytical conditions, these should be suitably controlled, or a precautionary statement should be included in the procedure. One consequence of the evaluation of robustness and ruggedness should be that a series of system suitability parameters is established to ensure that the validity of the analytical procedure is maintained whenever used. Typical variations are the stability of analytical solutions, different equipment, and different analysts. In the case of liquid chromatography, typical variations are the pH of the mobile phase, the mobile phase composition, different lots or suppliers of columns, the temperature, and the flow rate. In the case of gas chromatography, typical variations are different lots or suppliers of columns, the temperature, and the flow rate.

System suitability tests are based on the concept that the equipment, electronics, analytical operations, and samples to be analyzed constitute an integral system that can be evaluated as such. System suitability test parameters to be established for a particular procedure depend on the type of procedure being evaluated. They are especially important in the case of chromatographic procedures. Submissions to the USP should make note of the requirements under the *System Suitability* section in the general test chapter *Chromatography* (621).

Data Elements Required for Validation

Compendial test requirements vary from highly exacting analytical determinations to subjective evaluation of attrib-

utes. Considering this broad variety, it is only logical that different test procedures require different validation schemes. This chapter covers only the most common categories of tests for which validation data should be required. These categories are as follows:

Category I—Analytical procedures for quantitation of major components of bulk drug substances or active ingredients (including preservatives) in finished pharmaceutical products.

Category II—Analytical procedures for determination of impurities in bulk drug substances or degradation compounds in finished pharmaceutical products. These procedures include quantitative assays and limit tests.

Category III—Analytical procedures for determination of performance characteristics (e.g., dissolution, drug release, etc.).

Category IV—Identification tests.

For each category, different analytical information is needed. Listed in *Table 2* are data elements that are normally required for each of these categories.

Already established general procedures (e.g., titrimetric determination of water, bacterial endotoxins) should be verified to establish their suitability for use, such as their accuracy (and absence of possible interference) when used for a new product or raw material.

When validating physical property methods, consider the same performance characteristics required for any analytical procedure. Evaluate use of the performance characteristics on a case-by-case basis, with the goal of determining that the procedure is suitable for its intended use. The specific acceptance criteria for each validation parameter should be consistent with the intended use of the method.

Physical methods may also be classified into the four validation categories. For example, validation of a quantitative spectroscopic method may involve evaluation of *Category I* or *Category II Analytical Performance Characteristics*, depending on the method requirements. Qualitative physical property measurements, such as particle size, surface area, bulk and tapped density, which could impact performance characteristics, often best fit in *Category III*. *Category IV Analytical Performance Characteristics* usually applies to validation of qualitative identification spectroscopic methods. However, the various techniques may be used for different purposes, and the specific use of the method and characteristics of the material being analyzed should be considered when definitively applying a category to a particular type of method.

The validity of an analytical procedure can be verified only by laboratory studies. Therefore, documentation of the successful completion of such studies is a basic requirement for determining whether a procedure is suitable for its intended application(s). Current compendial procedures are also subject to regulations that require demonstration of suitability under actual conditions of use (see *Verification of Compendial Procedures* (1226) for principles relative to the verification of compendial procedures). Appropriate documentation should

Range	Yes	Yes	*	*	No

*May be required, depending on the nature of the specific test.

accompany any proposal for new or revised compendial analytical procedures.

<1226> VERIFICATION OF COMPENDIAL PROCEDURES

The intent of this general information chapter is to provide general information on the verification of compendial procedures that are being performed for the first time to yield acceptable results utilizing the personnel, equipment, and reagents available. This chapter is not intended for retroactive application to already successfully established laboratory procedures. The chapter *Validation of Compendial Procedures* (1225) provides general information on characteristics that should be considered for various test categories and on the documentation that should accompany analytical procedures submitted for inclusion in *USP–NF*. Verification consists of assessing selected analytical performance characteristics, such as those that are described in chapter <1225>, to generate appropriate, relevant data rather than repeating the validation process.

Users of compendial analytical procedures are not required to validate these procedures when first used in their laboratories, but documented evidence of suitability should be established under actual conditions of use. In the United States, this requirement is established in 21 CFR 211.194(a)(2) of the current Good Manufacturing Practice regulations, which states that the “suitability of all testing methods used shall be verified under actual conditions of use.”

Verification of microbiological procedures is not covered in this chapter because it is covered in USP general test chapters *Antimicrobial Effectiveness Testing* (51), *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* (61), *Microbiological Examination of Nonsterile Products: Tests for Specified Microorganisms* (62), *Sterility Tests* (71), and in general information chapter *Validation of Microbial Recovery from Pharmacopoeial Articles* (1227).

VERIFICATION PROCESS

The verification process for compendial test procedures is the assessment of whether the procedure can be used for its intended purpose, under the actual conditions of use for a specified drug substance and/or drug product matrix.

Users should have the appropriate experience, knowledge, and training to understand and be able to perform the compendial procedures as written. Verification should be conducted by the user such that the results will provide confidence that the compendial procedure will perform suitably as intended.

If the verification of the compendial procedure is not successful, and assistance from USP staff has not resolved the problem, it may be concluded that the procedure may not be suitable for use with the article being tested in that laboratory. It may then be necessary to develop and validate an alternate procedure as allowed in the *General Notices*. The alternate procedure may be submitted to USP, along with the appropriate data, to support a proposal for inclusion or replacement of the current compendial procedure.

VERIFICATION REQUIREMENTS

Verification requirements should be based on an assessment of the complexity of both the procedure and the material to which the procedure is applied. Although complete revalidation of a compendial method is not required to verify the suitability of a procedure under actual conditions of use, some of the analytical performance characteristics listed in chapter <1225>, *Table 2*, may be used for the verification process. Only those characteristics that are considered to be appropriate for the verification of the particular procedure need to be evaluated. The process of assessing the suitability of a compendial analytical test procedure under the conditions of actual use may or may not require actual laboratory performance of each analytical performance characteristic. The degree and extent of the verification process may depend on the level of training and experience of the user, on the type of procedure and its associated equipment or instrumentation, on the specific procedural steps, and on which article(s) are being tested.

Verification should assess whether the compendial procedure is suitable for the drug substance and/or the drug product matrix, taking into account the drug substance's synthetic route, the method of manufacture for the drug product, or both, if applicable. Verification should include an assessment of elements such as the effect of the matrix on the recovery of impurities and drug substances from the drug product matrix, as well as the suitability of chromatographic conditions and column, the appropriateness of detector signal response, etc.

As an example, an assessment of specificity is a key parameter in verifying that a compendial procedure is suitable for use in assaying drug substances and drug products. For instance, acceptable specificity for a chromatographic method may be verified by conformance with system suitability resolution requirements (if specified in the procedure). However, drug substances from different suppliers may have different impurity profiles that are not addressed by the compendial test procedure. Similarly, the excipients in a drug product can vary widely among manufacturers and may have the potential to directly interfere with the procedure or cause the formation of impurities that are not addressed by the compendial procedure. In addition, drug products containing different excipients, antioxidants, buffers, or container extractives may affect the recovery of the drug substance from the matrix. In these cases, a more thorough assessment of the matrix effects may be required to demonstrate suitability of the procedure for the particular drug substance or product. Other analytical performance characteristics such as an assessment of the limit of detection or quantitation and precision for impurities procedures may be useful to demonstrate the suitability of the compendial procedure under actual conditions of use.

Verification is not required for basic compendial test procedures that are routinely performed unless there is an indication that the compendial procedure is not appropriate for the article under test. Examples of basic compendial procedures include, but are not limited to, loss on drying, residue on ignition, various wet chemical procedures such as acid value, and simple instrumental determinations such as pH measurements. However, for the application of already established routine procedures to compendial articles tested for the first time, it is recommended that consideration be

given to any new or different sample handling or solution preparation requirements.

<1227> VALIDATION OF MICROBIAL RECOVERY FROM PHARMACOPeIAL ARTICLES

This chapter provides guidelines for the validation of methods for the estimation of the number of viable microorganisms, for the detection of indicators or objectionable microorganisms, for the validation of microbiological methods used in antimicrobial effectiveness testing, and for the sterility testing of Pharmacopeial articles. It is generally understood that if a product possesses antimicrobial properties because of the presence of a specific preservative or because of its formulation, this antimicrobial property must be neutralized to recover viable microorganisms. This neutralization may be achieved by the use of a specific neutralizer, by dilution, by a combination of washing and dilution, or by any combination of these methods.

The tests under *Antimicrobial Effectiveness Testing* <51>, *Sterility Tests* <71>, and *Microbial Enumeration Tests* <61> and *Tests for Specified Microorganisms* <62> require the validation of recovery methods. To ensure that the results of the tests are credible, neutralization of antimicrobial properties of the test solution is required before estimating the number of viable microorganisms.

INFLUENTIAL FACTORS

Several factors affect the measurement of a test solution's antimicrobial activity, and these must be considered in the validation design. They include the nature of the microorganisms used as challenge organisms, the preparation of the inoculum of challenge organisms, the specific conditions of the test, and the conditions of recovery. These factors also affect the validation of recovery methods for aqueous or nonaqueous products, irrespective of their antimicrobial properties; thus, all test methods should be validated with these factors in mind.

The nature of the challenge microorganism exerts a strong effect upon the response to the antimicrobial agent, and so upon the neutralization required for recovery. Represented among these organisms in compendial tests are Gram-positive bacteria, Gram-negative bacteria, yeasts, and molds. Each organism to be used in the test must be included in the validation.

The preparation of the inoculum of challenge microorganisms also affects the testing of products having antimicrobial

properties. The growth and preparation of the challenge organism determines the physiological state of the cell. This state has a direct influence on the results of any test of antimicrobial efficacy. Microbial tests do not use individual cells; rather, populations of cells are harvested for study. The data generated from these studies are less variable if the cell populations are homogeneous. Liquid cultures or confluent growths on solid medium are best suited for reproducible culture preparation. The conditions of organism preparation and storage must be standardized for the neutralizer evaluation and should reflect the conditions of the antimicrobial assay.

The specific conditions of the test, including buffers used, water, light conditions, and temperature, must be reproduced in the validation study. All test conditions also should be standardized and performed in the validation study exactly as performed in the test.

The conditions of microbial recovery are among the most crucial in accurately estimating the number of microorganisms present in a test solution. The first consideration is the recovery medium used to support the growth of survivors. This concern is discussed in detail below. The second consideration is the incubation conditions. Optimal conditions for growth must be present to ensure complete growth and reproducible results.

METHODS OF NEUTRALIZING ANTIMICROBIAL PROPERTIES

Three common methods are used to neutralize antimicrobial properties of a product: (1) chemical inhibition, (2) dilution, and (3) filtration and washing.

Chemical Inhibition

Table 1 shows known neutralizers for a variety of chemical antimicrobial agents and the reported toxicity of some chemical neutralizers to specific microorganisms. However, despite potential toxicity, the convenience and quick action of chemical inhibitors encourage their use. Chemical inhibition of bactericides is the preferred method for the antimicrobial efficacy test. The potential of chemical inhibitors should be considered in the membrane filtration and the direct transfer sterility tests. Antibiotics may not be susceptible to neutralization by chemical means, but rather by enzymatic treatment (e.g., penicillinase). These enzymes may be used where required.

Dilution

A second approach to neutralizing antimicrobial properties of a product is by dilution, because the concentration of a chemical bactericide exerts a large effect on its potency. The relationship between concentration and antimicrobial effect differs among bactericidal agents but is constant for a

Table 1. Some Common Neutralizers for Chemical Biocides

Neutralizer	Biocide Class	Potential Action of Biocides
Bisulfate	Glutaraldehyde, Mercurials	Non-Sporing Bacteria
Dilution	Phenolics, Alcohol, Aldehydes, Sorbate	—
Glycine	Aldehydes	Growing Cells
Lecithin	Quaternary Ammonium Compounds (QACs), Parabens, Bis-biquanides	Bacteria
Mg ⁺² or Ca ⁺² ions	EDTA	—
Polysorbate	QACS, Iodine, Parabens	—
Thioglycollate	Mercurials	Staphylococci and Spores
Thiosulfate	Mercurials, Halogens, Aldehydes	Staphylococci

particular antimicrobial agent. This relationship is exponential in nature, with the general formula:

$$C \cdot t = k$$

in which C is the concentration; t is the time required to kill a standard inoculum; k is a constant; and the concentration exponent, η , is the slope of the plot of $\log t$ versus $\log C$. Antimicrobial agents with high η values are rapidly neutralized by dilution, whereas those with low η values are not good candidates for neutralization by dilution.

Membrane Filtration

An approach that is often used, especially in sterility testing, is neutralization by membrane filtration. This approach relies upon the physical retention of the microorganism on the membrane filter, with the antimicrobial agent passing through the filter into the filtrate. The filter is then incubated for recovery of viable microorganisms. However, filtration alone may not remove sufficient quantities of the bactericidal agent to allow growth of surviving microorganisms. Adherence of residual antimicrobial agents to the filter membrane may cause growth inhibition. Filtration through a low-binding filter material, such as polyvinylidene difluoride, helps to minimize this growth inhibition. Additionally, the preservative may be diluted or flushed from the filter by rinsing with a benign fluid, such as diluting *Fluid A* (see *Diluting and Rinsing Fluids for Membrane Filtration* under *Sterility Tests* (71) for diluting fluid compositions). Chemical neutralizers in the rinsing fluid can ensure that any antimicrobial residue on the membrane does not interfere with the recovery of viable microorganisms.

VALIDATION OF NEUTRALIZATION METHODS—RECOVERY COMPARISONS

A validated method for neutralizing the antimicrobial properties of a product must meet two criteria: neutralizer efficacy and neutralizer toxicity. The validation study documents that the neutralization method employed is effective in inhibiting the antimicrobial properties of the product (neutralizer efficacy) without impairing the recovery of viable microorganisms (neutralizer toxicity). Validation protocols may meet these two criteria by comparing recovery results for treatment groups.

The first is the test group, in which the product is subjected to the neutralization method, then a low level of challenge microorganism [less than 100 colony-forming units (cfu)] is inoculated for recovery. The second is the peptone control group, in which the neutralization method is used with peptone, or diluting *Fluid A* (see *Sterility Tests* (71)), as the test solution. The third is the viability group, in which the actual inoculum is used without exposure to the neutralization scheme. Similar recovery between the test group and the peptone group demonstrates adequate neutralizer efficacy; similar recovery between the peptone group and the viability group demonstrates adequate neutralizer toxicity.

In principle, the protocol must show that recovery of a low inoculum (less than 100 cfu) is not inhibited by the test sample and the neutralization method. Validation protocols may meet these two criteria by comparing recovery among three distinct test groups: (1) neutralized product with inoculum, (2) challenge inoculum control in buffered solution, and (3) inoculum in the absence of product or neutralizer. This can be established by directly comparing the result in the treated solution (1) to the inoculum (3) above. If the growth on the treated solution is not comparable to the growth on the inoculum group, it should be determined whether the neutralization method itself is toxic to the microorganisms.

Recovery on Agar Medium

In the tests under *Antimicrobial Effectiveness Testing* (51) and *Microbial Enumeration Tests* (61) and *Tests for Specified Microorganisms* (62), the number of viable challenge microorganisms in the product is estimated at various time intervals by calculating the concentration of cfu per mL by the plate count method. A design for validating neutralization would incorporate the treatment groups as described under *Validation of Neutralization Methods—Recovery Comparisons*. At least three independent replicates of the experiment should be performed, and each should demonstrate that the average number of cfu recovered from the challenge product is not less than 70% of that recovered from the inoculum control.

If a greater number of replicates is required in the validation study, the comparisons may be evaluated by transforming the numbers of cfu to their logarithmic values and analyzing the data statistically by the Student t test (pairwise comparisons) or by analysis of variance (ANOVA) (for comparing all groups). If ANOVA is used, and significant differences among the populations are determined, a test such as Dunnett's test may be used, with the peptone group used as the control group.

Recovery by Membrane Filtration

This validation follows the procedure described for *Validation Test* under *Sterility Tests* (71), with the exception of plating on solid medium to quantitate recovery. Three 100-mL rinses are assumed, but the volume and number of rinses are subject to validation. Each validation run should be performed independently at least three times.

In the test solution group, the product is filtered through the membrane filter, followed by two 100-mL portions of diluting-neutralizing fluid. After the second rinse has been filtered, a final 100-mL portion containing less than 100 cfu of the specific challenge microorganism is passed through the filter. This filter is then placed on the appropriate agar recovery medium and incubated for recovery.

The inoculum is directly plated onto the solid medium. It is possible that filtration will lead to reduced recovery of the challenge microorganism, either through inherent toxicity of the membrane or by adherence of the microorganism to the filtration vessel walls. A control group can be used to evaluate this component of membrane filtration validation. Diluting *Fluid A* is used as the dilution medium without exposing the filter to the product. After addition of the low-level inoculum to the final rinse, the filter is plated as above. Technique-specific loss of microorganisms can be estimated by comparing the recovery in the diluting *Fluid A* group to the inoculum count.

It is assumed in this discussion that the test sample can be filtered. If it is necessary to solubilize the test sample, the effects of the solubilization method on viable microorganisms must be determined. This situation can occur when testing ointments, suspensions, or other articles.

The method can be considered validated if the recovery rate in the three independent replicates is similar for the test solution and the diluting *Fluid A* control.

Recovery in Liquid Medium

It is assumed in *Direct Inoculation of the Culture Medium* in the section *Test for Sterility of the Product to be Examined* under *Sterility Tests* (71) that the recovery medium will allow for growth of all surviving microorganisms. The broth in that test must serve both to neutralize any antimicrobial properties of the test solution and to support the growth of the microorganisms. The treatment groups described under *Validation of Neutralization Methods—Recovery Comparisons* above can be used for validation of the recovery method,

with the proportions of product and recovery medium varied to achieve adequate neutralization. The method can be considered validated if all groups show copious growth within 7 days for all microorganisms.

RECOVERY OF INJURED MICROORGANISMS

The validation studies described above use challenge microorganisms that have never been exposed to antimicrobial agents, and thus are not identical to organisms seen in antimicrobial effectiveness testing or when a sterility test is performed on a preserved product. If the use of alternative media is desired, the recovery of injured microorganisms should be addressed in the validation study. This may be done by directly comparing the recovery of each challenge microorganism on the preferred medium and on the alternative medium, after exposure to the product. This exposure should include at least two time periods showing survival of less than 100 cfu per mL, unless the rate of kill of the antimicrobial agent is such that no recovery is possible even if the microorganism is plated within minutes of exposure. This comparison should be performed at least three times. The alternative medium is validated if the recovery seen on that medium is no less than that seen on the preferred medium, within an error of 0.5 log units.

ESTIMATING THE NUMBER OF COLONY-FORMING UNITS

The accuracy of any estimate of viable cfu is affected by the number plated. As the number of viable cells plated increases, crowding effects decrease the accuracy of the count, reducing the estimate. As the number decreases, random error plays an increasing role in the estimate.

The accepted range for countable colonies on a standard agar plate is between 25 and 250 for most bacteria and *Candida albicans*. This range was established in the food industry for counting coliform bacteria in milk. This range is acceptable for compendial organisms, except for fungi. It is not optimal for counting all environmental isolates. The recommended counting range for *Aspergillus niger* is between 8 and 80 cfu per plate. The use of membrane filtration to recover challenge microorganisms, or the use of environmental isolates as challenge microorganisms in antimicrobial effectiveness testing, requires validation of the countable range. This validation may be performed by statistical comparison of estimated cfu from successive pairs in a dilution series. Prepare a suspension so that plating will provide approximately 1000 cfu per plate, and then dilute twofold to a theoretical concentration of approximately 1 cfu per plate. Plate all dilutions in the series in duplicate, and incubate for recovery under the conditions of the *Antimicrobial Effectiveness Testing* 〈51〉. Compare the estimates of cfu per mL from paired tubes in the dilution series by the formula:

$$\frac{|2L_{cfu} - H_{cfu}|}{\sqrt{2L_{cfu} + H_{cfu}}} \leq 1.96$$

in which L_{cfu} is the number of colonies on the plate with the lower count (greater dilution), and H_{cfu} is the number of colonies on the plate with the higher count (lesser dilution). The estimates of the cfu per mL provided by L_{cfu} and H_{cfu} should agree within the limits of the formula with a critical value of 1.96. The upper limit of plate counts is then defined as the number (H_{cfu}) that reproducibly passes this test. This study should be independently repeated a sufficient number of times to establish an upper limit of cfu for the particular plating conditions.

There is a lower limit at which the ability of the antimicrobial effectiveness test to recover microorganisms becomes untenable. If the first plating is performed with 1 mL of a 10^{-1} dilution, cfu in the range of 1 to 10 per mL would not

be seen. On this dilution plating, only the lower number of cfu may be reduced to 3, allowing as few survivors as 30 cfu per mL to be reported.

Lower counting thresholds for the greatest dilution plating in series must be justified. Numbers of colonies on a plate follow the Poisson distribution, so the variance of the mean value equals the mean value of counts. Therefore, as the mean number of cfu per plate becomes lower, the percentage error of the estimate increases (see Table 2). Three cfu per plate at the 10^{-1} dilution provide an estimate of 30 cfu per mL, with an error of 58% of the estimate.

〈1230〉 WATER FOR HEMODIALYSIS APPLICATIONS

GENERAL PURIFICATION CONSIDERATIONS

Chemical and microbial components that can be found in drinking water meeting U.S. Environmental Protection Agency National Primary Drinking Water Regulations (or equivalent) may have the potential to produce significant negative effects in patients undergoing hemodialysis. It is, therefore, necessary to subject the water to further treatment to reduce these components to acceptable levels. The

Water for Hemodialysis monograph provides bacterial and chemical tests that are required to ensure patient safety. Additional testing is recommended as follows:

- (1) Excess levels of aluminum, fluorides, and chlorine may be found seasonally in drinking water as a result of chemicals used in water treatment. These components should be monitored in Water for Hemodialysis being produced in accordance with established standard operating procedures. The maximum acceptable levels of these and other elements and compounds, as proposed by AAMI (Association for the Advancement of Medical Instrumentation) are listed in Table 1. These attributes should be periodically monitored to ensure they are being controlled by the routine testing performed in accordance with the Water for Hemodialysis monograph.
- (2) A comprehensive validation testing of the system producing Water for Hemodialysis should be performed initially and periodically thereafter to ensure that the water treatment equipment and system sanitization processes are functioning properly.

Table 1. Maximum Allowable Chemical Levels in Water for Hemodialysis	
(water used to prepare dialysate and concentrates from powder at a dialysis facility and to reprocess dialyzers for multiple use)*

The chemical limits included in Table 1 have been recognized by federal government agencies as standards for Water for Hemodialysis. Written standard operating procedures for water testing should be established by the physician in charge or the designated facility manager. The test frequency decision should be based upon historical data analysis, the quality of the source water as reported by the

municipal water treatment facility or public health agency in the area, etc. Records should be maintained to document levels and any necessary remedial action taken promptly.

Chemical analysis of water components listed should be performed using methods referenced in the American Public Health Association's *Standard Methods for the Examination of Water and Wastewater*, 21st Edition,¹ those referenced in the U.S. Environmental Protection Agency's *Methods for the Determination of Metals in Environmental Samples*,² or equivalent methods as referenced in ANSI/AAMI RD 62:2006.

MICROBIAL CONSIDERATIONS

The Water for Hemodialysis monograph includes total aerobic microbial count (TAMC) limits of 100 cfu/mL and endotoxin limits of 1 USP Endotoxin Unit/mL. In addition, the absence of *Pseudomonas aeruginosa* should be routinely determined because this is an opportunistic pathogen hazardous to acutely ill hemodialysis patients. Both the high microbial counts and the presence of *Pseudomonas aeruginosa* can be associated with inadequate water system maintenance and sanitization. Sampling the water should be done at all use points where the water enters the dialysis equipment. Samples should be assayed within 30 minutes of collection or immediately refrigerated and then assayed within 24 hours of collection. The microbial enumeration and absence tests are performed using procedures found in the USP general test chapters *Microbial Enumeration Tests* (61) and *Tests for Specified Microorganisms* (62). Quantification of bacterial endotoxins is performed using procedures found in the USP general test chapter *Bacterial Endotoxins Test* (85).

Because of the incubation time required to obtain definitive microbiological results, water systems should be microbiologically monitored to confirm that they continue to produce water of acceptable quality. "Alert" and "Action Levels" are therefore necessary for the monitoring and control of the system. An Alert Level constitutes a warning and does not require a corrective action. An Action Level indicates a drift from normal operating conditions and requires that corrective action be taken to bring the process back into the normal operating range. Exceeding an Alert or Action Level does not imply that water quality has been compromised. The maximum recommended Action Level for a total viable microbial count in the product water should be no greater than 25 cfu/mL, and the maximum recommended Action Level for bacterial endotoxins should be no greater than 0.25 USP Endotoxin Unit/mL. As with all process control values, Action and Alert Levels should be established from normal system monitoring trends and process capabilities in a fashion that allows remedial actions to occur in response to process control level excursions well before specifications are exceeded (also see *Microbial Considerations* under Water for Pharmaceutical Purposes (1231)).

(1231) WATER FOR PHARMACEUTICAL PURPOSES

INTRODUCTION

Water is widely used as a raw material, ingredient, and solvent in the processing, formulation, and manufacture of

¹ American Public Health Association, Washington, DC 20005.
² U.S. Environmental Protection Agency Publication EPA-600-R-94-111, Cincinnati, OH.

pharmaceutical products, active pharmaceutical ingredients (APIs) and intermediates, compendial articles, and analytical reagents. This general information chapter provides additional information about water, its quality attributes that are not included within a water monograph, processing techniques that can be used to improve water quality, and a description of minimum water quality standards that should be considered when selecting a water source.

This information chapter is not intended to replace existing regulations or guides that already exist to cover USA and International (ICH or WHO) GMP issues, engineering guides, or other regulatory (FDA, EPA, or WHO) guidances for water. The contents will help users to better understand pharmaceutical water issues and some of the microbiological and chemical concerns unique to water. This chapter is not an all-inclusive writing on pharmaceutical waters. It contains points that are basic information to be considered, when appropriate, for the processing, holding, and use of water. It is the user's responsibility to assure that pharmaceutical water and its production meet applicable governmental regulations, guidances, and the compendial specifications for the types of water used in compendial articles.

Control of the chemical purity of these waters is important and is the main purpose of the monographs in this compendium. Unlike other official articles, the bulk water monographs (*Purified Water* and *Water for Injection*) also limit how the article can be produced because of the belief that the nature and robustness of the purification process is directly related to the resulting purity. The chemical attributes listed in these monographs should be considered as a set of minimum specifications. More stringent specifications may be needed for some applications to ensure suitability for particular uses. Basic guidance on the appropriate applications of these waters is found in the monographs and is further explained in this chapter.

Control of the microbiological quality of water is important for many of its uses. Most packaged forms of water that have monograph standards are required to be sterile because some of their intended uses require this attribute for health and safety reasons. USP has determined that a microbial specification for the bulk monographed waters is inappropriate, and it has not been included within the monographs for these waters. These waters can be used in a variety of applications, some requiring extreme microbiological control and others requiring none. The needed microbial specification for a given bulk water depends upon its use. A single specification for this difficult-to-control attribute would unnecessarily burden some water users with irrelevant specifications and testing. However, some applications may require even more careful microbial control to avoid the proliferation of microorganisms ubiquitous to water during the purification, storage, and distribution of this substance. A microbial specification would also be inappropriate when related to the "utility" or continuous supply nature of this raw material. Microbial specifications are typically assessed by test methods that take at least 48 to 72 hours to generate results. Because pharmaceutical waters are generally produced by continuous processes and used in products and manufacturing processes soon after generation, the water is likely to have been used well before definitive test results are available. Failure to meet a compendial specification would require investigating the impact and making a pass/fail decision on all product lots between the previous sampling's acceptable test result and a subsequent sampling's acceptable test result. The technical and logistical problems created by a delay in the result of such an analysis do not eliminate the user's need for microbial specifications. Therefore, such water systems need to be operated and maintained in a controlled manner that requires that the system be validated to provide assurance of operational stability and that its microbial attributes be quantitatively monitored against established alert and action levels that would provide an early indication of system control. The issues of water system validation and alert/action levels and specifications are included in this chapter.

SOURCE OR FEED WATER CONSIDERATIONS

To ensure adherence to certain minimal chemical and microbiological quality standards, water used in the production of drug substances or as source or feed water for the preparation of the various types of purified waters must meet the requirements of the National Primary Drinking Water Regulations (NPDWR) (40 CFR 141) issued by the U.S. Environmental Protection Agency (EPA) or the drinking water regulations of the European Union or Japan, or the WHO drinking water guidelines. Limits on the types and quantities of certain organic and inorganic contaminants ensure that the water will contain only small, safe quantities of potentially objectionable chemical species. Therefore, water pretreatment systems will only be challenged to remove small quantities of these potentially difficult-to-remove chemicals. Also, control of objectionable chemical contaminants at the source-water stage eliminates the need to specifically test for some of them (e.g., trihalomethanes and heavy metals) after the water has been further purified.

Microbiological requirements of drinking water ensure the absence of coliforms, which, if determined to be of fecal origin, may indicate the potential presence of other potentially pathogenic microorganisms and viruses of fecal origin. Meeting these microbiological requirements does not rule out the presence of other microorganisms, which could be considered undesirable if found in a drug substance or formulated product.

To accomplish microbial control, municipal water authorities add disinfectants to drinking water. Chlorine-containing and other oxidizing substances have been used for many decades for this purpose and have generally been considered to be relatively innocuous to humans. However, these oxidants can interact with naturally occurring organic matter to produce disinfection by-products (DBPs), such as trihalomethanes (THMs, including chloroform, bromodichloromethane, and dibromochloromethane) and haloacetic acids (HAAs, including dichloroacetic acid and trichloroacetic acid). The levels of DBPs produced vary with the level and type of disinfectant used and the levels and types of organic materials found in the water, which can vary seasonally.

Because high levels of DBPs are considered a health hazard in drinking water, drinking water regulations mandate their control to generally accepted nonhazardous levels. However, depending on the unit operations used for further water purification, a small fraction of the DBPs in the starting water may carry over to the finished water. Therefore, the importance of having minimal levels of DBPs in the starting water, while achieving effective disinfection, is important.

DBP levels in drinking water can be minimized by using disinfectants such as ozone, chloramines, or chlorine dioxide. Like chlorine, their oxidative properties are sufficient to damage some pretreatment unit operations and must be removed early in the pretreatment process. The complete removal of some of these disinfectants can be problematic. For example, chloramines may degrade during the disinfection process or during pretreatment removal, thereby releasing ammonia, which in turn can carry over to the finished water. Pretreatment unit operations must be designed and operated to adequately remove the disinfectant, drinking water DBPs, and objectionable disinfectant degradants. A serious problem can occur if unit operations designed to remove chlorine were, without warning, challenged with chloramine-containing drinking water from a municipality that had been mandated to cease use of chlorine disinfection to comply with ever tightening EPA Drinking Water THM specifications. The dechlorination process might incompletely remove the chloramine, which could irreparably damage downstream unit operations, but also the release of ammonia during this process might carry through pretreatment and prevent the finished water from passing compendial conductivity specifications. The purification process must be

reassessed if the drinking water disinfectant is changed, emphasizing the need for a good working relationship between the pharmaceutical water manufacturer and the drinking water provider.

TYPES OF WATER

There are many different grades of water used for pharmaceutical purposes. Several are described in *USP* monographs that specify uses, acceptable methods of preparation, and quality attributes. These waters can be divided into two general types: bulk waters, which are typically produced on site where they are used; and sterile waters, which are produced, packaged, and sterilized to preserve microbial quality throughout their packaged shelf life. There are several specialized types of sterile waters, differing in their designated applications, packaging limitations, and other quality attributes.

There are also other types of water for which there are no monographs. These are all bulk waters, with names given for descriptive purposes only. Many of these waters are used in specific analytical methods. The associated text may not specify or imply certain quality attributes or modes of preparation. These nonmonographed waters may not necessarily adhere strictly to the stated or implied modes of preparation or attributes. Waters produced by other means or controlled by other test attributes may equally satisfy the intended uses for these waters. It is the user's responsibility to ensure that such waters, even if produced and controlled exactly as stated, be suitable for their intended use. Wherever the term "water" is used within these compendia without other descriptive adjectives or clauses, the intent is that water of no less purity than *Purified Water* be used.

What follows is a brief description of the various types of pharmaceutical waters and their significant uses or attributes. *Figure 1* may also be helpful in understanding some of the various types of waters.

Bulk Monographed Waters and Steam

The following waters are typically produced in large volume by a multiple-unit operation water system and distributed by a piping system for use at the same site. These particular pharmaceutical waters must meet the quality attributes as specified in the related monographs.

Purified Water—*Purified Water* (see the *USP* monograph) is used as an excipient in the production of nonparenteral preparations and in other pharmaceutical applications, such as cleaning of certain equipment and nonparenteral product-contact components. Unless otherwise specified, *Purified Water* is also to be used for all tests and assays for which water is indicated (see *General Notices and Requirements*). *Purified Water* is also referenced throughout the *USP-NF*. Regardless of the font and letter case used in its spelling, water complying with the *Purified Water* monograph is intended. *Purified Water* must meet the requirements for ionic and organic chemical purity and must be protected from microbial contamination. The minimal quality of source or feed water for the production of *Purified Water* is *Drinking Water*. This source water may be purified using unit operations that include deionization, distillation, ion exchange, reverse osmosis, filtration, or other suitable purification procedures. Purified water systems must be validated to reliably and consistently produce and distribute water of acceptable chemical and microbiological quality. Purified water systems that function under ambient conditions are particularly susceptible to the establishment of tenacious biofilms of microorganisms, which can be the source of undesirable levels of viable microorganisms or endotoxins in the effluent water. These systems require frequent sanitization and microbiological monitoring to ensure water of appropriate microbiological quality at the points of use.

The *Purified Water* monograph also allows bulk packaging for commercial use elsewhere. In contrast to *Sterile Purified Water*, bulk packaged *Purified Water* is not required to be sterile. Because there is potential for microbial contamination and other quality changes in this bulk packaged non-sterile water, this form of *Purified Water* should be prepared and stored in a fashion that limits microbial growth and/or is simply used in a timely fashion before microbial proliferation renders it unsuitable for its intended use. Also depending on the material used for packaging, there could be extractable compounds leaching into the water from the packaging. Though this article is required to meet the same chemical purity limits as the bulk water, packaging extractables will render the packaged water less pure than the bulk water. The nature of these impurities may even render the water an inappropriate choice for some applications. It is the user's responsibility to ensure fitness for use of this packaged article when used in manufacturing, clinical, or analytical applications where the pure bulk form of the water is indicated.

Water for Injection—*Water for Injection* (see the *USP* monograph) is used as an excipient in the production of parenteral and other preparations where product endotoxin content must be controlled, and in other pharmaceutical applications, such as cleaning of certain equipment and parenteral product-contact components. The minimum quality of source or feed water for the generation of *Water for Injection* is *Drinking Water* as defined by the U.S. Environmental Protection Agency (EPA), EU, Japan, or WHO. This source water may be pretreated to render it suitable for subsequent distillation (or whatever other validated process is used according to the monograph). The finished water must meet all of the chemical requirements for *Purified Water* as well as an additional bacterial endotoxin specification. Because endotoxins are produced by the kinds of microorganisms that are prone to inhabit water, the equipment and procedures used by the system to purify, store, and distribute *Water for Injection* must be designed to minimize or prevent microbial contamination as well as remove incoming endotoxins from the starting water. *Water for Injection* systems must be validated to reliably and consistently produce and distribute this quality of water.

The *Water for Injection* monograph also allows bulk packaging for commercial use. In contrast to *Sterile Water for Injection*, bulk packaged *Water for Injection* is not required to be sterile. However, to preclude significant changes in its microbial and endotoxins content during storage, this form of *Water for Injection* should be prepared and stored in a fashion that limits microbial growth and/or is simply used in a timely fashion before microbial proliferation renders it unsuitable for its intended use. Also depending on the material used for packaging, there could be extractable compounds leaching into the water from the packaging. Though this article is required to meet the same chemical purity limits as the bulk water, packaging extractables will render the packaged water less pure than the bulk water. The nature of these impurities may even render the water an inappropriate choice for some applications. It is the user's responsibility to ensure fitness for use of this packaged article when used in manufacturing, clinical, or analytical applications where the purer bulk form of the water is indicated.

Water for Hemodialysis—*Water for Hemodialysis* (see the *USP* monograph) is used for hemodialysis applications, primarily the dilution of hemodialysis concentrate solutions. It is produced and used on site and is made from EPA *Drinking Water* that has been further purified to reduce chemical and microbiological components. It may be packaged and stored in unreactive containers that preclude bacterial entry. The term "unreactive containers" implies that the container, especially its water contact surfaces, is not changed in any way by the water, such as by leaching of container-related compounds into the water or by any chemical reaction or corrosion caused by the water. The water contains no added antimicrobials and is not intended for injection. Its

Figure 1. Water for pharmaceutical purposes.

attributes include specifications for *Water conductivity*, *Total organic carbon* (or oxidizable substances), *Microbial limits*, and *Bacterial endotoxins*. The *Water conductivity* and *Total organic carbon* attributes are identical to those established for *Purified Water* and *Water for Injection*; however, instead of total organic carbon, the organic content may alternatively be measured by the test for *Oxidizable substances*. The *Microbial limits* attribute for this water is unique among the "bulk" water monographs, but is justified on the basis of this water's specific application that has microbial content requirements related to its safe use. The *Bacterial endotoxins* attribute is likewise established at a level related to its safe use.

Pure Steam—*Pure Steam* (see the USP monograph) is also sometimes referred to as "clean steam". It is used where the steam or its condensate would directly contact official articles or article-contact surfaces, such as during their preparation, sterilization, or cleaning where no subse-

quent processing step is used to remove any codeposited impurity residues. These *Pure Steam* applications include but are not limited to porous load sterilization processes, product or cleaning solutions heated by direct steam injection, or humidification of processes where steam injection is used to control the humidity inside processing vessels where the official articles or their in-process forms are exposed. The primary intent of using this quality of steam is to ensure that official articles or article-contact surfaces exposed to it are not contaminated by residues within the steam.

Pure Steam is prepared from suitably pretreated source water analogously to either the pretreatment used for *Purified Water* or *Water for Injection*. The water is vaporized with suitable mist elimination, and distributed under pressure. The sources of undesirable contaminants within *Pure Steam* could arise from entrained source water droplets, anticorrosion steam additives, or residues from the steam production and distribution system itself. The attributes in the *Pure*

Steam monograph should detect most of the contaminants that could arise from these sources. If the official article exposed to potential *Pure Steam* residues is intended for parenteral use or other applications where the pyrogenic content must be controlled, the *Pure Steam* must additionally meet the specification for *Bacterial Endotoxins* (85).

These purity attributes are measured on the condensate of the article, rather than the article itself. This, of course, imparts great importance to the cleanliness of the *Pure Steam* condensate generation and collection process because it must not adversely impact the quality of the resulting condensed fluid.

Other steam attributes not detailed in the monograph, in particular, the presence of even small quantities of noncondensable gases or the existence of a superheated or dry state, may also be important for applications such as sterilization. The large release of energy (latent heat of condensation) as water changes from the gaseous to the liquid state is the key to steam's sterilization efficacy and its efficiency, in general, as a heat transfer agent. If this phase change (condensation) is not allowed to happen because the steam is extremely hot and in a persistent superheated, dry state, then its usefulness could be seriously compromised. Noncondensable gases in steam tend to stratify or collect in certain areas of a steam sterilization chamber or its load. These surfaces would thereby be at least partially insulated from the steam condensation phenomenon, preventing them from experiencing the full energy of the sterilizing conditions. Therefore, control of these kinds of steam attributes, in addition to its chemical purity, may also be important for certain *Pure Steam* applications. However, because these additional attributes are use-specific, they are not mentioned in the *Pure Steam* monograph.

Note that less pure "plant steam" may be used for steam sterilization of nonproduct contact nonporous loads, for general cleaning of nonproduct contact equipment, as a nonproduct contact heat exchange medium, and in all compatible applications involved in bulk pharmaceutical chemical and API manufacture.

Finally, owing to the lethal properties of *Pure Steam*, monitoring of microbial control within a steam system is unnecessary. Therefore, microbial analysis of the steam condensate is unnecessary.

Sterile Monographed Waters

The following monographed waters are packaged forms of either *Purified Water* or *Water for Injection* that have been sterilized to preserve their microbiological properties. These waters may have specific intended uses as indicated by their names and may also have restrictions on packaging configurations related to those uses. In general, these sterile packaged waters may be used in a variety of applications in lieu of the bulk forms of water from which they were derived. However, there is a marked contrast between the quality tests and purities for these bulk versus sterile packaged waters. These quality tests and specifications for sterile packaged waters have diverged from those of bulk waters to accommodate a wide variety of packaging types, properties, volumes, and uses. As a result, the inorganic and organic impurity specifications and levels of the bulk and sterile packaged forms of water are not equivalent as their name similarities imply. The packaging materials and elastomeric closures are the primary sources of these impurities, which tend to increase over these packaged articles' shelf lives. Therefore, due consideration must be given to the chemical purity suitability at the time of use of the sterile packaged forms of water when used in manufacturing, analytical, and cleaning applications in lieu of the bulk waters from which these waters were derived. It is the user's responsibility to ensure fitness for use of these sterile packaged waters in these applications. Nevertheless, for the applications discussed below for each sterile packaged water, their respec-

tive purities and packaging restrictions generally render them suitable by definition.

Sterile Purified Water—*Sterile Purified Water* (see the *USP* monograph) is *Purified Water*, packaged and rendered sterile. It is used in the preparation of nonparenteral compendial dosage forms or in analytical applications requiring *Purified Water* where access to a validated *Purified Water* system is not practical, where only a relatively small quantity is needed, where *Sterile Purified Water* is required, or where bulk packaged *Purified Water* is not suitably microbiologically controlled.

Sterile Water for Injection—*Sterile Water for Injection* (see the *USP* monograph) is *Water for Injection* packaged and rendered sterile. It is used for extemporaneous prescription compounding and as a sterile diluent for parenteral products. It may also be used for other applications where bulk *Water for Injection* or *Purified Water* is indicated but where access to a validated water system is either not practical or where only a relatively small quantity is needed. *Sterile Water for Injection* is packaged in single-dose containers not larger than 1 L in size.

Bacteriostatic Water for Injection—*Bacteriostatic Water for Injection* (see the *USP* monograph) is sterile *Water for Injection* to which has been added one or more suitable antimicrobial preservatives. It is intended to be used as a diluent in the preparation of parenteral products, most typically for multi-dose products that require repeated content withdrawals. It may be packaged in single-dose or multiple-dose containers not larger than 30 mL.

Sterile Water for Irrigation—*Sterile Water for Irrigation* (see the *USP* monograph) is *Water for Injection* packaged and sterilized in single-dose containers of larger than 1 L in size that allows rapid delivery of its contents. It need not meet the requirement under small-volume injections in the general test chapter *Particulate Matter in Injections* (788). It may also be used in other applications that do not have particulate matter specifications, where bulk *Water for Injection* or *Purified Water* is indicated but where access to a validated water system is not practical, or where somewhat larger quantities than are provided as *Sterile Water for Injection* are needed.

Sterile Water for Inhalation—*Sterile Water for Inhalation* (see the *USP* monograph) is *Water for Injection* that is packaged and rendered sterile and is intended for use in inhalators and in the preparation of inhalation solutions. It carries a less stringent specification for bacterial endotoxins than *Sterile Water for Injection* and therefore is not suitable for parenteral applications.

Nonmonographed Manufacturing Waters

In addition to the bulk monographed waters described above, nonmonographed waters can also be used in pharmaceutical processing steps such as cleaning, synthetic steps, or a starting material for further purification. The following is a description of several of these nonmonographed waters as cited in various locations within these compendia.

Drinking Water—This type of water can be referred to as Potable Water (meaning drinkable or fit to drink), National Primary Drinking Water, Primary Drinking Water, or National Drinking Water. Except where a singular drinking water specification is stated (such as the NPDWR [U.S. Environmental Protection Agency's National Primary Drinking Water Regulations as cited in 40 CFR Part 141]), this water must comply with the quality attributes of either the NPDWR, or the drinking water regulations of the European Union or Japan, or the WHO Drinking Water Guidelines. It may be derived from a variety of sources including a public water utility, a private water supply (e.g., a well), or a combination of these sources. *Drinking Water* may be used in the early stages of cleaning pharmaceutical manufacturing equipment and product-contact components. *Drinking Water* is also the minimum quality of water that should be

* Drinking water is water complying with US EPA NPDRW or drinking water regulations of EU or Japan or WHO drinking water guidelines.

** Water for sterile APIs or dosage forms must first be rendered sterile if there is not a subsequent sterilization step in the process where used.

*** See guidance in this chapter where waters other than purified water are required by some USP tests and assays.

Note: All water systems should be validated with whatever microbial control is needed to suit the intended purposes of the water.

Figure 2. Selection of water for pharmaceutical purposes.

used for the preparation of official substances and other bulk pharmaceutical ingredients. Where compatible with the processes, the allowed contaminant levels in *Drinking Water* are generally considered safe for use for official substances and other drug substances. Where required by the processing of the materials to achieve their required final purity, higher qualities of water may be needed for these manufacturing steps, perhaps even as pure as *Water for Injection* or *Purified Water*. Such higher purity waters, however, might require only selected attributes to be of higher purity than *Drinking Water* (see Figure 2). *Drinking Water* is the prescribed source or feed water for the production of bulk monographed pharmaceutical waters. The use of *Drinking Water* specifications establishes a reasonable set of maximum allowable levels of chemical and microbiological contaminants with which a water purification system will be challenged. As seasonal variations in the quality attributes of the *Drinking Water* supply can occur, due consideration to its synthetic and cleaning uses must be given. The processing steps in the production of pharmaceutical waters must be designed to accommodate this variability.

Hot Purified Water—This water is used in the preparation instructions for *USP–NF* articles and is clearly intended to be *Purified Water* that has been heated to an unspecified

temperature in order to enhance solubilization of other ingredients. There is no upper temperature limit for the water (other than being less than 100°), but for each monograph there is an implied lower limit below which the desired solubilization effect would not occur.

Nonmonographed Analytical Waters

Both *General Notices and Requirements* and the introductory section to *Reagents, Indicators, and Solutions* clearly state that where the term “water,” without qualification or other specification, is indicated for use in analyses, the quality of water shall be *Purified Water*. However, numerous such qualifications do exist. Some of these qualifications involve methods of preparation, ranging from specifying the primary purification step to specifying additional purification. Other qualifications call for specific attributes to be met that might otherwise interfere with analytical processes. In most of these latter cases, the required attribute is not specifically tested. Rather, a further “purification process” is specified that ostensibly allows the water to adequately meet this required attribute.

However, preparation instructions for many reagents were carried forward from the innovator’s laboratories to the orig-

inally introduced monograph for a particular *USP–NF* article or general test chapter. The quality of the reagent water described in these tests may reflect the water quality designation of the innovator's laboratory. These specific water designations may have originated without the innovator's awareness of the requirement for *Purified Water* in *USP–NF* tests. Regardless of the original reason for the creation of these numerous special analytical waters, it is possible that the attributes of these special waters could now be met by the basic preparation steps and current specifications of *Purified Water*. In some cases, however, some of the cited post-processing steps are still necessary to reliably achieve the required attributes.

Users are not obligated to employ specific and perhaps archaically generated forms of analytical water where alternatives with equal or better quality, availability, or analytical performance may exist. The consistency and reliability for producing these alternative analytical waters should be verified as producing the desired attributes. In addition, any alternative analytical water must be evaluated on an application-by-application basis by the user to ensure its suitability. Following is a summary of the various types of nonmonographed analytical waters that are cited in the *USP–NF*.

Distilled Water—This water is produced by vaporizing liquid water and condensing it in a purer state. It is used primarily as a solvent for reagent preparation, but it is also specified in the execution of other aspects of tests, such as for rinsing an analyte, transferring a test material as a slurry, as a calibration standard or analytical blank, and for test apparatus cleaning. It is also cited as the starting water to be used for making *High-Purity Water*. Because none of the cited uses of this water imply a need for a particular purity attribute that can only be derived by distillation, water meeting the requirements for *Purified Water* derived by other means of purification could be equally suitable where *Distilled Water* is specified.

Freshly Distilled Water—Also called “recently distilled water”, it is produced in a similar fashion to *Distilled Water* and should be used shortly after its generation. This implies the need to avoid endotoxin contamination as well as any other adventitious forms of contamination from the air or containers that could arise with prolonged storage. It is used for preparing solutions for subcutaneous test animal injections as well as for a reagent solvent in tests for which there appears to be no particularly high water purity needed that could be ascribable to being “freshly distilled”. In the test animal use, the term “freshly distilled” and its testing use imply a chemical, endotoxin, and microbiological purity that could be equally satisfied by *Water for Injection* (though no reference is made to these chemical, endotoxin, or microbial attributes or specific protection from recontamination). For nonanimal uses, water meeting the requirements for *Purified Water* derived by other means of purification and/or storage periods could be equally suitable where “recently distilled water” or *Freshly Distilled Water* is specified.

Deionized Water—This water is produced by an ion-exchange process in which the contaminating ions are replaced with either H^+ or OH^- ions. Similarly to *Distilled Water*, *Deionized Water* is used primarily as a solvent for reagent preparation, but it is also specified in the execution of other aspects of tests, such as for transferring an analyte within a test procedure, as a calibration standard or analytical blank, and for test apparatus cleaning. Also, none of the cited uses of this water imply any needed purity attribute that can only be achieved by deionization. Therefore, water meeting the requirements for *Purified Water* that is derived by other means of purification could be equally suitable where *Deionized Water* is specified.

Freshly Deionized Water—This water is prepared in a similar fashion to *Deionized Water*, though as the name suggests, it is to be used shortly after its production. This implies the need to avoid any adventitious contamination that could occur upon storage. This water is indicated for use as

a reagent solvent as well as for cleaning. Due to the nature of the testing, *Purified Water* could be a reasonable alternative for these applications.

Deionized Distilled Water—This water is produced by deionizing (see *Deionized Water*) *Distilled Water*. This water is used as a reagent in a liquid chromatography test that requires a high purity. Because of the importance of this high purity, water that barely meets the requirements for *Purified Water* may not be acceptable. *High-Purity Water* (see below) could be a reasonable alternative for this water.

Filtered Water—This water is *Purified Water* that has been filtered to remove particles that could interfere with the analysis where this water is specified. It is sometimes used synonymously with *Particle-Free Water* and *Ultra-Filtered Water* and is cited in some monographs and general chapters as well as in *Reagents*. Depending on its location, it is variously defined as water that has been passed through filters rated as 1.2- μm , 0.22- μm , or 0.2- μm ; or unspecified pore size. Even though the water names and the filter pore sizes used to produce these waters are inconsistently defined, the use of 0.2- μm pore size filtered *Purified Water* should be universally acceptable for all applications where *Particle-Free Water*, *Filtered Water*, or *Ultra-Filtered Water* are specified.

High-Purity Water—The preparation of this water is defined in *Containers—Glass* (660). It is water that may be prepared by deionizing previously distilled water, and then filtering it through a 0.45- μm rated membrane. This water must have an in-line conductivity of not greater than 0.15 $\mu S/cm$ (not less than 6.67 Megohm-cm) at 25°. For the sake of purity comparison, the analogous Stage 1 and 2 conductivity requirements for *Purified Water* at the same temperature are 1.3 $\mu S/cm$ and 2.1 $\mu S/cm$, respectively. The preparation specified in *Containers—Glass* (660) uses materials that are highly efficient deionizers and that do not contribute copper ions or organics to the water, assuring a very high quality water. If the water of this purity contacts the atmosphere even briefly as it is being used or drawn from its purification system, its conductivity will immediately degrade, by as much as about 1.0 $\mu S/cm$, as atmospheric carbon dioxide dissolves in the water and equilibrates to bicarbonate ions. Therefore, if the analytical use requires that water purity remains as high as possible, its use should be protected from atmospheric exposure. This water is used as a reagent, as a solvent for reagent preparation, and for test apparatus cleaning where less pure waters would not perform acceptably. However, if a user's routinely available *Purified Water* is filtered and meets or exceeds the conductivity specifications of *High-Purity Water*, it could be used in lieu of *High-Purity Water*.

Ammonia-Free Water—Functionally, this water must have a negligible ammonia concentration to avoid interference in tests sensitive to ammonia. It has been equated with *High-Purity Water* that has a significantly tighter Stage 1 conductivity specification than *Purified Water* because of the latter's allowance for a minimal level of ammonium among other ions. However, if the user's *Purified Water* were filtered and met or exceeded the conductivity specifications of *High-Purity Water*, it would contain negligible ammonia or other ions and could be used in lieu of *High-Purity Water*.

Carbon Dioxide-Free Water—The introductory portion of the *Reagents, Indicators, and Solutions* section defines this water as *Purified Water* that has been vigorously boiled for at least 5 minutes, then cooled and protected from absorption of atmospheric carbon dioxide. Because the absorption of carbon dioxide tends to drive down the water pH, most of the uses of *Carbon Dioxide-Free Water* are either associated as a solvent in pH-related or pH-sensitive determinations or as a solvent in carbonate-sensitive reagents or determinations. Another use of this water is for certain optical rotation and color and clarity of solution tests. Though it is possible that this water is indicated for these tests simply because of its purity, it is also possible that the pH effects of carbon dioxide-containing water could interfere with the results of

these tests. A third plausible reason that this water is indicated is that outgassing air bubbles might interfere with these photometric-type tests. The boiled water preparation approach will also greatly reduce the concentrations of many other dissolved gases along with carbon dioxide. Therefore, in some of the applications for *Carbon Dioxide-Free Water*, it could be the inadvertent deaeration effect that actually renders this water suitable. In addition to boiling, deionization is perhaps an even more efficient process for removing dissolved carbon dioxide (by drawing the dissolved gas equilibrium toward the ionized state with subsequent removal by the ion-exchange resins). If the starting *Purified Water* is prepared by an efficient deionization process and protected after deionization from exposure to atmospheric air, water that is carbon dioxide-free can be effectively made without the application of heat. However, this deionization process does not deaerate the water, so if *Purified Water* prepared by deionization is considered as a substitute water in a test requiring *Carbon Dioxide-Free Water*, the user must verify that it is not actually water akin to *Deaerated Water* (discussed below) that is needed for the test. As indicated in *High-Purity Water*, even brief contact with the atmosphere can allow small amounts of carbon dioxide to dissolve, ionize, and significantly degrade the conductivity and lower the pH. If the analytical use requires the water to remain as pH-neutral and as carbon dioxide-free as possible, even the analysis should be protected from atmospheric exposure. However, in most applications, atmospheric exposure during testing does not significantly affect its suitability in the test.

Ammonia- and Carbon Dioxide-Free Water—As implied by the name, this water should be prepared by approaches compatible with those mentioned for both *Ammonia-Free Water* and *Carbon Dioxide-Free Water*. Because the carbon dioxide-free attribute requires post-production protection from the atmosphere, it is appropriate to first render the water ammonia-free using the *High-Purity Water* process followed by the boiling and carbon dioxide-protected cooling process. The *High-Purity Water* deionization process for creating *Ammonia-Free Water* will also remove the ions generated from dissolved carbon dioxide and ultimately, by forced equilibration to the ionized state, all the dissolved carbon dioxide. Therefore, depending on its use, an acceptable procedure for making *Ammonia- and Carbon Dioxide-Free Water* could be to transfer and collect *High-Purity Water* in a carbon dioxide intrusion-protected container.

Deaerated Water—This water is *Purified Water* that has been treated to reduce the content of dissolved air by “suitable means”. In the *Reagents* section, approaches for boiling, cooling (similar to *Carbon Dioxide-Free Water* but without the atmospheric carbon dioxide protection), and sonication are given as applicable for test uses other than dissolution and drug release testing. Though *Deaerated Water* is not mentioned by name in *Dissolution* <711>, suggested methods for deaerating dissolution media (which may be water) include warming to 41°, vacuum filtering through a 0.45-µm rated membrane, and vigorously stirring the filtrate while maintaining the vacuum. This chapter specifically indicates that other validated approaches may be used. In other monographs that also do not mention *Deaerated Water* by name, degassing of water and other reagents is accomplished by sparging with helium. *Deaerated Water* is used in both dissolution testing as well as liquid chromatography applications where outgassing could either interfere with the analysis itself or cause erroneous results due to inaccurate volumetric withdrawals. Applications where ambient temperature water is used for reagent preparation, but the tests are performed at elevated temperatures, are candidates for outgassing effects. If outgassing could interfere with test performance, including chromatographic flow, colorimetric or photometric measurements, or volumetric accuracy, then *Deaerated Water* should probably be used, whether called for in the analysis or not. The above deaeration approaches might not render the water “gas-free”. At

best, they reduce the dissolved gas concentrations so that outgassing caused by temperature changes is not likely.

Recently Boiled Water—This water may include recently or freshly boiled water (with or without mention of cooling in the title), but cooling prior to use is clearly intended. Occasionally it is necessary to use when hot. *Recently Boiled Water* is specified because it is used in a pH-related test or carbonate-sensitive reagent, in an oxygen-sensitive test or reagent, or in a test where outgassing could interfere with the analysis, such as specific gravity or an appearance test.

Oxygen-Free Water—The preparation of this water is not specifically described in the compendia. Neither is there an oxygen specification or analysis mentioned. However, all uses involve analyses of materials that could be sensitive to oxidation by atmospheric oxygen. Procedures for the removal of dissolved oxygen from solvents, though not necessarily water, are mentioned in *Polarography* <801> and *Spectrophotometry and Light-Scattering* <851>. These procedures involve simple sparging of the liquid with an inert gas such as nitrogen or helium, followed by inert gas blanketing to prevent oxygen reabsorption. The sparging times cited range from 5 to 15 minutes to an unspecified period. Some *Purified Water* and *Water for Injection* systems produce water that is maintained in a hot state and that is inert gas blanketed during its preparation and storage and distribution. Though oxygen is poorly soluble in hot water, such water may not be oxygen-free. Whatever procedure is used for removing oxygen should be verified as reliably producing water that is fit for use.

Water for BET—This water is also referred to as LAL reagent water. This is often *Water for Injection*, which may have been sterilized. It is free from a level of endotoxin that would yield any detectable reaction or interference with the *Limulus Amoebocyte Lysate* reagent used in the *Bacterial Endotoxins Test* <85>.

Organic-Free Water—This water is defined by *Residual Solvents* <467> as producing no significantly interfering gas chromatography peaks. Referenced monographs specify using this water as the solvent for the preparation of standard and test solutions for the *Residual solvents* test.

Lead-Free Water—This water is used as a transferring diluent for an analyte in a *Lead* <251> test. Though no specific instructions are given for its preparation, it must not contain any detectable lead. *Purified Water* should be a suitable substitute for this water.

Chloride-Free Water—This water is specified as the solvent for use in an assay that contains a reactant that precipitates in the presence of chloride. Though no specific preparation instructions are given for this water, its rather obvious attribute is having a very low chloride level in order to be unreactive with this chloride sensitive reactant. *Purified Water* could be used for this water but should be tested to ensure that it is unreactive.

Hot Water—The uses of this water include solvents for achieving or enhancing reagent solubilization, restoring the original volume of boiled or hot solutions, rinsing insoluble analytes free of hot water soluble impurities, solvents for reagent recrystallization, apparatus cleaning, and as a solubility attribute for various *USP-NF* articles. In only one monograph is the temperature of “hot” water specified; so in all the other cases, the water temperature is less important, but should be high enough to achieve the desirable effect. In all cases, the chemical quality of the water is implied to be that of *Purified Water*.

VALIDATION AND QUALIFICATION OF WATER PURIFICATION, STORAGE, AND DISTRIBUTION SYSTEMS

Establishing the dependability of pharmaceutical water purification, storage, and distribution systems requires an appropriate period of monitoring and observation. Ordinar-

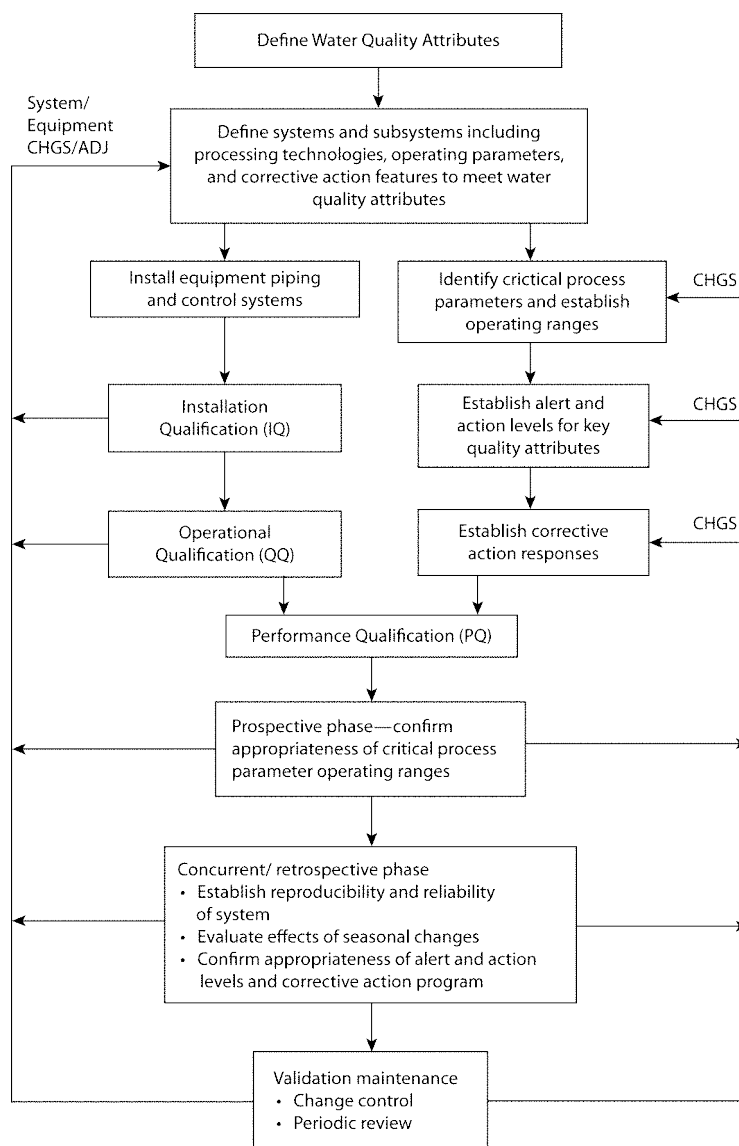

Figure 3. Water system validation life cycle.

ily, few problems are encountered in maintaining the chemical purity of *Purified Water* and *Water for Injection*. Nevertheless, the advent of using conductivity and TOC to define chemical purity has allowed the user to more quantitatively assess the water's chemical purity and its variability as a function of routine pretreatment system maintenance and regeneration. Even the presence of such unit operations as heat exchangers and use point hoses can compromise the chemical quality of water within and delivered from an otherwise well-controlled water system. Therefore, an assessment of the consistency of the water's chemical purity over time must be part of the validation program. However, even with the most well controlled chemical quality, it is often more difficult to consistently meet established microbiological quality criteria owing to phenomena occurring during and after chemical purification. A typical program involves intensive daily sampling and testing of major process points for at least one month after operational criteria have been established for each unit operation, point of use, and sampling point.

An overlooked aspect of water system validation is the delivery of the water to its actual location of use. If this transfer process from the distribution system outlets to the water use locations (usually with hoses) is defined as outside

the water system, then this transfer process still needs to be validated to not adversely affect the quality of the water to the extent it becomes unfit for use. Because routine microbial monitoring is performed for the same transfer process and components (e.g., hoses and heat exchangers) as that of routine water use (see *Sampling Considerations*), there is some logic to including this water transfer process within the distribution system validation.

Validation is the process whereby substantiation to a high level of assurance that a specific process will consistently produce a product conforming to an established set of quality attributes is acquired and documented. Prior to and during the very early stages of validation, the critical process parameters and their operating ranges are established. A validation program qualifies and documents the design, installation, operation, and performance of equipment. It begins when the system is defined and moves through several stages: installation qualification (IQ), operational qualification (OQ), and performance qualification (PQ). A graphical representation of a typical water system validation life cycle is shown in *Figure 3*.

A validation plan for a water system typically includes the following steps: (1) establishing standards for quality attributes of the finished water and the source water; (2) defining

suitable unit operations and their operating parameters for achieving the desired finished water quality attributes from the available source water; (3) selecting piping, equipment, controls, and monitoring technologies; (4) developing an IQ stage consisting of instrument calibrations, inspections to verify that the drawings accurately depict the final configuration of the water system and, where necessary, special tests to verify that the installation meets the design requirements; (5) developing an OQ stage consisting of tests and inspections to verify that the equipment, system alerts, and controls are operating reliably and that appropriate alert and action levels are established (This phase of qualification may overlap with aspects of the next step.); and (6) developing a prospective PQ stage to confirm the appropriateness of critical process parameter operating ranges (During this phase of validation, alert and action levels for key quality attributes and operating parameters are verified.); (7) assuring the adequacy of ongoing control procedures, e.g., sanitization frequency; (8) supplementing a validation maintenance program (also called continuous validation life cycle) that includes a mechanism to control changes to the water system and establishes and carries out scheduled preventive maintenance including recalibration of instruments (In addition, validation maintenance includes a monitoring program for critical process parameters and a corrective action program.); (9) instituting a schedule for periodic review of the system performance and requalification; and (10) completing protocols and documenting Steps 1 through 9.

PURIFIED WATER AND WATER FOR INJECTION SYSTEMS

The design, installation, and operation of systems to produce *Purified Water* and *Water for Injection* include similar components, control techniques, and procedures. The quality attributes of both waters differ only in the presence of a bacterial endotoxin requirement for *Water for Injection* and in their methods of preparation, at least at the last stage of preparation. The similarities in the quality attributes provide considerable common ground in the design of water systems to meet either requirement. The critical difference is the degree of control of the system and the final purification steps needed to ensure bacterial and bacterial endotoxin removal.

Production of pharmaceutical water employs sequential unit operations (processing steps) that address specific water quality attributes and protect the operation of subsequent treatment steps. A typical evaluation process to select an appropriate water quality for a particular pharmaceutical purpose is shown in the decision tree in *Figure 2*. This diagram may be used to assist in defining requirements for specific water uses and in the selection of unit operations. The final unit operation used to produce *Water for Injection* is limited to distillation or other processes equivalent or superior to distillation in the removal of chemical impurities as well as microorganisms and their components. Distillation has a long history of reliable performance and can be validated as a unit operation for the production of *Water for Injection*, but other technologies or combinations of technologies can be validated as being equivalently effective. Other technologies, such as ultrafiltration following another chemical purification process, may be suitable in the production of *Water for Injection* if they can be shown through validation to be as effective and reliable as distillation. The advent of new materials for older technologies, such as reverse osmosis and ultrafiltration, that allow intermittent or continuous operation at elevated, microbial temperatures, show promise for a valid use in producing *Water for Injection*.

The validation plan should be designed to establish the suitability of the system and to provide a thorough understanding of the purification mechanism, range of operating conditions, required pretreatment, and the most likely modes of failure. It is also necessary to demonstrate the effectiveness of the monitoring scheme and to establish the

documentation and qualification requirements for the system's validation maintenance. Trials conducted in a pilot installation can be valuable in defining the operating parameters and the expected water quality and in identifying failure modes. However, qualification of the specific unit operation can only be performed as part of the validation of the installed operational system. The selection of specific unit operations and design characteristics for a water system should take into account the quality of the feed water, the technology chosen for subsequent processing steps, the extent and complexity of the water distribution system, and the appropriate compendial requirements. For example, in the design of a system for *Water for Injection*, the final process (distillation or whatever other validated process is used according to the monograph) must have effective bacterial endotoxin reduction capability and must be validated.

UNIT OPERATIONS CONCERNS

The following is a brief description of selected unit operations and the operation and validation concerns associated with them. Not all unit operations are discussed, nor are all potential problems addressed. The purpose is to highlight issues that focus on the design, installation, operation, maintenance, and monitoring parameters that facilitate water system validation.

Prefiltration

The purpose of prefiltration—also referred to as initial, coarse, or depth filtration—is to remove solid contaminants down to a size of 7 to 10 μm from the incoming source water supply and protect downstream system components from particulates that can inhibit equipment performance and shorten their effective life. This coarse filtration technology utilizes primarily sieving effects for particle capture and a depth of filtration medium that has a high “dirt load” capacity. Such filtration units are available in a wide range of designs and for various applications. Removal efficiencies and capacities differ significantly, from granular bed filters such as multimedia or sand for larger water systems, to depth cartridges for smaller water systems. Unit and system configurations vary widely in type of filtering media and location in the process. Granular or cartridge prefilters are often situated at or near the head of the water pretreatment system prior to unit operations designed to remove the source water disinfectants. This location, however, does not preclude the need for periodic microbial control because biofilm can still proliferate, although at a slower rate in the presence of source water disinfectants. Design and operational issues that may impact performance of depth filters include channeling of the filtering media, blockage from silt, microbial growth, and filtering-media loss during improper backwashing. Control measures involve pressure and flow monitoring during use and backwashing, sanitizing, and replacing filtering media. An important design concern is sizing of the filter to prevent channeling or media loss resulting from inappropriate water flow rates as well as proper sizing to minimize excessively frequent or infrequent backwashing or cartridge filter replacement.

Activated Carbon

Granular activated carbon beds adsorb low molecular weight organic material and oxidizing additives, such as chlorine and chloramine compounds, removing them from the water. They are used to achieve certain quality attributes and to protect against reaction with downstream stainless steel surfaces, resins, and membranes. The chief operating concerns regarding activated carbon beds include the propensity to support bacteria growth, the potential for hydraulic channeling, the organic adsorption capacity, appropriate water flow rates and contact time, the inability to be

regenerated in situ, and the shedding of bacteria, endotoxins, organic chemicals, and fine carbon particles. Control measures may involve monitoring water flow rates and differential pressures, sanitizing with hot water or steam, backwashing, testing for adsorption capacity, and frequent replacement of the carbon bed. If the activated carbon bed is intended for organic reduction, it may also be appropriate to monitor influent and effluent TOC. It is important to note that the use of steam for carbon bed sanitization is often incompletely effective due to steam channeling rather than even permeation through the bed. This phenomenon can usually be avoided by using hot water sanitization. It is also important to note that microbial biofilm development on the surface of the granular carbon particles (as well as on other particles such as found in deionizer beds and even multimedia beds) can cause adjacent bed granules to "stick" together. When large masses of granules are agglomerated in this fashion, normal backwashing and bed fluidization flow parameters may not be sufficient to disperse them, leading to ineffective removal of trapped debris, loose biofilm, and penetration of microbial controlling conditions (as well as regenerant chemicals as in the case of agglomerated deionizer resins). Alternative technologies to activated carbon beds can be used in order to avoid their microbial problems, such as disinfectant-neutralizing chemical additives and regenerable organic scavenging devices. However, these alternatives do not function by the same mechanisms as activated carbon, may not be as effective at removing disinfectants and some organics, and have a different set of operating concerns and control measures that may be nearly as troublesome as activated carbon beds.

Additives

Chemical additives are used in water systems (a) to control microorganisms by use of sanitants such as chlorine compounds and ozone, (b) to enhance the removal of suspended solids by use of flocculating agents, (c) to remove chlorine compounds, (d) to avoid scaling on reverse osmosis membranes, and (e) to adjust pH for more effective removal of carbonate and ammonia compounds by reverse osmosis. These additives do not constitute "added substances" as long as they are either removed by subsequent processing steps or are otherwise absent from the finished water. Control of additives to ensure a continuously effective concentration and subsequent monitoring to ensure their removal should be designed into the system and included in the monitoring program.

Organic Scavengers

Organic scavenging devices use macroreticular weakly basic anion-exchange resins capable of removing organic material and endotoxins from the water. They can be regenerated with appropriate biocidal caustic brine solutions. Operating concerns are associated with organic scavenging capacity, particulate, chemical and microbiological fouling of the reactive resin surface, flow rate, regeneration frequency, and shedding of resin fragments. Control measures include TOC testing of influent and effluent, backwashing, monitoring hydraulic performance, and using downstream filters to remove resin fines.

Softeners

Water softeners may be located either upstream or downstream of disinfectant removal units. They utilize sodium-based cation-exchange resins to remove water-hardness ions, such as calcium and magnesium, that could foul or interfere with the performance of downstream processing equipment such as reverse osmosis membranes, deionization devices, and distillation units. Water softeners can also be used to remove other lower affinity cations, such as the am-

monium ion, that may be released from chloramine disinfectants commonly used in drinking water and which might otherwise carryover through other downstream unit operations. If ammonium removal is one of its purposes, the softener must be located downstream of the disinfectant removal operation, which itself may liberate ammonium from neutralized chloramine disinfectants. Water softener resin beds are regenerated with concentrated sodium chloride solution (brine). Concerns include microorganism proliferation, channeling caused by biofilm agglomeration of resin particles, appropriate water flow rates and contact time, ion-exchange capacity, organic and particulate resin fouling, organic leaching from new resins, fracture of the resin beads, resin degradation by excessively chlorinated water, and contamination from the brine solution used for regeneration. Control measures involve recirculation of water during periods of low water use, periodic sanitization of the resin and brine system, use of microbial control devices (e.g., UV light and chlorine), locating the unit upstream of the disinfectant removal step (if used only for softening), appropriate regeneration frequency, effluent chemical monitoring (e.g., hardness ions and possibly ammonium), and downstream filtration to remove resin fines. If a softener is used for ammonium removal from chloramine-containing source water, then capacity, contact time, resin surface fouling, pH, and regeneration frequency are very important.

Deionization

Deionization (DI), and continuous electrodeionization (CEDI) are effective methods of improving the chemical quality attributes of water by removing cations and anions. DI systems have charged resins that require periodic regeneration with an acid and base. Typically, cationic resins are regenerated with either hydrochloric or sulfuric acid, which replace the captured positive ions with hydrogen ions. Anionic resins are regenerated with sodium or potassium hydroxide, which replace captured negative ions with hydroxide ions. Because free endotoxin is negatively charged, there is some removal of endotoxin achieved by the anionic resin. Both regenerant chemicals are biocidal and offer a measure of microbial control. The system can be designed so that the cation and anion resins are in separate or "twin" beds or they can be mixed together to form a mixed bed. Twin beds are easily regenerated but deionize water less efficiently than mixed beds, which have a considerably more complex regeneration process. Rechargeable resin canisters can also be used for this purpose.

The CEDI system uses a combination of mixed resin, selectively permeable membranes, and an electric charge, providing continuous flow (product and waste concentrate) and continuous regeneration. Water enters both the resin section and the waste (concentrate) section. As it passes through the resin, it is deionized to become product water. The resin acts as a conductor enabling the electrical potential to drive the captured cations and anions through the resin and appropriate membranes for concentration and removal in the waste water stream. The electrical potential also separates the water in the resin (product) section into hydrogen and hydroxide ions. This permits continuous regeneration of the resin without the need for regenerant additives. However, unlike conventional deionization, CEDI units must start with water that is already partially purified because they generally cannot produce *Purified Water* quality when starting with the heavier ion load of unpurified source water.

Concerns for all forms of deionization units include microbial and endotoxin control, chemical additive impact on resins and membranes, and loss, degradation, and fouling of resin. Issues of concern specific to DI units include regeneration frequency and completeness, channeling caused by biofilm agglomeration of resin particles, organic leaching from new resins, complete resin separation for mixed bed regeneration, and mixing air contamination (mixed beds). Control

measures vary but typically include recirculation loops, effluent microbial control by UV light, conductivity monitoring, resin testing, microporous filtration of mixing air, microbial monitoring, frequent regeneration to minimize and control microorganism growth, sizing the equipment for suitable water flow and contact time, and use of elevated temperatures. Internal distributor and regeneration piping for mixed bed units should be configured to ensure that regeneration chemicals contact all internal bed and piping surfaces and resins. Rechargeable canisters can be the source of contamination and should be carefully monitored. Full knowledge of previous resin use, minimum storage time between regeneration and use, and appropriate sanitizing procedures are critical factors ensuring proper performance.

Reverse Osmosis

Reverse osmosis (RO) units employ semipermeable membranes. The "pores" of RO membranes are actually intersegmental spaces among the polymer molecules. They are big enough for permeation of water molecules, but too small to permit passage of hydrated chemical ions. However, many factors including pH, temperature, and differential pressure across the membrane affect the selectivity of this permeation. With the proper controls, RO membranes can achieve chemical, microbial, and endotoxin quality improvement. The process streams consist of supply water, product water (permeate), and wastewater (reject). Depending on source water, pretreatment and system configuration variations and chemical additives may be necessary to achieve desired performance and reliability.

A major factor affecting RO performance is the permeate recovery rate, that is, the amount of the water passing through the membrane compared to the amount rejected. This is influenced by the several factors, but most significantly by the pump pressure. Recoveries of 75% are typical, and can accomplish a 1 to 2 log purification of most impurities. For most feed waters, this is usually not enough to meet *Purified Water* conductivity specifications. A second pass of this permeate water through another RO stage usually achieves the necessary permeate purity if other factors such as pH and temperature have been appropriately adjusted and the ammonia from chloraminated source water has been previously removed. Increasing recoveries with higher pressures in order to reduce the volume of reject water will lead to reduced permeate purity. If increased pressures are needed over time to achieve the same permeate flow, this is an indication of partial membrane blockage that needs to be corrected before it becomes irreversibly fouled, and expensive membrane replacement is the only option.

Other concerns associated with the design and operation of RO units include membrane materials that are extremely sensitive to sanitizing agents and to particulate, chemical, and microbial membrane fouling; membrane and seal integrity; the passage of dissolved gases, such as carbon dioxide and ammonia; and the volume of wastewater, particularly where water discharge is tightly regulated by local authorities. Failure of membrane or seal integrity will result in product water contamination. Methods of control involve suitable pretreatment of the influent water stream, appropriate membrane material selection, integrity challenges, membrane design and heat tolerance, periodic sanitization, and monitoring of differential pressures, conductivity, microbial levels, and TOC.

The development of RO units that can tolerate sanitizing water temperatures as well as operate efficiently and continuously at elevated temperatures has added greatly to their microbial control and to the avoidance of biofouling. RO units can be used alone or in combination with DI and CEDI units as well as ultrafiltration for operational and quality enhancements.

Ultrafiltration

Ultrafiltration is a technology most often employed in pharmaceutical water systems for removing endotoxins from a water stream. It can also use semipermeable membranes, but unlike RO, these typically use polysulfone membranes whose intersegmental "pores" have been purposefully exaggerated during their manufacture by preventing the polymer molecules from reaching their smaller equilibrium proximities to each other. Depending on the level of equilibrium control during their fabrication, membranes with differing molecular weight "cutoffs" can be created such that molecules with molecular weights above these cutoffs ratings are rejected and cannot penetrate the filtration matrix.

Ceramic ultrafilters are another molecular sieving technology. Ceramic ultrafilters are self supporting and extremely durable, backwashable, chemically cleanable, and steam sterilizable. However, they may require higher operating pressures than membrane type ultrafilters.

All ultrafiltration devices work primarily by a molecular sieving principle. Ultrafilters with molecular weight cutoff ratings in the range of 10,000 to 20,000 Da are typically used in water systems for removing endotoxins. This technology may be appropriate as an intermediate or final purification step. Similar to RO, successful performance is dependent upon pretreatment of the water by upstream unit operations.

Issues of concern for ultrafilters include compatibility of membrane material with heat and sanitizing agents, membrane integrity, fouling by particles and microorganisms, and seal integrity. Control measures involve filtration medium selection, sanitization, flow design (dead end vs. tangential), integrity challenges, regular cartridge changes, elevated feed water temperature, and monitoring TOC and differential pressure. Additional flexibility in operation is possible based on the way ultrafiltration units are arranged such as in a parallel or series configurations. Care should be taken to avoid stagnant water conditions that could promote microorganism growth in back-up or standby units.

Charge-Modified Filtration

Charge-modified filters are usually microbially retentive filters that are treated during their manufacture to have a positive charge on their surfaces. Microbial retentive filtration will be described in a subsequent section, but the significant feature of these membranes is their electrostatic surface charge. Such charged filters can reduce endotoxin levels in the fluids passing through them by their adsorption (owing to endotoxin's negative charge) onto the membrane surfaces. Though ultrafilters are more often employed as a unit operation for endotoxin removal in water systems, charge-modified filters may also have a place in endotoxin removal particularly where available upstream pressures are not sufficient for ultrafiltration and for a single, relatively short term use. Charge-modified filters may be difficult to validate for long-term or large-volume endotoxin retention. Even though their purified standard endotoxin retention can be well characterized, their retention capacity for "natural" endotoxins is difficult to gauge. Nevertheless, utility could be demonstrated and validated as short-term, single-use filters at points of use in water systems that are not designed for endotoxin control or where only an endotoxin "polishing" (removal of only slight or occasional endotoxin levels) is needed. Control and validation concerns include volume and duration of use, flow rate, water conductivity and purity, and constancy and concentration of endotoxin levels being removed. All of these factors may have to be evaluated and challenged prior to using this approach, making this a difficult-to-validate application. Even so, there may still be a possible need for additional backup endotoxin testing both upstream and downstream of the filter.

Microbial-Retentive Filtration

Microbial-retentive membrane filters have experienced an evolution of understanding in the past decade that has caused previously held theoretical retention mechanisms to be reconsidered. These filters have a larger effective "pore size" than ultrafilters and are intended to prevent the passage of microorganisms and similarly sized particles without unduly restricting flow. This type of filtration is widely employed within water systems for filtering the bacteria out of both water and compressed gases as well as for vent filters on tanks and stills and other unit operations. However, the properties of the water system microorganisms seem to challenge a filter's microbial retention from water with phenomena absent from other aseptic filtration applications, such as filter sterilizing of pharmaceutical formulations prior to packaging. In the latter application, sterilizing grade filters are generally considered to have an assigned rating of 0.2 or 0.22 μm . This rather arbitrary rating is associated with filters that have the ability to retain a high level challenge of a specially prepared inoculum of *Brevundimonas* (formerly *Pseudomonas*) *diminuta*. This is a small microorganism originally isolated decades ago from a product that had been "filter sterilized" using a 0.45- μm rated filter. Further study revealed that a percentage of cells of this microorganism could reproducibly penetrate the 0.45- μm sterilizing filters. Through historic correlation of *B. diminuta* retaining tighter filters, thought to be twice as good as 0.45- μm filter, assigned ratings of 0.2 or 0.22 μm with their successful use in product solution filter sterilization, both this filter rating and the associated high level *B. diminuta* challenge have become the current benchmarks for sterilizing filtration. New evidence now suggests that for microbial-retentive filters used for pharmaceutical water, *B. diminuta* may not be the best model microorganism.

An archaic understanding of microbial retentive filtration would lead one to equate a filter's rating with the false impression of a simple sieve or screen that absolutely retains particles sized at or above the filter's rating. A current understanding of the mechanisms involved in microbial retention and the variables that can affect those mechanisms has yielded a far more complex interaction of phenomena than previously understood. A combination of simple sieve retention and surface adsorption are now known to contribute to microbial retention.

The following all interact to create some unusual and surprising retention phenomena for water system microorganisms: the variability in the range and average pore sizes created by the various membrane fabrication processes, the variability of the surface chemistry and three-dimensional structure related to the different polymers used in these filter matrices, and the size and surface properties of the microorganism intended to be retained by the filters. *B. diminuta* may not be the best challenge microorganisms for demonstrating bacterial retention for 0.2- to 0.22- μm rated filters for use in water systems because it appears to be more easily retained by these filters than some water system flora. The well-documented appearance of water system microorganisms on the downstream sides of some 0.2- to 0.22- μm rated filters after a relatively short period of use seems to support that some penetration phenomena are at work. Unknown for certain is if this downstream appearance is caused by a "blow-through" or some other pass-through phenomenon as a result of tiny cells or less cell "stickiness", or by a "growth through" phenomenon as a result of cells hypothetically replicating their way through the pores to the downstream side. Whatever is the penetration mechanism, 0.2- to 0.22- μm rated membranes may not be the best choice for some water system uses.

Microbial retention success in water systems has been reported with the use of some manufacturers' filters arbitrarily rated as 0.1 μm . There is general agreement that for a given manufacturer, their 0.1- μm rated filters are tighter than their

0.2- to 0.22- μm rated filters. However, comparably rated filters from different manufacturers in water filtration applications may not perform equivalently owing to the different filter fabrication processes and the nonstandardized microbial retention challenge processes currently used for defining the 0.1- μm filter rating. It should be noted that use of 0.1- μm rated membranes generally results in a sacrifice in flow rate compared to 0.2- to 0.22- μm membranes, so whatever membranes are chosen for a water system application, the user must verify that the membranes are suitable for their intended application, use period, and use process, including flow rate.

For microbial retentive gas filtrations, the same sieving and adsorptive retention phenomena are at work as in liquid filtration, but the adsorptive phenomenon is enhanced by additional electrostatic interactions between particles and filter matrix. These electrostatic interactions are so strong that particle retention for a given filter rating is significantly more efficient in gas filtration than in water or product solution filtrations. These additional adsorptive interactions render filters rated at 0.2 to 0.22 μm unquestionably suitable for microbial retentive gas filtrations. When microbially retentive filters are used in these applications, the membrane surface is typically hydrophobic (non-wettable by water). A significant area of concern for gas filtration is blockage of tank vents by condensed water vapor, which can cause mechanical damage to the tank. Control measures include electrical or steam tracing and a self-draining orientation of vent filter housings to prevent accumulation of vapor condensate. However, a continuously high filter temperature will take an oxidative toll on polypropylene components of the filter, so sterilization of the unit prior to initial use, and periodically thereafter, as well as regular visual inspections, integrity tests, and changes are recommended control methods.

In water applications, microbial retentive filters may be used downstream of unit operations that tend to release microorganisms or upstream of unit operations that are sensitive to microorganisms. Microbial retentive filters may also be used to filter water feeding the distribution system. It should be noted that regulatory authorities allow the use of microbial retentive filters within distribution systems or even at use points if they have been properly validated and are appropriately maintained. A point-of-use filter should only be intended to "polish" the microbial quality of an otherwise well-maintained system and not to serve as the primary microbial control device. The efficacy of system microbial control measures can only be assessed by sampling the water upstream of the filters. As an added measure of protection, in-line UV lamps, appropriately sized for the flow rate (see *Sanitization*), may be used just upstream of microbial retentive filters to inactivate microorganisms prior to their capture by the filter. This tandem approach tends to greatly delay potential microbial penetration phenomena and can substantially extend filter service life.

Ultraviolet Light

The use of low-pressure UV lights that emit a 254-nm wavelength for microbial control is discussed under *Sanitization*, but the application of UV light in chemical purification is also emerging. This 254-nm wavelength is also useful in the destruction of ozone. With intense emissions at wavelengths around 185 nm (as well as at 254 nm), medium pressure UV lights have demonstrated utility in the destruction of the chlorine-containing disinfectants used in source water as well as for interim stages of water pretreatment. High intensities of this wavelength alone or in combination with other oxidizing sanitants, such as hydrogen peroxide, have been used to lower TOC levels in recirculating distribution systems. The organics are typically converted to carbon dioxide, which equilibrates to bicarbonate, and incompletely oxidized carboxylic acids, both of which can easily be removed by polishing ion-exchange resins. Areas of concern

include adequate UV intensity and residence time, gradual loss of UV emissivity with bulb age, gradual formation of UV-absorbing film at the water contact surface, incomplete photodegradation during unforeseen source water hyper-chlorination, release of ammonia from chloramine photodegradation, unapparent UV bulb failure, and conductivity degradation in distribution systems using 185-nm UV lights. Control measures include regular inspection or emissivity alarms to detect bulb failures or film occlusions, regular UV bulb sleeve cleaning and wiping, downstream chlorine detectors, downstream polishing deionizers, and regular (approximately yearly) bulb replacement.

Distillation

Distillation units provide chemical and microbial purification via thermal vaporization, mist elimination, and water vapor condensation. A variety of designs is available including single effect, multiple effect, and vapor compression. The latter two configurations are normally used in larger systems because of their generating capacity and efficiency. Distilled water systems require different feed water controls than required by membrane systems. For distillation, due consideration must be given to prior removal of hardness and silica impurities that may foul or corrode the heat transfer surfaces as well as prior removal of those impurities that could volatilize and condense along with the water vapor. In spite of general perceptions, even the best distillation process cannot afford absolute removal of contaminating ions and endotoxin. Most stills are recognized as being able to accomplish at least a 3 to 4 log reduction in these impurity concentrations. Areas of concern include carry-over of volatile organic impurities such as trihalomethanes (see *Source and Feed Water Considerations*) and gaseous impurities such as ammonia and carbon dioxide, faulty mist elimination, evaporator flooding, inadequate blowdown, stagnant water in condensers and evaporators, pump and compressor seal design, pinhole evaporator and condenser leaks, and conductivity (quality) variations during start-up and operation.

Methods of control may involve preliminary decarbonation steps to remove both dissolved carbon dioxide and other volatile or noncondensable impurities; reliable mist elimination to minimize feedwater droplet entrainment; visual or automated high water level indication to detect boiler flooding and boil over; use of sanitary pumps and compressors to minimize microbial and lubricant contamination of feedwater and condensate; proper drainage during inactive periods to minimize microbial growth and accumulation of associated endotoxin in boiler water; blow down control to limit the impurity concentration effect in the boiler to manageable levels; on-line conductivity sensing with automated diversion to waste to prevent unacceptable water upon still startup or still malfunction from getting into the finished water distribute system; and periodic integrity testing for pinhole leaks to routinely assure condensate is not compromised by nonvolatilized source water contaminants.

Storage Tanks

Storage tanks are included in water distribution systems to optimize processing equipment capacity. Storage also allows for routine maintenance within the pretreatment train while maintaining continuous supply to meet manufacturing needs. Design and operation considerations are needed to prevent or minimize the development of biofilm, to minimize corrosion, to aid in the use of chemical sanitization of the tanks, and to safeguard mechanical integrity. These considerations may include using closed tanks with smooth interiors, the ability to spray the tank headspace using sprayballs on recirculating loop returns, and the use of heated, jacketed/insulated tanks. This minimizes corrosion and biofilm development and aids in thermal and chemical sanitization. Storage tanks require venting to compensate for the dynamics of changing water levels. This can be ac-

complished with a properly oriented and heat-traced filter housing fitted with a hydrophobic microbial retentive membrane filter affixed to an atmospheric vent. Alternatively, an automatic membrane-filtered compressed gas blanketing system may be used. In both cases, rupture disks equipped with a rupture alarm device should be used as a further safeguard for the mechanical integrity of the tank. Areas of concern include microbial growth or corrosion due to irregular or incomplete sanitization and microbial contamination from unalarmed rupture disk failures caused by condensate-occluded vent filters.

Distribution Systems

Distribution system configuration should allow for the continuous flow of water in the piping by means of recirculation. Use of nonrecirculating, dead-end, or one-way systems or system segments should be avoided whenever possible. If not possible, these systems should be periodically flushed and more closely monitored. Experience has shown that continuously recirculated systems are easier to maintain. Pumps should be designed to deliver fully turbulent flow conditions to facilitate thorough heat distribution (for hot water sanitized systems) as well as thorough chemical sanitant distribution. Turbulent flow also appear to either retard the development of biofilms or reduce the tendency of those biofilms to shed bacteria into the water. If redundant pumps are used, they should be configured and used to avoid microbial contamination of the system.

Components and distribution lines should be sloped and fitted with drain points so that the system can be completely drained. In stainless steel distribution systems where the water is circulated at a high temperature, dead legs and low-flow conditions should be avoided, and valved tie-in points should have length-to-diameter ratios of six or less. If constructed of heat tolerant plastic, this ratio should be even less to avoid cool points where biofilm development could occur. In ambient temperature distribution systems, particular care should be exercised to avoid or minimize dead leg ratios of any size and provide for complete drainage. If the system is intended to be steam sanitized, careful sloping and low-point drainage is crucial to condensate removal and sanitization success. If drainage of components or distribution lines is intended as a microbial control strategy, they should also be configured to be completely dried using dry compressed air (or nitrogen if appropriate employee safety measures are used). Drained but still moist surfaces will still support microbial proliferation. Water exiting from the distribution system should not be returned to the system without first passing through all or a portion of the purification train.

The distribution design should include the placement of sampling valves in the storage tank and at other locations, such as in the return line of the recirculating water system. Where feasible, the primary sampling sites for water should be the valves that deliver water to the points of use. Direct connections to processes or auxiliary equipment should be designed to prevent reverse flow into the controlled water system. Hoses and heat exchangers that are attached to points of use in order to deliver water for a particular use must not chemically or microbiologically degrade the water quality. The distribution system should permit sanitization for microorganism control. The system may be continuously operated at sanitizing conditions or sanitized periodically.

INSTALLATION, MATERIALS OF CONSTRUCTION, AND COMPONENT SELECTION

Installation techniques are important because they can affect the mechanical, corrosive, and sanitary integrity of the system. Valve installation attitude should promote gravity drainage. Pipe supports should provide appropriate slopes

for drainage and should be designed to support the piping adequately under worst-case thermal and flow conditions. The methods of connecting system components including units of operation, tanks, and distribution piping require careful attention to preclude potential problems. Stainless steel welds should provide reliable joints that are internally smooth and corrosion-free. Low-carbon stainless steel, compatible wire filler, where necessary, inert gas, automatic welding machines, and regular inspection and documentation help to ensure acceptable weld quality. Follow-up cleaning and passivation are important for removing contamination and corrosion products and to re-establish the passive corrosion resistant surface. Plastic materials can be fused (welded) in some cases and also require smooth, uniform internal surfaces. Adhesive glues and solvents should be avoided due to the potential for voids and extractables. Mechanical methods of joining, such as flange fittings, require care to avoid the creation of offsets, gaps, penetrations, and voids. Control measures include good alignment, properly sized gaskets, appropriate spacing, uniform sealing force, and the avoidance of threaded fittings.

Materials of construction should be selected to be compatible with control measures such as sanitizing, cleaning, and passivating. Temperature rating is a critical factor in choosing appropriate materials because surfaces may be required to handle elevated operating and sanitization temperatures. Should chemicals or additives be used to clean, control, or sanitize the system, materials resistant to these chemicals or additives must be utilized. Materials should be capable of handling turbulent flow and elevated velocities without wear of the corrosion-resistant film such as the passive chromium oxide surface of stainless steel. The finish on metallic materials such as stainless steel, whether it is a refined mill finish, polished to a specific grit, or an electropolished treatment, should complement system design and provide satisfactory corrosion and microbial activity resistance as well as chemical sanitizability. Auxiliary equipment and fittings that require seals, gaskets, diaphragms, filter media, and membranes should exclude materials that permit the possibility of extractables, shedding, and microbial activity. Insulating materials exposed to stainless steel surfaces should be free of chlorides to avoid the phenomenon of stress corrosion cracking that can lead to system contamination and the destruction of tanks and critical system components.

Specifications are important to ensure proper selection of materials and to serve as a reference for system qualification and maintenance. Information such as mill reports for stainless steel and reports of composition, ratings, and material handling capabilities for nonmetallic substances should be reviewed for suitability and retained for reference. Component (auxiliary equipment) selection should be made with assurance that it does not create a source of contamination intrusion. Heat exchangers should be constructed to prevent leakage of heat transfer medium to the pharmaceutical water and, for heat exchanger designs where prevention may fail, there should be a means to detect leakage. Pumps should be of sanitary design with seals that prevent contamination of the water. Valves should have smooth internal surfaces with the seat and closing device exposed to the flushing action of water, such as occurs in diaphragm valves. Valves with pocket areas or closing devices (e.g., ball, plug, gate, globe) that move into and out of the flow area should be avoided.

SANITIZATION

Microbial control in water systems is achieved primarily through sanitization practices. Systems can be sanitized using either thermal or chemical means. Thermal approaches to system sanitization include periodic or continuously circulating hot water and the use of steam. Temperatures of at least 80° are most commonly used for this purpose, but

continuously recirculating water of at least 65° has also been used effectively in insulated stainless steel distribution systems when attention is paid to uniformity and distribution of such self-sanitizing temperatures. These techniques are limited to systems that are compatible with the higher temperatures needed to achieve sanitization. Although thermal methods control biofilm development by either continuously inhibiting their growth or, in intermittent applications, by killing the microorganisms within biofilms, they are not effective in removing established biofilms. Killed but intact biofilms can become a nutrient source for rapid biofilm regrowth after the sanitizing conditions are removed or halted. In such cases, a combination of routine thermal and periodic supplementation with chemical sanitization might be more effective. The more frequent the thermal sanitization, the more likely biofilm development and regrowth can be eliminated. Chemical methods, where compatible, can be used on a wider variety of construction materials. These methods typically employ oxidizing agents such as halogenated compounds, hydrogen peroxide, ozone, peracetic acid, or combinations thereof. Halogenated compounds are effective sanitizers but are difficult to flush from the system and may leave biofilms intact. Compounds such as hydrogen peroxide, ozone, and peracetic acid oxidize bacteria and biofilms by forming reactive peroxides and free radicals (notably hydroxyl radicals). The short half-life of ozone in particular, and its limitation on achievable concentrations require that it be added continuously during the sanitization process. Hydrogen peroxide and ozone rapidly degrade to water and oxygen; peracetic acid degrades to acetic acid in the presence of UV light. In fact, ozone's ease of degradation to oxygen using 254-nm UV lights at use points allow it to be most effectively used on a continuous basis to provide continuously sanitizing conditions.

In-line UV light at a wavelength of 254 nm can also be used to continuously "sanitize" water circulating in the system, but these devices must be properly sized for the water flow. Such devices inactivate a high percentage (but not 100%) of microorganisms that flow through the device but cannot be used to directly control existing biofilm upstream or downstream of the device. However, when coupled with conventional thermal or chemical sanitization technologies or located immediately upstream of a microbially retentive filter, it is most effective and can prolong the interval between system sanitizations.

It is important to note that microorganisms in a well-developed biofilm can be extremely difficult to kill, even by aggressive oxidizing biocides. The less developed and therefore thinner the biofilm, the more effective the biocidal action. Therefore, optimal biocide control is achieved by frequent biocide use that does not allow significant biofilm development between treatments.

Sanitization steps require validation to demonstrate the capability of reducing and holding microbial contamination at acceptable levels. Validation of thermal methods should include a heat distribution study to demonstrate that sanitization temperatures are achieved throughout the system, including the body of use point valves. Validation of chemical methods require demonstrating adequate chemical concentrations throughout the system, exposure to all wetted surfaces, including the body of use point valves, and complete removal of the sanitant from the system at the completion of treatment. Methods validation for the detection and quantification of residues of the sanitant or its objectionable degradants is an essential part of the validation program. The frequency of sanitization should be supported by, if not triggered by, the results of system microbial monitoring. Conclusions derived from trend analysis of the microbiological data should be used as the alert mechanism for maintenance. The frequency of sanitization should be established in such a way that the system operates in a state of microbiological control and does not routinely exceed alert levels (see *Alert and Action Levels and Specifications*).

OPERATION, MAINTENANCE, AND CONTROL

A preventive maintenance program should be established to ensure that the water system remains in a state of control. The program should include (1) procedures for operating the system, (2) monitoring programs for critical quality attributes and operating conditions including calibration of critical instruments, (3) schedule for periodic sanitization, (4) preventive maintenance of components, and (5) control of changes to the mechanical system and to operating conditions.

Operating Procedures—Procedures for operating the water system and performing routine maintenance and corrective action should be written, and they should also define the point when action is required. The procedures should be well documented, detail the function of each job, assign who is responsible for performing the work, and describe how the job is to be conducted. The effectiveness of these procedures should be assessed during water system validation.

Monitoring Program—Critical quality attributes and operating parameters should be documented and monitored. The program may include a combination of in-line sensors or automated instruments (e.g., for TOC, conductivity, hardness, and chlorine), automated or manual documentation of operational parameters (such as flow rates or pressure drop across a carbon bed, filter, or RO unit), and laboratory tests (e.g., total microbial counts). The frequency of sampling, the requirement for evaluating test results, and the necessity for initiating corrective action should be included.

Sanitization—Depending on system design and the selected units of operation, routine periodic sanitization may be necessary to maintain the system in a state of microbial control. Technologies for sanitization are described above.

Preventive Maintenance—A preventive maintenance program should be in effect. The program should establish what preventive maintenance is to be performed, the frequency of maintenance work, and how the work should be documented.

Change Control—The mechanical configuration and operating conditions must be controlled. Proposed changes should be evaluated for their impact on the whole system. The need to requalify the system after changes are made should be determined. Following a decision to modify a water system, the affected drawings, manuals, and procedures should be revised.

SAMPLING CONSIDERATIONS

Water systems should be monitored at a frequency that is sufficient to ensure that the system is in control and continues to produce water of acceptable quality. Samples should be taken from representative locations within the processing and distribution system. Established sampling frequencies should be based on system validation data and should cover critical areas including unit operation sites. The sampling plan should take into consideration the desired attributes of the water being sampled. For example, systems for *Water for Injection* because of their more critical microbiological requirements, may require a more rigorous sampling frequency.

Analyses of water samples often serve two purposes: in-process control assessments and final quality control assessments. In-process control analyses are usually focused on the attributes of the water within the system. Quality control is primarily concerned with the attributes of the water delivered by the system to its various uses. The latter usually employs some sort of transfer device, often a flexible hose, to bridge the gap between the distribution system use-point valve and the actual location of water use. The issue of sample collection location and sampling procedure is often hotly debated because of the typically mixed use of the data

generated from the samples, for both in-process control and quality control. In these single sample and mixed data use situations, the worst-case scenario should be utilized. In other words, samples should be collected from use points using the same delivery devices, such as hoses, and procedures, such as preliminary hose or outlet flushing, as are employed by production from those use points. Where use points per se cannot be sampled, such as hard-piped connections to equipment, special sampling ports may be used. In all cases, the sample must represent as closely as possible the quality of the water used in production. If a point of use filter is employed, sampling of the water prior to and after the filter is needed because the filter will mask the microbial control achieved by the normal operating procedures of the system.

Samples containing chemical sanitizing agents require neutralization prior to microbiological analysis. Samples for microbiological analysis should be tested immediately, or suitably refrigerated to preserve the original microbial attributes until analysis can begin. Samples of flowing water are only indicative of the concentration of planktonic (free floating) microorganisms present in the system. Biofilm microorganisms (those attached to water system surfaces) are usually present in greater numbers and are the source of the planktonic population recovered from grab samples. Microorganisms in biofilms represent a continuous source of contamination and are difficult to directly sample and quantify. Consequently, the planktonic population is usually used as an indicator of system contamination levels and is the basis for system *Alert* and *Action Levels*. The consistent appearance of elevated planktonic levels is usually an indication of advanced biofilm development in need of remedial control. System control and sanitization are key in controlling biofilm formation and the consequent planktonic population.

Sampling for chemical analyses is also done for in-process control and for quality control purposes. However, unlike microbial analyses, chemical analyses can be and often are performed using on-line instrumentation. Such on-line testing has unequivocal in-process control purposes because it is not performed on the water delivered from the system. However, unlike microbial attributes, chemical attributes are usually not significantly degraded by hoses. Therefore, through verification testing, it may be possible to show that the chemical attributes detected by the on-line instrumentation (in-process testing) are equivalent to those detected at the ends of the use point hoses (quality control testing). This again creates a single sample and mixed data use scenario. It is far better to operate the instrumentation in a continuous mode, generating large volumes of in-process data, but only using a defined small sampling of that data for QC purposes. Examples of acceptable approaches include using highest values for a given period, highest time-weighted average for a given period (from fixed or rolling sub-periods), or values at a fixed daily time. Each approach has advantages and disadvantages relative to calculation complexity and reflection of continuous quality, so the user must decide which approach is most suitable or justifiable.

CHEMICAL CONSIDERATIONS

The chemical attributes of *Purified Water* and *Water for Injection* in effect prior to USP 23 were specified by a series of chemistry tests for various specific and nonspecific attributes with the intent of detecting chemical species indicative of incomplete or inadequate purification. While these methods could have been considered barely adequate to control the quality of these waters, they nevertheless stood the test of time. This was partly because the operation of water systems was, and still is, based on on-line conductivity measurements and specifications generally thought to preclude the failure of these archaic chemistry attribute tests.

USP moved away from these chemical attribute tests to contemporary analytical technologies for the bulk waters *Purified Water* and *Water for Injection*. The intent was to up-

grade the analytical technologies without tightening the quality requirements. The two contemporary analytical technologies employed were TOC and conductivity. The TOC test replaced the test for *Oxidizable substances* that primarily targeted organic contaminants. A multistaged *Conductivity* test which detects ionic (mostly inorganic) contaminants replaced, with the exception of the test for *Heavy metals*, all of the inorganic chemical tests (i.e., *Ammonia*, *Calcium*, *Carbon dioxide*, *Chloride*, *Sulfate*).

Replacing the heavy metals attribute was considered unnecessary because (a) the source water specifications (found in the NPDWR) for individual *Heavy metals* were tighter than the approximate limit of detection of the *Heavy metals* test for *USP XXII Water for Injection* and *Purified Water* (approximately 0.1 ppm), (b) contemporary water system construction materials do not leach heavy metal contaminants, and (c) test results for this attribute have uniformly been negative—there has not been a confirmed occurrence of a singular test failure (failure of only the *Heavy metals* test with all other attributes passing) since the current heavy metal drinking water standards have been in place. Nevertheless, since the presence of heavy metals in *Purified Water* or *Water for Injection* could have dire consequences, its absence should at least be documented during new water system commissioning and validation or through prior test results records.

Total solids and *pH* were the only tests not covered by conductivity testing. The test for *Total solids* was considered redundant because the nonselective tests of conductivity and TOC could detect most chemical species other than silica, which could remain undetected in its colloidal form. Colloidal silica in *Purified Water* and *Water for Injection* is easily removed by most water pretreatment steps and even if present in the water, constitutes no medical or functional hazard except under extreme and rare situations. In such extreme situations, other attribute extremes are also likely to be detected. It is, however, the user's responsibility to ensure fitness for use. If silica is a significant component in the source water, and the purification unit operations could be operated or fail and selectively allow silica to be released into the finished water (in the absence of co-contaminants

detectable by conductivity), then either silica-specific or a total solids type testing should be utilized to monitor and control this rare problem.

The *pH* attribute was eventually recognized to be redundant to the conductivity test (which included *pH* as an aspect of the test and specification); therefore, *pH* was dropped as a separate attribute test.

The rationale used by USP to establish its *Purified Water* and *Water for Injection* conductivity specifications took into consideration the conductivity contributed by the two least conductive former attributes of *Chloride* and *Ammonia*, thereby precluding their failure had those wet chemistry tests been performed. In essence, the *Stage 3* conductivity specifications (see *Water Conductivity, Bulk Water* (645)) were established from the sum of the conductivities of the limit concentrations of chloride ions (from pH 5.0 to 6.2) and ammonia ions (from pH 6.3 to 7.0), plus the unavoidable contribution of other conductivity-contributing ions from water (H^+ and OH^-), dissolved atmospheric CO_2 (as HCO_3^-), and an electro-balancing quantity of either Na^+ or Cl^- , depending on the pH-induced ionic imbalance (see *Table 1*). The *Stage 2* conductivity specification is the lowest value on this table, 2.1 $\mu S/cm$. The *Stage 1* specifications, designed primarily for on-line measurements, were derived essentially by summing the lowest values in the contributing ion columns for each of a series of tables similar to *Table 1*, created for each 5° increment between 0° and 100°. For example purposes, the italicized values in *Table 1*, the conductivity data table for 25°, were summed to yield a conservative value of 1.3 $\mu S/cm$, the *Stage 1* specification for a nontemperature compensated, nonatmosphere equilibrated water sample that actually had a measured temperature of 25° to 29°. Each 5° increment in the table was similarly treated to yield the individual values listed in the table of *Stage 1* specifications (see *Water Conductivity, Bulk Water* (645)).

As stated above, this rather radical change to utilizing a conductivity attribute as well as the inclusion of a TOC attribute allowed for on-line measurements. This was a major philosophical change and allowed major savings to be realized by industry. The TOC and conductivity tests can also

be performed “off-line” in the laboratories using collected samples, though sample collection tends to introduce opportunities for adventitious contamination that can cause false high readings. The collection of on-line data is not, however, without challenges. The continuous readings tend to create voluminous amounts of data where before only a single data point was available. As stated under *Sampling Considerations*, continuous in-process data is excellent for understanding how a water system performs during all of its various usage and maintenance events in real time, but is too much data for QC purposes. Therefore, a justifiable fraction or averaging of the data can be used that is still representative of the overall water quality being used.

Packaged/sterile waters present a particular dilemma relative to the attributes of conductivity and TOC. The package itself is the source of chemicals (inorganics and organics) that leach over time into the packaged water and can easily be detected by the conductivity and TOC tests. The irony of organic leaching from plastic packaging is that before the advent of bulk water TOC testing when the *Oxidizable substances* test was the only “organic purity” test for both bulk and packaged/sterile water monographs in *USP*, that test’s insensitivity to many of the organic leachables from plastic and elastomeric packaging materials was largely unrealized, allowing organic levels in packaged/sterile water to be quite high (possibly many times the TOC specification for bulk water). Similarly, glass containers can also leach inorganics, such as sodium, which are easily detected by conductivity, but poorly detected by the former wet chemistry attribute tests. Most of these leachables are considered harmless by current perceptions and standards at the rather significant concentrations present. Nevertheless, they effectively degrade the quality of the high-purity waters placed into these packaging systems. Some packaging materials contain more leachables than others and may not be as suitable for holding water and maintaining its purity.

The attributes of conductivity and TOC tend to reveal more about the packaging leachables than they do about the water’s original purity. These currently “allowed” leachables could render the sterile packaged versions of originally equivalent bulk water essentially unsuitable for many uses where the bulk waters are perfectly adequate.

Therefore, to better control the ionic packaging leachables, *Water Conductivity* <645> is divided into two sections. The first is titled *Bulk Water*, which applies to *Purified Water*, *Water for Injection*, *Water for Hemodialysis*, and *Pure Steam*, and includes the three-stage conductivity testing instructions and specifications. The second is titled *Sterile Water*, which applies to *Sterile Purified Water*, *Sterile Water for Injection*, *Sterile Water for Inhalation*, and *Sterile Water for Irrigation*. The *Sterile Water* section includes conductivity specifications similar to the *Stage 2* testing approach because it is intended as a laboratory test, and these sterile waters were made from bulk water that already complied with the three-stage conductivity test. In essence, packaging leachables are the primary target “analytes” of the conductivity specifications in the *Sterile Water* section of *Water Conductivity* <645>. The effect on potential leachables from different container sizes is the rationale for having two different specifications, one for small packages containing nominal volumes of 10 mL or less and another for larger packages. These conductivity specifications are harmonized with the *European Pharmacopoeia* conductivity specifications for *Sterile Water for Injection*. All monographed waters, except *Bacteriostatic Water for Injection*, have a conductivity specification that directs the user to either the *Bulk Water* or the *Sterile Water* section of *Water Conductivity* <645>. For the sterile packaged water monographs, this water conductivity specification replaces the redundant wet chemistry limit tests intended for inorganic contaminants that had previously been specified in these monographs.

Controlling the organic purity of these sterile packaged waters, particularly those in plastic packaging, is more challenging. Though the TOC test can better detect and therefore be better used to monitor and control these impurities

than the current *Oxidizable substances* test, the latter has many decades-old precedents and flexibility with the variety of packaging types and volumes applicable to these sterile packaged waters. Nevertheless, TOC testing of these currently allowed sterile, plastic-packaged waters reveals substantial levels of plastic-derived organic leachables that render the water perhaps orders of magnitude less organically pure than typically achieved with bulk waters. Therefore, usage of these packaged waters for analytical, manufacturing, and cleaning applications should only be exercised after suitability of the waters’ purity for the application has been assured.

MICROBIAL CONSIDERATIONS

The major exogenous source of microbial contamination of bulk pharmaceutical water is source or feed water. Feed water quality must, at a minimum, meet the quality attributes of Drinking Water for which the level of coliforms are regulated. A wide variety of other microorganisms, chiefly Gram-negative bacteria, may be present in the incoming water. These microorganisms may compromise subsequent purification steps. Examples of other potential exogenous sources of microbial contamination include unprotected vents, faulty air filters, ruptured rupture disks, backflow from contaminated outlets, unsanitized distribution system “openings” including routine component replacements, inspections, repairs, and expansions, inadequate drain and air-breaks, and replacement activated carbon, deionizer resins, and regenerant chemicals. In these situations, the exogenous contaminants may not be normal aquatic bacteria but rather microorganisms of soil or even human origin. The detection of nonaquatic microorganisms may be an indication of a system component failure, which should trigger investigations that will remediate their source. Sufficient care should be given to system design and maintenance in order to minimize microbial contamination from these exogenous sources.

Unit operations can be a major source of endogenous microbial contamination. Microorganisms present in feed water may adsorb to carbon bed, deionizer resins, filter membranes, and other unit operation surfaces and initiate the formation of a biofilm. In a high-purity water system, biofilm is an adaptive response by certain microorganisms to survive in this low nutrient environment. Downstream colonization can occur when microorganisms are shed from existing biofilm-colonized surfaces and carried to other areas of the water system. Microorganisms may also attach to suspended particles such as carbon bed fines or fractured resin particles. When the microorganisms become planktonic, they serve as a source of contamination to subsequent purification equipment (compromising its functionality) and to distribution systems.

Another source of endogenous microbial contamination is the distribution system itself. Microorganisms can colonize pipe surfaces, rough welds, badly aligned flanges, valves, and unidentified dead legs, where they proliferate, forming a biofilm. The smoothness and composition of the surface may affect the rate of initial microbial adsorption, but once adsorbed, biofilm development, unless otherwise inhibited by sanitizing conditions, will occur regardless of the surface. Once formed, the biofilm becomes a continuous source of microbial contamination.

ENDOTOXIN CONSIDERATIONS

Endotoxins are lipopolysaccharides found in and shed from the cell envelope that is external to the cell wall of Gram-negative bacteria. Gram-negative bacteria that form biofilms can become a source of endotoxins in pharmaceutical waters. Endotoxins may occur as clusters of lipopolysaccharide molecules associated with living microorganisms, fragments of dead microorganisms or the polysaccharide

slime surrounding biofilm bacteria, or as free molecules. The free form of endotoxins may be released from cell surfaces of the bacteria that colonize the water system, or from the feed water that may enter the water system. Because of the multiplicity of endotoxin sources in a water system, endotoxin quantitation in a water system is not a good indicator of the level of biofilm abundance within a water system.

Endotoxin levels may be minimized by controlling the introduction of free endotoxins and microorganisms in the feed water and minimizing microbial proliferation in the system. This may be accomplished through the normal exclusion or removal action afforded by various unit operations within the treatment system as well as through system sanitization. Other control methods include the use of ultrafilters or charge-modified filters, either in-line or at the point of use. The presence of endotoxins may be monitored as described in the general test chapter *Bacterial Endotoxins Test* (85).

MICROBIAL ENUMERATION CONSIDERATIONS

The objective of a water system microbiological monitoring program is to provide sufficient information to control and assess the microbiological quality of the water produced. Product quality requirements should dictate water quality specifications. An appropriate level of control may be maintained by using data trending techniques and, if necessary, limiting specific contraindicated microorganisms. Consequently, it may not be necessary to detect all of the microorganisms species present in a given sample. The monitoring program and methodology should indicate adverse trends and detect microorganisms that are potentially harmful to the finished product, process, or consumer. Final selection of method variables should be based on the individual requirements of the system being monitored.

It should be recognized that there is no single method that is capable of detecting all of the potential microbial contaminants of a water system. The methods used for microbial monitoring should be capable of isolating the numbers and types of organisms that have been deemed significant relative to in-process system control and product impact for each individual system. Several criteria should be considered when selecting a method to monitor the microbial content of a pharmaceutical water system. These include method sensitivity, range of organisms types or species recovered, sample processing throughput, incubation period, cost, and methodological complexity. An alternative consideration to the use of the classical "culture" approaches is a sophisticated instrumental or rapid test method that may yield more timely results. However, care must be exercised in selecting such an alternative approach to ensure that it has both sensitivity and correlation to classical culture approaches, which are generally considered the accepted standards for microbial enumeration.

Consideration should also be given to the timeliness of microbial enumeration testing after sample collection. The number of detectable planktonic bacteria in a sample collected in a scrupulously clean sample container will usually drop as time passes. The planktonic bacteria within the sample will tend to either die or to irretrievably adsorb to the container walls reducing the number of viable planktonic bacteria that can be withdrawn from the sample for testing. The opposite effect can also occur if the sample container is not scrupulously clean and contains a low concentration of some microbial nutrient that could promote microbial growth within the sample container. Because the number of recoverable bacteria in a sample can change positively or negatively over time after sample collection, it is best to test the samples as soon as possible after being collected. If it is not possible to test the sample within about 2 hours of collection, the sample should be held at refrigerated temperatures (2° to 8°) for a maximum of about 12 hours to maintain the microbial attributes until analysis. In situations

where even this is not possible (such as when using off-site contract laboratories), testing of these refrigerated samples should be performed within 48 hours after sample collection. In the delayed testing scenario, the recovered microbial levels may not be the same as would have been recovered had the testing been performed shortly after sample collection. Therefore, studies should be performed to determine the existence and acceptability of potential microbial enumeration aberrations caused by protracted testing delays.

The Classical Culture Approach

Classical culture approaches for microbial testing of water include but are not limited to pour plates, spread plates, membrane filtration, and most probable number (MPN) tests. These methods are generally easy to perform, are less expensive, and provide excellent sample processing throughput. Method sensitivity can be increased via the use of larger sample sizes. This strategy is used in the membrane filtration method. Culture approaches are further defined by the type of medium used in combination with the incubation temperature and duration. This combination should be selected according to the monitoring needs presented by a specific water system as well as its ability to recover the microorganisms of interest: those that could have a detrimental effect on the product or process uses as well as those that reflect the microbial control status of the system.

There are two basic forms of media available for traditional microbiological analysis: "high nutrient" and "low nutrient". High-nutrient media such as plate count agar (TGYA) and m-HPC agar (formerly m-SPC agar), are intended as general media for the isolation and enumeration of heterotrophic or "copiotrophic" bacteria. Low-nutrient media such as R2A agar and NWRI agar (HPCA), may be beneficial for isolating slow growing "oligotrophic" bacteria and bacteria that require lower levels of nutrients to grow optimally. Often some facultative oligotrophic bacteria are able to grow on high nutrient media and some facultative copiotrophic bacteria are able to grow on low-nutrient media, but this overlap is not complete. Low-nutrient and high-nutrient cultural approaches may be concurrently used, especially during the validation of a water system, as well as periodically thereafter. This concurrent testing could determine if any additional numbers or types of bacteria can be preferentially recovered by one of the approaches. If so, the impact of these additional isolates on system control and the end uses of the water could be assessed. Also, the efficacy of system controls and sanitization on these additional isolates could be assessed.

Duration and temperature of incubation are also critical aspects of a microbiological test method. Classical methodologies using high nutrient media are typically incubated at 30° to 35° for 48 to 72 hours. Because of the flora in certain water systems, incubation at lower temperatures (e.g., 20° to 25°) for longer periods (e.g., 5 to 7 days) can recover higher microbial counts when compared to classical methods. Low-nutrient media are designed for these lower temperature and longer incubation conditions (sometimes as long as 14 days to maximize recovery of very slow growing oligotrophs or sanitant injured microorganisms), but even high-nutrient media can sometimes increase their recovery with these longer and cooler incubation conditions. Whether or not a particular system needs to be monitored using high- or low-nutrient media with higher or lower incubation temperatures or shorter or longer incubation times should be determined during or prior to system validation and periodically reassessed as the microbial flora of a new water system gradually establish a steady state relative to its routine maintenance and sanitization procedures. The establishment of a "steady state" can take months or even years and can be perturbed by a change in use patterns, a change in routine and preventative maintenance or sanitiza-

tion procedures, and frequencies, or any type of system intrusion, such as for component replacement, removal, or addition. The decision to use longer incubation periods should be made after balancing the need for timely information and the type of corrective actions required when an alert or action level is exceeded with the ability to recover the microorganisms of interest.

The advantages gained by incubating for longer times, namely recovery of injured microorganisms, slow growers, or more fastidious microorganisms, should be balanced against the need to have a timely investigation and to take corrective action, as well as the ability of these microorganisms to detrimentally affect products or processes. In no case, however, should incubation at 30° to 35° be less than 48 hours or less than 96 hours at 20° to 25°.

Normally, the microorganisms that can thrive in extreme environments are best cultivated in the laboratory using conditions simulating the extreme environments from which they were taken. Therefore, thermophilic bacteria might be able to exist in the extreme environment of hot pharmaceutical water systems, and if so, could only be recovered and cultivated in the laboratory if similar thermal conditions were provided. Thermophilic aquatic microorganisms do exist in nature, but they typically derive their energy for growth from harnessing the energy from sunlight, from oxidation/reduction reactions of elements such as sulfur or iron, or indirectly from other microorganisms that do derive their energy from these processes. Such chemical/nutritional conditions do not exist in high purity water systems, whether ambient or hot. Therefore, it is generally considered pointless to search for thermophiles from hot pharmaceutical water systems owing to their inability to grow there.

The microorganisms that inhabit hot systems tend to be found in much cooler locations within these systems, for example, within use-point heat exchangers or transfer hoses. If this occurs, the kinds of microorganisms recovered are usually of the same types that might be expected from ambient water systems. Therefore, the mesophilic microbial cultivation conditions described later in this chapter are usually adequate for their recovery.

“Instrumental” Approaches

Examples of instrumental approaches include microscopic visual counting techniques (e.g., epifluorescence and immunofluorescence) and similar automated laser scanning approaches and radiometric, impedometric, and biochemically based methodologies. These methods all possess a variety of advantages and disadvantages. Advantages could be their precision and accuracy or their speed of test result availability as compared to the classical cultural approach. In general, instrument approaches often have a shorter lead time for obtaining results, which could facilitate timely system control. This advantage, however, is often counterbalanced by limited sample processing throughput due to extended sample collection time, costly and/or labor-intensive sample processing, or other instrument and sensitivity limitations.

Furthermore, instrumental approaches are typically destructive, precluding subsequent isolate manipulation for characterization purposes. Generally, some form of microbial isolate characterization, if not full identification, may be a required element of water system monitoring. Consequently, culturing approaches have traditionally been preferred over instrumental approaches because they offer a balance of desirable test attributes and post-test capabilities.

Suggested Methodologies

The following general methods were originally derived from *Standard Methods for the Examination of Water and Wastewater*, 17th Edition, American Public Health Association, Washington, DC 20005. Even though this publication has

undergone several revisions since its first citation in this chapter, the methods are still considered appropriate for establishing trends in the number of colony-forming units observed in the routine microbiological monitoring of pharmaceutical waters. It is recognized, however, that other combinations of media and incubation time and temperature may occasionally or even consistently result in higher numbers of colony-forming units being observed and/or different species being recovered.

The extended incubation periods that are usually required by some of the alternative methods available offer disadvantages that may outweigh the advantages of the higher counts that may be obtained. The somewhat higher baseline counts that might be observed using alternate cultural conditions would not necessarily have greater utility in detecting an excursion or a trend. In addition, some alternate cultural conditions using low-nutrient media tend to lead to the development of microbial colonies that are much less differentiated in colonial appearance, an attribute that microbiologists rely on when selecting representative microbial types for further characterization. It is also ironical that the nature of some of the slow growers and the extended incubation times needed for their development into visible colonies may also lead to those colonies being largely nonviable, which limits their further characterization and precludes their subculture and identification.

Methodologies that can be suggested as generally satisfactory for monitoring pharmaceutical water systems are as follows. However, it must be noted that these are not referee methods nor are they necessarily optimal for recovering microorganisms from all water systems. The users should determine through experimentation with various approaches which methodologies are best for monitoring their water systems for in-process control and quality control purposes as well as for recovering any contraindicated species they may have specified.

<i>Drinking Water:</i>	Pour Plate Method or Membrane Filtration Method ¹
	Sample Volume—1.0 mL minimum ² Growth Medium—Plate Count Agar ³ Incubation Time—48 to 72 hours minimum Incubation Temperature—30° to 35°
<i>Purified Water:</i>	Pour Plate Method or Membrane Filtration Method ¹

¹ A membrane filter with a rating of 0.45 μm is generally considered preferable even though the cellular width of some of the bacteria in the sample may be narrower than this. The efficiency of the filtration process still allows the retention of a very high percentage of these smaller cells and is adequate for this application. Filters with smaller ratings may be used if desired, but for a variety of reasons the ability of the retained cells to develop into visible colonies may be compromised, so count accuracy must be verified by a reference approach.

² When colony counts are low to undetectable using the indicated minimum sample volume, it is generally recognized that a larger sample volume should be tested in order to gain better assurance that the resulting colony count is more statistically representative. The sample volume to consider testing is dependent on the user's need to know (which is related to the established alert and action levels and the water system's microbial control capabilities) and the statistical reliability of the resulting colony count. In order to test a larger sample volume, it may be necessary to change testing techniques, e.g., changing from a pour plate to a membrane filtration approach. Nevertheless, in a very low to nil count scenario, a maximum sample volume of around 250 to 300 mL is usually considered a reasonable balance of sample collecting and processing ease and increased statistical reliability. However, when sample volumes larger than about 2 mL are needed, they can only be processed using the membrane filtration method.

³ Also known as Standard Methods Agar, Standard Methods Plate Count Agar, or TGYA, this medium contains tryptone (pancreatic digest of casein), glucose and yeast extract.

<i>Drinking Water:</i>	Pour Plate Method or Membrane Filtration Method ¹
	Sample Volume—1.0 mL minimum ² Growth Medium—Plate Count Agar ³ Incubation Time—48 to 72 hours minimum Incubation Temperature—30° to 35°
<i>Water for Injection:</i>	Membrane Filtration Method ¹
	Sample Volume—100 mL minimum ² Growth Medium—Plate Count Agar ³ Incubation Time—48 to 72 hours minimum Incubation Temperature—30°C to 35°C

IDENTIFICATION OF MICROORGANISMS

Identifying the isolates recovered from water monitoring methods may be important in instances where specific waterborne microorganisms may be detrimental to the products or processes in which the water is used. Microorganism information such as this may also be useful when identifying the source of microbial contamination in a product or process. Often a limited group of microorganisms is routinely recovered from a water system. After repeated recovery and characterization, an experienced microbiologist may become proficient at their identification based on only a few recognizable traits such as colonial morphology and staining characteristics. This may allow for a reduction in the number of identifications to representative colony types, or, with proper analyst qualification, may even allow testing short cuts to be taken for these microbial identifications.

ALERT AND ACTION LEVELS AND SPECIFICATIONS

Though the use of alert and action levels is most often associated with microbial data, they can be associated with any attribute. In pharmaceutical water systems, almost every quality attribute, other than microbial quality, can be very rapidly determined with near-real time results. These short-delay data can give immediate system performance feedback, serving as ongoing process control indicators. However, because some attributes may not continuously be monitored or have a long delay in data availability (like microbial monitoring data), properly established *Alert and Action Levels* can serve as an early warning or indication of a

potentially approaching quality shift occurring between or at the next periodic monitoring. In a validated water system, process controls should yield relatively constant and more than adequate values for these monitored attributes such that their *Alert and Action Levels* are infrequently broached.

As process control indicators, alert and action levels are designed to allow remedial action to occur that will prevent a system from deviating completely out of control and producing water unfit for its intended use. This "intended use" minimum quality is sometimes referred to as a "specification" or "limit". In the opening paragraphs of this chapter, rationale was presented for no microbial specifications being included within the body of the bulk water (*Purified Water* and *Water for Injection*) monographs. This does not mean that the user should not have microbial specifications for these waters. To the contrary, in most situations such specifications should be established by the user. The microbial specification should reflect the maximum microbial level at which the water is still fit for use without compromising the quality needs of the process or product where the water is used. Because water from a given system may have many uses, the most stringent of these uses should be used to establish this specification.

Where appropriate, a microbial specification could be qualitative as well as quantitative. In other words, the number of total microorganisms may be as important as the number of a specific microorganism or even the absence of a specific microorganism. Microorganisms that are known to be problematic could include opportunistic or overt pathogens, nonpathogenic indicators of potentially undetected pathogens, or microorganisms known to compromise a process or product, such as by being resistant to a preservative or able to proliferate in or degrade a product. These microorganisms comprise an often ill-defined group referred to as "objectionable microorganisms". Because objectionable is a term relative to the water's use, the list of microorganisms in such a group should be tailored to those species with the potential to be present and problematic. Their negative impact is most often demonstrated when they are present in high numbers, but depending on the species, an allowable level may exist, below which they may not be considered objectionable.

As stated above, alert and action levels for a given process control attribute are used to help maintain system control and avoid exceeding the pass/fail specification for that attribute. Alert and action levels may be both quantitative and qualitative. They may involve levels of total microbial counts or recoveries of specific microorganisms. Alert levels are events or levels that, when they occur or are exceeded, indicate that a process may have drifted from its normal operating condition. Alert level excursions constitute a warning and do not necessarily require a corrective action. However, alert level excursions usually lead to the alerting of personnel involved in water system operation as well as QA. Alert level excursions may also lead to additional monitoring with more intense scrutiny of resulting and neighboring data as well as other process indicators. Action levels are events or higher levels that, when they occur or are exceeded, indicate that a process is probably drifting from its normal operating range. Examples of kinds of action level "events" include exceeding alert levels repeatedly; or in multiple simultaneous locations, a single occurrence of exceeding a higher microbial level; or the individual or repeated recovery of specific objectionable microorganisms. Exceeding an action level should lead to immediate notification of both QA and personnel involved in water system operations so that corrective actions can immediately be taken to bring the process back into its normal operating range. Such remedial actions should also include efforts to understand and eliminate or at least reduce the incidence of a future occurrence. A root cause investigation may be necessary to devise an effective preventative action strategy. Depending on the nature of the action level excursion, it may also be necessary to evaluate its impact on the water uses during that time.

Impact evaluations may include delineation of affected batches and additional or more extensive product testing. It may also involve experimental product challenges.

Alert and action levels should be derived from an evaluation of historic monitoring data called a trend analysis. Other guidelines on approaches that may be used, ranging from “inspectional” to statistical evaluation of the historical data have been published. The ultimate goal is to understand the normal variability of the data during what is considered a typical operational period. Then, trigger points or levels can be established that will signal when future data may be approaching (alert level) or exceeding (action level) the boundaries of that “normal variability”. Such alert and action levels are based on the control capability of the system as it was being maintained and controlled during that historic period of typical control.

In new water systems where there is very limited or no historic data from which to derive data trends, it is common to simply establish initial alert and action levels based on a combination of equipment design capabilities but below the process and product specifications where water is used. It is also common, especially for ambient water systems, to microbiologically “mature” over the first year of use. By the end of this period, a relatively steady state microbial population (microorganism types and levels) will have been allowed or promoted to develop as a result of the collective effects of routine system maintenance and operation, including the frequency of unit operation rebeddings, backwashings, regenerations, and sanitizations. This microbial population will typically be higher than was seen when the water system was new, so it should be expected that the data trends (and the resulting alert and action levels) will increase over this “maturation” period and eventually level off.

A water system should be designed so that performance-based alert and action levels are well below water specifications. With poorly designed or maintained water systems, the system owner may find that initial new system microbial levels were acceptable for the water uses and specifications, but the mature levels are not. This is a serious situation, which if not correctable with more frequent system maintenance and sanitization, may require expensive water system renovation or even replacement. Therefore, it cannot be overemphasized that water systems should be designed for ease of microbial control, so that when monitored against alert and action levels, and maintained accordingly, the water continuously meets all applicable specifications.

An action level should not be established at a level equivalent to the specification. This leaves no room for remedial system maintenance that could avoid a specification excursion. Exceeding a specification is a far more serious event than an action level excursion. A specification excursion may trigger an extensive finished product impact investigation, substantial remedial actions within the water system that may include a complete shutdown, and possibly even product rejection.

Another scenario to be avoided is the establishment of an arbitrarily high and usually nonperformance based action level. Such unrealistic action levels deprive users of meaningful indicator values that could trigger remedial system maintenance. Unrealistically high action levels allow systems to grow well out of control before action is taken, when their intent should be to catch a system imbalance before it goes wildly out of control.

Because alert and action levels should be based on actual system performance, and the system performance data are generated by a given test method, it follows that those alert and action levels should be valid only for test results generated by the same test method. It is invalid to apply alert and action level criteria to test results generated by a different test method. The two test methods may not equivalently recover microorganisms from the same water samples. Similarly invalid is the use of trend data to derive alert and action levels for one water system, but applying those alert and action levels to a different water system. Alert and action levels are water system and test method specific.

Nevertheless, there are certain maximum microbial levels above which action levels should never be established. Water systems with these levels should unarguably be considered out of control. Using the microbial enumeration methodologies suggested above, generally considered maximum action levels are 100 cfu per mL for *Purified Water* and 10 cfu per 100 mL for *Water for Injection*. However, if a given water system controls microorganisms much more tightly than these levels, appropriate alert and action levels should be established from these tighter control levels so that they can truly indicate when water systems may be starting to trend out of control. These in-process microbial control parameters should be established well below the user-defined microbial specifications that delineate the water's fitness for use.

Special consideration is needed for establishing maximum microbial action levels for *Drinking Water* because the water is often delivered to the facility in a condition over which the user has little control. High microbial levels in *Drinking Water* may be indicative of a municipal water system upset, broken water main, or inadequate disinfection, and therefore, potential contamination with objectionable microorganisms. Using the suggested microbial enumeration methodology, a reasonable maximum action level for *Drinking Water* is 500 cfu per mL. Considering the potential concern for objectionable microorganisms raised by such high microbial levels in the feedwater, informing the municipality of the problem so they may begin corrective actions should be an immediate first step. In-house remedial actions may or may not also be needed, but could include performing additional coliform testing on the incoming water and pre-treating the water with either additional chlorination or UV light irradiation or filtration or a combination of approaches.

(1235) VACCINES FOR HUMAN USE—GENERAL CONSIDERATIONS

INTRODUCTION

Vaccines have been used for centuries to immunize individuals against pathogenic organisms with the goal of preventing the associated disease. Vaccines are biological products that contain antigens capable of inducing a specific and active acquired immune response in the body. Antigens present in vaccines are processed by specialized cells in the body's immune system, resulting in the development of blood proteins known as antibodies (i.e., humoral immunity) or specialized lymphocytes (i.e., cell-mediated immunity) or both. Therefore immune responses may be antibody mediated, cell mediated, or both. Thus, antigens are critical for vaccine function and generally consist of a portion of the pathogenic organism, or an attenuated form of the whole microorganism. In the case of DNA-based vaccines (currently under development), the vaccine would contain nucleotide sequences (genetic material) that encode microbial antigens.

Examples of types of licensed vaccines appear in *Appendix 1*. A current list of vaccines licensed in the United States is posted at www.fda.gov/cber/.

Vaccines can be of various types, depending on their design and processes involved in their manufacture. Vaccines for human use may contain whole killed or attenuated organisms (e.g., bacteria or viruses) or contain antigens de-

rived from portions of a pathogen, either by partitioning and purification or derived using recombinant technology (Table 1). Some polysaccharide vaccines are conjugated to a carrier in order to enhance their immune response.

Modified toxins

^a Live attenuated bacterial or viral vaccines are weakened (attenuated) forms of a pathogen. They contain antigens that are similar to disease-causing microbes. They may be derived from the pathogen itself, or from a different organism that contains antigens that cross-react with the virulent microbe (e.g., vaccinia and variola).

^b Inactivated bacterial and viral vaccines are produced by growing cells of disease-causing bacteria or viruses in cell substrates and subsequently inactivating them to prevent replication in the recipient.

^c Inactivated/killed whole-cell or virus vaccines consist of the entire microorganisms after they have been inactivated. These preparations may or may not be partially or completely purified.

^d Recombinant protein viral and bacterial vaccines are derived from host cells that have been transformed with expression vectors that carry genes that encode antigenic material from infectious agents. The expression cells are grown in bioreactors to produce the recombinant antigenic material.

^e Subunit vaccines are extracts from inactivated/killed viruses or bacteria. Subunit-type vaccines generally undergo some degree of purification.

In addition to antigen(s), vaccines may contain several other components, such as adjuvants that enhance the immune response to the vaccine antigen, preservatives to prevent bacterial or fungal contamination of multiple-dose vials, or other excipients needed for pharmaceutical manufacturing or vaccine stabilization. Residual components from the manufacturing process also may be present in vaccine preparations. Examples of these categories are listed in Table 2.

Different vaccine antigens are often combined in one final formulation in order to elicit immunity against multiple diseases and to reduce the number of separate administrations needed to achieve immunity to the various vaccine antigens.

Despite the multiple forms vaccines may take, several common features characterize the manufacture and testing of vaccines. This chapter focuses on commonalities throughout the manufacturing process, from raw material qualifications to final release tests.

Regulations and Standards

Vaccines are regulated by FDA as biological products. The general requirements are listed in national laws and international guidances. For the U.S., national requirements are codified in 21 CFR, the 200 and 600 sections, with additional recommendations available in FDA *Points to Consider* and *Guidance* documents (www.fda.gov). International guidances are available from the International Conference on Harmonization (ICH) (www.ich.org; see *Appendix 2*) and the World Health Organization. New methodologies are continually being developed and validated and will be included in *USP* as they become available. Reference standards are available from USP and FDA.

OVERALL MANUFACTURING PLAN

When considering the overall plan for manufacturing a vaccine, manufacturers need to consider the following factors:

- Physical facilities;
- Raw materials and process aids;
- Actual manufacturing process, including
 - a. initial process (production of virus/bacteria and recombinant materials);
 - b. downstream processes (purification or chemical modification, if applicable);
- Antigen modifications such as conjugation or toxoiding;
- Storage of process intermediates and final bulk;
- In-process and final product testing regimens and control schemes;
- Addition of adjuvants, if applicable;
- Formulation and filling;
- Container–closure system; and
- Stability program that supports the dating period of the product.

Quality systems are needed to support the following manufacturing process development: specifications for raw materials, process intermediates, and final product; change control; and failure investigations and complaints. All of these elements are important in the life cycle of the vaccine product.

The overall goal of a comprehensive manufacturing program is to consistently produce a vaccine that is safe and effective. Concurrently with clinical development of the vaccine, the manufacturing process is refined and the process and testing methods are validated for consistency. This includes systems to control changes to the process or inputs. Manufacturers should expect that changes will be required during the vaccine’s manufacturing life cycle, and manufacturers necessarily will use data from development and routine manufacturing to assess the process as well as proposed changes. The manufacturers should adopt systems that continually evaluate all aspects of manufacturing to identify unanticipated changes in vaccine quality and to assess them as quickly as possible.

Manufacturing Facilities and Systems

Manufacturers should have a general layout of manufacturing facilities, including diagrams that show the following: flow of raw materials and process inputs; movement of

product, intermediates, waste streams, and personnel; and air flows and pressurization levels. These diagrams assist in minimizing the risk of potential product contamination from various sources. These sources can include cross-contamination from other products, contamination from different batches of the same product, and extraneous contamination from microorganisms and personnel. Evaluation of the flow diagrams can assist with strategies for development of engineering controls, personnel procedures, and monitoring systems to enable compliance with Good Manufacturing Practices (GMPs). Analysis of potential risks may also provide insights about what information should be recorded in batch documentation to facilitate consistent manufacture and also to facilitate failure investigations. Together, physical facilities, procedures, personnel, training, and quality systems make up the GMP environment in which a vaccine will be produced.

Manufacturing Process

The manufacturing process includes process inputs such as raw materials and processing aids and unit operations comprising both the initial and downstream processing steps. A process flow map for the manufacturing process is useful and assists in validation of the manufacturing process. This map shows all unit operations, the inputs to each operation, and the outputs to subsequent manufacturing steps. Analytical testing done at relevant steps and the specifications required to proceed to the next stage of processing may be added to the map. A process map also supports a processing space to facilitate a rugged process, i.e., one based on suitable characterization studies to establish boundaries within which manufacturing can occur to promote unchanged safety and efficacy outcomes.

The process flow map should include all steps from making the seed/cell bank (described below) to formulation and filling of the final product. The validation strategy should include the steps that require validation, along with identification of the process space, associated critical process parameters (CPP), and critical quality attributes (CQA). The critical process parameters are those that directly affect core quality attributes needed to successfully manufacture a batch of product. Some manufacturers identify other processing parameters that are important for processing but do not affect critical quality attributes. These important but noncritical factors help identify the process development space, can contribute to the development of a rugged process, or can be useful when the company assesses processing deviations. The concepts of quality by design and exploration of the process space are relatively new to the biologics/vaccine industry but are becoming considerations for the overall development-planning process.

Manufacturing Surveillance

Manufacturing surveillance is the continual observation of how the process and the resulting product are performing. This section is not exhaustive; rather, the points raised here outline the types of considerations recommended for a manufacturer during development of a vaccine. Manufacturing surveillance includes the following:

- Periodic review of the performance of the manufacturing process;
- Analytical assays;
- Stability programs;
- Product complaints;
- Adverse event reports;
- Product failure investigations;
- Atypical or deviation events.

Taken as a whole, these activities allow a manufacturer to assess the state of the process and product and to evaluate which, if any, operations need to be modified. These same systems also provide a surveillance matrix to evaluate changes. In any of these programs it is also valuable to de-

velop additional characterization assays that are not used for process intermediate or product release purposes but may be used for further evaluation when additional information is needed or desired. These additional assays for characterization are often based on different underlying analytical procedures to provide different ways to evaluate materials.

Routine surveillance processes are increasingly implemented to attempt to detect changes in processes before any critical quality attributes are adversely affected. Not all vaccine processes can be characterized to the same extent or level (e.g., a live virus vaccine vs. a recombinant protein vaccine), and statistical tools are often used to determine alert or action levels in surveillance programs. Exceeding these levels requires the manufacturer to evaluate the situation but does not necessarily signal product failure.

GMP manufacturing entails facility design, process development, quality systems, and manufacturing surveillance. Together these systems help the manufacturer to control the production of a vaccine. As noted, many types of vaccine are marketed, and each has its unique features and therefore requires different plans for each of the steps mentioned in this section.

SEED LOT SYSTEMS

Seed lots are the stocks of specific strains of bacteria, viruses, or biotechnology-engineered cells used to express vaccine antigens. All seed lots should be documented in terms of their isolation, derivation (or construction, in the case of recombinant vector or engineered cells), and passage history. The purpose of a seed-lot system, which typically includes master and working stock seeds, and associated master and working cell banks, is to help ensure the consistency of vaccine manufacturing. The use of master and working seed lots provides a method to limit the replication of the seed and to minimize the possibility of genetic variation.

A master seed lot is a physically homogeneous preparation derived from an original seed processed at one time and passaged for a limited number of times. The master seed lot is characterized for its biological, biochemical and genetic characteristics, and to ensure its purity, its freedom from adventitious agents, and its clinical ability to produce an effective vaccine.

Cultures from the working seed lot should have the same characteristics as the master seed lot from which they are derived. For influenza vaccines, which may be reformulated with new virus antigens each year, certified seed lots can be obtained from national regulatory agencies.

A working seed lot is derived from the master seed within a limited number of passages. The working seed is tested to ensure its purity, freedom from adventitious agents, and biochemical properties. The working seed is used for production of vaccine without intervening passages.

Bacterial Vaccine Seed Lot System

In the bacterial seed lot system, a master seed is subcultured to produce a working seed one passage beyond the master seed. An aliquot of the working seed is then expanded to produce a vaccine lot. The strain(s) used for the master seed lots are identified by historical records that include information about their origin. Information about the bacterial seed lot system should include source, passage history, and raw materials to which it was exposed, with specific emphasis on raw materials of ruminant origin. Seeds should be stored at an appropriate temperature in more than one location within a facility or at a distant site in order to decrease catastrophic risk.

Identity tests may include inoculation onto suitable biochemical media, Gram stains, genotype, and serological identification with suitable specific antisera. Special tests

may be added, for example, to show culture viability but also lack of virulence.

Purity of the bacterial strains used for seed lots is verified by methods of suitable sensitivity to ensure that no adventitious agents are present. These purity tests often are performed in the presence of the seed under conditions where growth is inhibited by the presence or the absence of specific nutrients. Streaking can also be used to show that the cultured seed is a pure culture.

Viral Vaccine Seed Lot System

The derivation and passage history of viral seeds should be recorded in detail. Any manipulation of the viral phenotype (e.g., cold adaptation, development of temperature sensitivity, or attenuation of virulence) or intentional genetic manipulations (e.g., reassortment or recombination) should be documented.

These viral seeds are commonly differentiated into a master viral seed and working viral seeds or working viral stock. Viral seeds should be stored at cryogenic temperatures to promote stability and in more than one location within a facility or at a distant site to decrease catastrophic risk. Manufacturers should assess the following characteristics of the viral seed stock:

- Growth characteristics on the intended production cell substrate;
- Tissue tropism;
- Genetic markers;
- Identity (for recombinant vectors);
- Viability during storage;
- Genetic stability through production;
- Attenuation properties;
- Purity;
- Absence of adventitious agents. If attenuation or derivation is achieved by passage through different species, the viral seed should be assessed for absence of adventitious agents common to those species.

The master viral seed should be extensively characterized to demonstrate the stability of genotype and phenotype for a number of passages beyond the level used in production. Generally, during assessment of genetic stability, a master seed undergoes a minimum of five passes beyond the passage that will produce the final vaccine.

Tests should be performed for identity (e.g., sequencing the entire virus or a portion of it), adventitious agents, viral phenotype, genetic stability, and, if applicable, agents that might be present in the seed as a result of its passage history. Viral phenotype can be assessed further for tissue tropism, attenuation properties, and temperature sensitivity. Not all of these tests may be necessary for every viral seed strain.

In some cases the viral seeds may have a broad host range and therefore may require neutralization of the vaccine virus before they are tested for adventitious agent(s). If possible, testing for adventitious agents should be done without neutralization in order to avoid an antiserum that may inadvertently neutralize an adventitious agent present in the seed. Sometimes it is not possible to effectively neutralize a viral seed, and in such cases alternative strategies can be used. For example, the test can be performed in a cell substrate that does not permit replication by the vaccine virus. However, such a substitution of the substrate cell may compromise the test's sensitivity for detection of other adventitious agents. Therefore, the tests may be supplemented with use of polymerase chain reaction (PCR) assays.

Assessment of neurovirulence may be appropriate if the virus is known to be neurotropic. Manufacturers should consult with regulators about appropriate animal models, methods, and scoring systems for this assessment before they initiate such studies. For viruses that are neurovirulent or may revert to neurovirulence (e.g., polioviruses), it may be necessary to assess neurovirulence beyond the master seed.

If the master viral seed is well characterized, the working viral seed may not require extensive characterization. For example, it may not be necessary to repeat testing for all the relevant viruses from the derivation history.

Systems for Biotechnology-Engineered Vaccines

For a vaccine produced via a biotechnology-engineered cell-expression system, a master seed lot or a master cell bank will be established during product development. The seed lot or cell banks should be homogenous, which is often accomplished by limiting dilutions. The seed lot or cell bank system should be characterized in a manner analogous to that used for the cell substrate discussed in the next section, and additional tests can be used to demonstrate the genetic stability of the expression system.

FERMENTATION AND CELL CULTURE MEDIA

A medium is the material in which an organism is grown and amplified in quantity to produce mass material for vaccine production. Its composition is diverse and depends on the cell types that the medium supports, ranging from well-defined chemical media to chemically undefined media that contain natural components such as sera from animal origin (see *Bovine Serum* (1024)). Culture media should be suitable for their intended purpose and should be free from adventitious agents and known undesirable components such as toxins, allergens, and similar compounds. If undefined ingredients are necessary, the amount should be kept below levels that are demonstrated to be safe for the final product.

Fermentation Media for Bacterial Growth

The nutrients consist of materials like proteins, sugars, inorganic trace elements, amino acids, and vitamins needed for bacterial growth. The protein component may be as simple as free casein (milk protein), or it can be as complex as extracts from bacterial, plant, or animal sources. Any fermentation nutrients of animal origin are sourced carefully and tested for adventitious agents. The composition of a medium is often customized to optimize product quality attributes. Medium components that are known to cause allergic reactions should be avoided.

Media for Cell Culture for Viral Vaccines

The types and composition of media used for isolation and all subsequent culture of components of viral vaccines need to be recorded in detail. Chemically defined media without materials of animal origin are preferred. The medium should be tested for sterility and suitability for the cells used in product production. If materials of animal origin are used, they are assessed for freedom from adventitious agents. If human albumin is used in a U.S.-licensed vaccine, it must be licensed by FDA. The final product should be within specified limits of residual medium components such as serum, antibiotics, selection agents or reagents added for growth enhancement.

Media for Biotechnology-Engineered Cells

The requirement for media used for the fermentation and propagation of biotechnology-engineered cells is the same as that noted above for bacterial fermentation and cell culture growth.

PROPAGATION AND HARVEST

The propagation and harvest phases follow the manufacturing process from the initiation of cell growth in the working cell bank to the separation of the crude drug substance. In addition, in these manufacturing process steps, raw materials, media, and solutions should be qualified for their intended use. Batch numbers should be clearly assigned as needed, and the relationship between component harvests and batches of individual drug substances should be recorded clearly.

Propagation and Harvest for Bacterial Vaccines

Propagation of bacteria for bacterial vaccines is performed under specified conditions for the inoculum preparation and the fermentation phases. In-process monitoring and testing should be conducted for quality assurance. All controls and testing performed after production (e.g., purity, viability, antigen yield, and phenotypic identity) should be documented. The first step of drug-substance recovery is harvesting from the bioreactor. A variety of equipment is available, and the process equipment used depends on the nature of the process. Procedures should be established to ensure containment and prevention of contamination during harvesting and to monitor bioburden (including acceptance criteria) or sterility. The storage conditions and the stability time limit for the harvest material should be described. For most bacterial vaccines, an inactivation step is necessary. Personnel involved in bacterial inactivation should consider the following: how cell culture purity is verified after inactivation, whether culture purity should be defined before inactivation, choice of the inactivation agent, and validation of the procedure(s).

Propagation and Harvest for Viral Vaccines

The manufacturing of viral vaccines using eukaryotic cell culture includes a two-phase production process. The first is the expansion of the cell cultures used as a substrate for viral replication. The second phase includes the initial virus infection and subsequent replication and virus production.

Cell Substrate Growth Phase—The cell substrate expansion process for viral production is the phase designed to prepare the cells in a physiological state appropriate to sustain virus growth. Cell substrates often require complex animal-derived supplements such as serum. The source and testing requirements of bovine serum are subject to regulatory requirements (see *Bovine Serum* (1024)).

Virus Production Phase—Relatively few cell types have been used as substrates in U.S.-licensed viral vaccines, but these include primary cells (e.g., certain cells derived from monkey, chick, or mouse tissue), diploid cell lines (e.g., WI-38, MRC-5, or FRhL-2), and continuous cell lines (e.g., Vero). Vaccine manufacturers have optimized nutrient requirements, growth factors, and serum concentration to support robust growth and strong virus productivity for these cell lines.

PURIFICATION

The objective of the purification steps is to remove as much as possible of the impurities in the initial harvest and to maximize the purity of the final vaccine product. Process residuals may consist of materials from the culture medium and/or cellular components. Purification procedures should be optimized and validated. When applicable, viral clearance steps (viral removal or inactivation) should be included and validated using relevant model viruses. Special considerations are observed depending on the types of vaccines and production system used, as discussed below.

Bacterial Fermentation

Bacterial fermentations are typically highly productive and yield large amounts of biomass. For bacterial subunit products or recombinant components expressed by bacteria, fermentation can produce very high concentrations of the desired active ingredient. Manufacturers should initiate culture purity testing before further processing.

Live Bacterial Vaccines—Live bacterial vaccines such as *Bacillus Calmette-Guérin* (BCG) and *Salmonella typhi* Ty21a are relatively fragile as pharmaceutical products and therefore tolerate only fairly gentle purification approaches. If osmotic and shear forces are constrained, then the integrity of the bacteria usually can be maintained.

Inactivated Bacterial Vaccines—At present no inactivated whole-cell bacterial vaccines are licensed for use in the U.S.

Purified Bacterial Antigens—Purification of bacterial components (e.g., proteins, toxins, and polysaccharides) generally requires cell disruption. More selective purification methods can be used to remove culture media and bacterial impurities and to achieve high purity of the target bacterial component.

Biotechnology-Engineered Cells

Of special concern in the purification of recombinant-derived vaccine components is the issue of residual host cell components that could produce an adverse immunogenic response in patients. This response could be exacerbated by the presence of vaccine adjuvants.

Recombinant Virus-Like Particles (VLP)—Formation of VLPs can coincidentally result in incorporation of host cell components (e.g., DNA) into the quaternary structure of the molecular assembly, resulting in a class of impurities that has a tight association with the active pharmaceutical ingredient. As a result, modern approaches to VLP production in some cases include a disassembly step that dissociates impurities from the viral proteins. This procedure is followed by a reassembly step that reforms the VLPs in the absence of the host components. Liquid-phase extractions and chromatographic procedures can be used to provide high-purity components for use in vaccine products with no substantial risk of carrying over significant residual host components.

Viral Vaccines Derived from Cell Culture

Viral Vaccines Derived from Continuous Cell Lines—If a continuous cell line (e.g., Vero) is used for vaccine production, a validated filtration step is necessary to separate virus from intact cells. The quantity and size of any residual host cell DNA also should be determined (see general information chapter *Nucleic Acid-Based Techniques—Approaches for Detecting Trace Nucleic Acids (Residual DNA Testing)* (1130)). Currently, 10 ng of host cell DNA is permitted per dose of a parenterally administered vaccine, and regulatory agencies continue to consider on a case-by-case basis the level of risk posed by host cell DNA for vaccines that are administered by other routes (e.g., nasal or oral). Multiple purification methods to reduce the size and amount of residual host-cell DNA present in the vaccine are desirable and include steps such as treatment with DNase, diafiltration, ultrafiltration, and column chromatography.

Viral Vaccines Derived from Human Diploid Cell Culture—FDA has licensed several vaccines made using human diploid cells. The two most commonly used diploid cell lines are MRC-5 and WI-38, both of which are derived from human embryonic cells and have the normal diploid number of human chromosomes. They are widely used to manufacture vaccines because they have been shown to have no tumorigenic or oncogenic potential and have been

shown to be susceptible to a wide range of human viruses. However, unlike continuous cell lines that can be passaged indefinitely, human diploid cell lines are capable of attaining only a certain number of population doublings, after which they experience a rapid decline in their ability to proliferate. This issue is managed by freezing multiple aliquots of master and working cell banks.

Viral Vaccines Derived from Primary Cell Culture—Like diploid cells, primary cells normally are not tumorigenic or oncogenic. However, when primary cells are used to manufacture live vaccines, the donor animals from which the primary cells are obtained are extensively tested for a variety of pathogens before being used. For example, chicken flocks used to prepare chicken embryo kidney cells undergo extensive serological testing for adventitious agents before the flock can be used to prepare the cells. Some of these tests are described in the Code of Federal Regulations (CFR, see the sections listed in *Appendix 2*) and the USP general information chapter *Virology Test Methods* (1237).

Viral Vaccines Derived from Chicken Eggs

The embryonated chicken egg is a highly productive growth substrate for certain viruses, such as those used to make vaccines for yellow fever and several influenza vaccines. In the case of influenza vaccines, vaccine virus is harvested from egg allantoic fluid. In the case of yellow fever vaccine, the vaccine virus is harvested from embryo tissues. Therefore, residual egg or embryo components are special considerations in vaccine purification.

Egg-based vaccine production, like all biomass expansions, requires care and quality control of the virus seed lots and egg substrates to avoid contamination with other organisms.

Live Attenuated Virus Vaccines—Viruses for live vaccines (e.g., yellow fever or live influenza) are produced using Specific Pathogen-Free (SPF) eggs. These eggs are produced by chicken flocks that are regularly screened for avian pathogens (e.g., avian leukosis virus) and are maintained using appropriate animal husbandry practices. To preserve the infectivity and antigenic integrity of the vaccine viruses while removing egg-derived components, relatively simple, mild methods (e.g., zonal sucrose gradient centrifugation and diafiltration) are used for vaccine virus concentration, purification, and buffer exchange.

Inactivated Whole Virus Vaccines—Viruses for inactivated vaccines can be produced using non-SPF eggs because of required chemical inactivation steps in the manufacturing process. Because the vaccine virus needs to be retained intact while removing egg-derived components and inactivating chemicals, relatively mild purification and concentration methods (e.g., zonal sucrose gradient centrifugation) are used. If chemical agents are used in the process, they should be minimized in the final product to below prespecified levels.

Split Virus and Purified Subunit Vaccines—Viruses for split virus and purified subunit influenza vaccines are produced in non-SPF embryonated eggs. Inactivation and purification of vaccine viruses are achieved by chemical treatment (e.g., formaldehyde or β -propiolactone) and zonal sucrose gradient centrifugation, respectively. Split virus vaccines are prepared by disruption of vaccine virus particles using a detergent (e.g., sodium deoxycholate) that preserves antigenic integrity.

INTERMEDIATES

Intermediates are defined here as the unformulated active (immunogenic) drug substances that are processed before final formulation and can be stored for long periods of time before further processing. These intermediates can be stored and should be included in a formal stability program. Exam-

ples of intermediates include bulk polysaccharides, purified recombinant proteins (concentrates), and conjugates.

Production of Intermediates

Intermediates are manufactured from starting materials by one or a combination of different processes (e.g., fermentation, cultivation, isolation, or synthesis). Subsequent steps of the procedure involve preparation, characterization, and purification, eventually resulting in the drug substance. Quality systems documents are adopted for production and all applicable information should be recorded in a controlled document (i.e., a batch record). When applicable, stability studies and release tests should be performed before proceeding to the next steps (see below).

Tests for Intermediates

The quality attributes of the intermediate are commonly tested in conjunction with further processing. Characterization beyond release testing should be considered. Characterization methods can use appropriately qualified procedures. Some tests are routinely performed before the intermediates are converted to the final bulk, depending on individual vaccines.

If intermediates need to be stored and/or subsequently shipped to a different location for further processing, the stability of these materials should be demonstrated. Stability tests can be a combination of both physicochemical analysis and biological assays.

FINAL BULK

Final bulk is the bulk drug product that contains the drug substance(s), excipients, and other ingredients at desired concentrations and is ready for filling into individual containers.

Production of Final Bulk

Appropriately controlled amounts of all ingredients are blended to uniformity to produce the final bulk. The processing may include one or more steps such as buffer exchange and addition of diluents, bulking agent, stabilizing excipients, adjuvants, and preservatives. Final bulk may be prepared aseptically or processing may include a sterilization step.

Tests for Final Bulk

The quality attributes of the final bulk should be tested. Appropriate testing should be performed with respect to identity, purity, potency, sterility (see *Sterility Tests* (71)), and antimicrobial effectiveness (see *Antimicrobial Effectiveness Testing* (51)). Tests demonstrating safety, if applicable, are performed. The list includes, for example, tests for the absence of adventitious agents, mycoplasma, and other microorganisms.

Testing is required for specific process-related and product-related impurities, depending on the vaccines being manufactured. In addition, tests are required for the bulking agent, stabilizing excipients, adjuvants, and/or preservatives, if used. All the testing should be done according to respective standard operating procedures (SOPs), and all tests should have specifications (or provisional specifications, where applicable).

Stability Test for Final Bulk

If final bulks are stored and/or subsequently shipped to a different location for further processing, the stability of these

materials should be demonstrated. Stability tests can be a combination of both physicochemical analysis and biological assays. Implementation of a stability program is required for formal stability studies, and the studies should be executed according to a protocol that contains detailed information about types of tests, including specifications, testing intervals, and data and analysis.

FINAL CONTAINER

A final container of vaccine contains the active ingredient(s) (i.e., antigen(s)) as well as additional components, such as stabilizers, adjuvants, or antimicrobial preservatives. They also may include residual materials from the manufacturing process.

Excipients and Other Additives

In addition to specific antigens, vaccines often include excipients and other additives that are intentionally added to the vaccine by the manufacturer for a specific purpose. These include adjuvants, antimicrobial preservatives, and stabilizers. Vaccines also contain manufacturing residuals, which are trace amounts of various components used during manufacturing. Thus, the combinations of these components comprise and define the complete vaccine product. Manufacturers must adhere to regulations governing permissible limits of such components, as indicated in the product's license.

Adjuvants—Adjuvants are agents incorporated into vaccine formulations to enhance and increase the immune responses generated by the vaccine antigens. Specifically, they can increase the amount of antibody produced, direct the immune response (Th1 or Th2), increase the duration of antibody presence (persistence), or produce a combination of these effects.

Aluminum compounds have long been the most widely used adjuvants worldwide. Two methods traditionally have been used for combining aluminum adjuvant to antigen to form aluminum-adsorbed vaccines. The first involves the addition of the antigen solution to preformed aluminum precipitate. The second involves the addition of an antigen to aluminum in solution and the addition of a compound that will coprecipitate the aluminum salt and the antigen *in situ*. Solutions of aluminum potassium sulfate, known as alum or aluminum chloride, have been used together with phosphate salts as precipitating agents. A number of aluminum adjuvant formulations are used in vaccines.

Tests for aluminum are based on metal detection tests described in the general test chapter *Aluminum* (206). Regulations limit the amount of aluminum permitted in a dose of vaccine. The Code of Federal Regulations [21 CFR 610.15(a), *Ingredients, preservatives, diluents, adjuvants*] states that "the amount of aluminum in the recommended individual dose of a biological product shall not exceed:

1. 0.85 milligrams if determined by assay;
2. 1.14 milligrams if determined by calculation on the basis of the amount of aluminum compound added; or
3. 1.25 milligrams determined by assay provided that the data demonstrating that the amount of aluminum used is safe and necessary to produce the intended effect and are submitted to and approved by the Director, CBER [Center for Biologics Evaluation and Research at FDA]."

The third criterion above aligns U.S. regulations with World Health Organization guidance for aluminum content in a single human dose of a vaccine product.

Note that adjuvants are not licensed by themselves; they do not constitute a product. Rather, a vaccine consisting of specific antigen(s) and an adjuvant are licensed together as a drug product.

Antimicrobial Preservatives—In the case of multiple-dose containers, antimicrobial preservatives are added to inhibit the growth of microorganisms that may be introduced from repeated puncture of multidose vials. With certain exceptions, a preservative is required to be present in vaccines marketed in multidose containers [21 CFR 610.15(a)]. Exceptions include yellow-fever vaccine; measles, mumps, and rubella (MMR); and dried vaccines when the accompanying diluent contains a preservative.

The microbial preservatives currently used in vaccines are thimerosal, 2-phenoxyethanol, benzethonium chloride, and phenol. These agents must pass the appropriate antimicrobial effectiveness test, as described in *Antimicrobial Effectiveness Testing* (51). Antimicrobial test challenges should be conducted as part of the normal formal stability program, including at expiration date. Various tests for preservatives can be found in *Antimicrobial Agents—Content* (341).

Stabilizers—The primary purpose of stabilizers is to protect certain vaccines from adverse conditions such as heat or to serve as a cryopreservative during the lyophilization process, usually the freezing step. The particular materials chosen for this purpose include sugars (e.g., sucrose or lactose), amino acids (e.g., glycine or glutamic acid [monosodium salt]), glycerol, and proteins (e.g., human serum albumin [HSA] or gelatin). Materials should be customized to a specific vaccine formulation and selected with patient safety in mind.

When a protein is chosen as a stabilizer, two main safety concerns arise. One stems from the source of the protein: animal or human origin raises the possibility of the presence of an adventitious agent. The second concern is the possibility of an allergic reaction in persons sensitized to that protein. This should be evaluated as part of the clinical program during vaccine development. At present two proteins are used as stabilizers for vaccines: HSA and gelatin. FDA requires that any serum-derived albumin used in manufacturing be U.S.-licensed HSA. FDA guidance further recommends that a statement indicating the source and related risks appear in the "Warnings" section of the labeling for HSA-containing products.

Gelatin or processed gelatin also is used as a vaccine stabilizer. The gelatin source may be either bovine or porcine. Although the conditions of manufacturing gelatin are harsh (i.e., the product is subjected to extremes of heat and pH), there remains a concern with bovine sources about the presence of the transmissible spongiform encephalopathy (TSE) agent, because this agent is known to resist such conditions. Therefore, if gelatin added to a vaccine or used in manufacturing is from a bovine source, the material should have the appropriate documentation certifying that it comes from a country or region that is in compliance with TSE guidance for industry.

Manufacturing Residuals—Vaccines may contain residual amounts of any of the materials used in the manufacturing process. These materials are termed manufacturing residuals. As a general principle, it is not possible to remove a particular substance completely, nor is it possible to conclusively demonstrate that a particular substance has been completely removed. Therefore the goal is to reduce these substances to an undetectable level, using a sensitive and validated analytical methodology. Some products are tested for pyrogenic substances as a manufacturing residual (see *Pyrogen Test* (151)); and, if the product is freeze-dried, it should be tested for residual moisture (see *Loss on Drying* (731)). Residual levels of manufacturing materials, including, if applicable, inactivating agents, should be justified. The release specifications of these components are required as part of the approved license.

Cell-Derived Residuals—Live attenuated bacterial vaccines are not usually subject to a high degree of postexpansion purification. But killed bacterial component vaccines typically undergo significant purification to reduce cell-derived residuals. Common cellular components to be reduced are proteins, nucleic acids, and polysaccharides. Assays for

these components are routinely conducted, if appropriate, to ensure purity. A common residual in bacterial vaccines made from Gram-negative bacteria is lipopolysaccharide (LPS), commonly known as endotoxin. Endotoxin testing is performed during the manufacturing process for any Gram-negative bacterial vaccine. In the case of Gram-positive bacterial vaccines, the endotoxin testing should be conducted to ensure that no contaminants from Gram-negative bacterial growth are present. Also, there must be a release specification for this residual. Two tests are currently used to detect LPS in biological products, the *Limulus* amoebocyte lysate (LAL) test (see *Bacterial Endotoxins Test* (85)) and the rabbit pyrogen test (see *Pyrogen Test* (151)). The *Limulus* lysate that is used to test for bacterial endotoxin in FDA-regulated products is itself a U.S.-licensed product. The rabbit pyrogenicity test requires the use of animals and is more difficult to perform; therefore, it is not employed to the extent that the LAL test is used.

Viral vaccine manufacturing requires cell substrates to produce the viruses, which are then taken through purification processes. Generally, killed viral vaccines are more highly purified than are live attenuated ones. Depending on the method used to manufacture the vaccine, manufacturers work with FDA to develop prudent specifications for the final vaccine. Animal-derived host cells have been used extensively in vaccine manufacturing, particularly viral vaccines. For example, influenza and yellow fever vaccines are produced, respectively, in egg allantoic fluid and chicken embryos. Mumps, measles, and some rabies vaccines are produced in chick embryo cells. The labels of these products must state that residual chicken proteins may be present in the final vaccine, and the label may indicate how much is present. Further, the label also urges practitioner caution when vaccinating a person with known hypersensitivity to eggs.

Two U.S.-licensed hepatitis B vaccines are based on recombinant DNA-derived proteins expressed in yeast cultures. In both cases, the labels notify health care professionals that yeast protein may be present in the vaccine and recommend that suitable precautions should be exercised. In the case of live viral vaccines, considerations may be given to the reduction of cellular residual materials (e.g., host DNA, proteins).

Materials of Animal Origin—Some raw materials and reagents, such as gelatin, calf serum (see *Bovine Serum* (1024)), or trypsin for vaccine manufacturing raise concerns regarding the potential presence of adventitious agents. Raw materials should be sourced from countries acceptable to FDA. Additionally, manufacturers should test these materials when possible to minimize the risks of contamination with adventitious agents. Reduction of serum components (e.g., BSA) should be considered in processing.

Antibiotic Residuals—Some antibiotics (but not penicillin) can be used in minimal amounts in the manufacturing process for viral vaccines, according to 21 CFR 610.15(c). Those that have been used include gentamicin, streptomycin, neomycin, and polymyxin B. There is no requirement for tests of residual levels of these antibiotics in the final vaccine. However, according to 21 CFR 610.61(m), the calculated amount expected to remain as a residual in the final vaccine, based on the amount added and the dilution factor in the manufacturing process, must be stated on the product label.

Inactivating Chemical Agents—Several chemical agents have been used to inactivate bacteria and viruses or to detoxify toxins in vaccine production processes. Formaldehyde and β -propiolactone are the most commonly used inactivating agents. Other less often used inactivating agents include glutaraldehyde and hydrogen peroxide. As a manufacturing residual, the inactivating agent should be removed from the final product as thoroughly as possible. The upper limit for formaldehyde is generally 0.02%, equivalent to 0.1 mg per 0.5-mL vaccine dose. The limit for β -propiolactone should be below the limit of detection.

EVALUATING THE STABILITY OF VACCINES

The stability of vaccine products depends on the nature of a vaccine antigen, the product formulation, and the control of vaccine storage prior to use.

Vaccine products are evaluated with programs that include real-time long-term storage under prescribed conditions. The use of extreme temperatures to potentially accelerate degradation may help manufacturers understand the stability of the product.

Vaccine products, like all pharmaceutical products, should be evaluated to define suitable conditions for storage (21 CFR 610.50 and 610.53). General principles of stability testing for biological products are described in *Quality of Biotechnological Products: Stability Testing of Biotechnological/Biological Products* (1049). Typically these concerns are focused on the final vaccine product, but evaluations also are needed for bulk intermediates to justify the conditions under which they are held. In both cases manufacturers define in advance the conditions to which the product will be exposed (e.g., temperature, light, and humidity) and the time range during which the product will be exposed to those conditions. Stability studies should evaluate all storage conditions to which the product or intermediate is likely to be exposed during production, handling, shipping, and storage so that appropriate time limits can be placed on the exposure to those conditions.

The primary criteria for defining the storage conditions for these intermediates and the final products are generally focused on acceptable maintenance of potency; but, as discussed below, there often are other attributes that need to be considered.

Evaluation of the stability of vaccine products has three general purposes. First, the products are shown to maintain an acceptable analytical profile throughout manufacture and use to preserve safety and effectiveness. Second, stability studies across several product batches provide an effective way to characterize the inherent properties of the product. This in turn leads to the third use, demonstrating manufacturing consistency in the product.

Stability Protocols

The overall experimental plan for evaluating the stability profile of a given set of product or intermediate batches typically includes specific definition of the conditions under which the samples will be stored and why these conditions are relevant, the length of time the samples will be stored at each condition, when samples will be tested during this time course, and the analytical measurements at each time point. Additionally, these stability protocols include itemization of the analytical procedures to be used. For stability studies that occur early in product development, the studies may be conducted to confirm the suitability of the product formulation and/or storage conditions. Later in development, stability studies are typically conducted to provide data supporting product dating period or intermediate hold time, to provide more elaborate product characterization, and to evaluate manufacturing consistency. These latter studies define product end-expiry specifications that allow definitions of acceptable and unacceptable product. Unacceptable product is defined as product that is no longer acceptable for use in clinical studies or for commercial use (e.g., because of degradation or loss of potency). Stability studies should be conducted over a duration sufficient to determine the point of loss of acceptable potency or other relevant parameters.

Analytical Measurements

Manufacturers should consider the rigor of the analytical method(s) used to evaluate the stability of complex products and improve their understanding of the parameters

that are critical to immunogenicity (including stability-indicator parameters). Selection of the stability-indicator parameters varies with each vaccine's unique characteristics.

The primary parameter that reflects stability for most vaccines is the potency assay (see *Potency Tests in Lot Release Testing*, below). This assay can take many forms, depending on individual vaccines (e.g., an infectivity assay for a live virus vaccine or a measure of the proportion of conjugated polysaccharide for a polysaccharide–protein conjugate vaccine). The potency assay is generally the key analytical result predicting whether a vaccine remains suitable for use and whether it will produce the expected clinical response. Other analytical measurements can provide important supplemental data, particularly those that have a clear link to the potency of the product. Examples include degradation profile, dissociation of a carrier protein from conjugated vaccines, and dissociation of an adjuvant from an antigen complex. Additionally, other common assays typically are performed as part of the stability study and may address physical or chemical changes in the product that may or may not affect its potency (e.g., general safety, degree of aggregation, pH, moisture, container, preservative, and enclosure).

Formal Evaluation of Stability Data and Product Expiry Dating

Vaccines must remain within potency specifications at the expiration date, provided that the product was stored under the normal conditions specified. Manufacturers should conduct stability studies to determine those storage conditions and that dating period to demonstrate that the product remains within the potency specifications. Manufacturers should conduct stability studies on a continuing basis. If a major manufacturing process changes, additional stability studies should be conducted to verify that there is no adverse impact on the stability profile. Under certain conditions such as process changes, accelerated stability studies could be conducted. An accelerated study involving temperatures both higher and lower than routine can evaluate the impact of temperature excursions on products. A similar evaluation should be done for product intermediates to establish how long a given intermediate can be held under defined conditions before it is processed further or discarded.

NOMENCLATURE

There are no uniform systems for naming new vaccines. 21 CFR 299 describes the cooperation of the FDA and the U.S. Adopted Names Council (USAN) in naming drugs, including vaccines. USAN is a private organization sponsored by the American Medical Association, USP, and the American Pharmacists Association. Section 262 in Title 42 of the Public Health Service Act requires that each package of the biological product be plainly marked with the proper name (name designated in the license 21 CFR 600.3) of the biological product contained in the package.

LABELING

Vaccine product labeling is regulated in compliance with 21 CFR 201 and 610. Requirements are set for container labeling and package labeling.

Container Label

Provisions are made for the following labels:

- Full label;
- Partial label; and
- No label on the container itself when the containers cannot support a label that includes all required information

and should be placed in a package that does include all required information.

The label should be affixed to the container in a manner that allows visual inspection of the contents for the full length or circumference of the container. If no package exists, the container bears all of the information required for the package label.

The full container label normally contains the following:

- Proper name of the product;
- Name, address, and license number of the manufacturer;
- Lot number or other lot identification;
- Expiration date;
- Recommended individual dose, for multiple-dose containers;
- The phrase *Rx only* for prescription biologicals; and
- Any applicable cautionary statements.

Package Label

In addition to the information required on the container label, the package label should describe the following:

- Any preservative used and its concentration, or the words *no preservative* if no preservative is used and its absence is a safety factor;
- Number of containers, if more than one; or
- Amount of product in the container, expressed as number of doses, volume, units of potency, weight, and equivalent volume (for dried product to be reconstituted); or
- A combination of the above to provide an accurate description of the contents, as applicable;
- Recommended storage temperature;
- The words *shake well*, *do not freeze*, or the equivalent, as well as other instructions when indicated by the character of the product;
- Recommended individual dose, for multiple-dose containers;
- Recommended route of administration, or reference to such directions in an enclosed circular;
- Presence of known sensitizing substances;
- Type of antibiotics added during manufacture and the amount calculated to remain in the final product;
- Inactive ingredients, when they constitute a safety factor or are referenced to an enclosed circular;
- Adjuvant, if present;
- Source of the product, when this may be a factor in safe administration;
- Identity of each microorganism used in manufacture and, if applicable, the production medium and the method of inactivation or reference to an enclosed circular;
- Minimum potency in terms of official standard of potency, or the words *no U.S. standard of potency*.

Prescribing Information

Detailed information about a vaccine appears in its prescribing information, commonly called the package insert. Increasingly, vaccines are distributed with patient package inserts written in lay language. Prescribing information (21 CFR 201.56 and 201.57) includes the following:

- Highlights of prescribing information
- Product names, other required information
- Boxed warning
- Recent major changes
 - a. Indications and usage
 - b. Dosage and administration
 - c. Dosage forms and strengths
 - d. Contraindications
 - e. Warnings and precautions
 - f. Adverse reactions
 - g. Drug interactions

- h. Use in specific populations (e.g., pregnancy, nursing mothers, pediatric, geriatric)
- i. Drug abuse and dependence
- j. Overdosage
- k. Description
- l. Clinical pharmacology
- m. Nonclinical toxicology
- n. Clinical studies
- o. References
- p. How supplied/storage and handling
- q. Patient counseling information

LOT RELEASE TESTING

General Principles

Manufacturers perform all appropriate tests for the licensed specifications for the product, according to 21 CFR 610.1 and 610.2. Samples of each licensed lot and protocols containing the manufacturers' test results are submitted to FDA. After FDA evaluates the protocol to ensure that the product specifications are met, and after satisfactory confirmatory testing, FDA approves the release of the lot if all tests meet the standards of safety, purity, and potency established for the particular vaccine product. After approval is granted, the manufacturer distributes and markets the product.

Guidelines are available regarding alternatives to lot release and a surveillance system. All of these variations are subject to the regulations in 21 CFR 610.2 that allow FDA to require that samples of any lot of licensed product (e.g., vaccine), together with the protocols showing results of applicable tests, be sent to FDA.

Common Tests

The tests common to all lots of all products include tests for potency, general safety, sterility, purity, identity, and constituent materials. The manufacturer completes these tests for conformity with standards applicable to each product. The results of all tests are considered, except when a test has been invalidated as a result of causes unrelated to the product (21 CFR 610.1).

Potency Tests (Vaccine-Specific)—The basic definition and requirements for vaccine potency and potency assays are provided in 21 CFR 600.3 and 610.10. A vaccine potency assay should indicate the therapeutic activity of the drug product as indicated by appropriate laboratory tests or by adequately developed and controlled clinical data. Potency may be expressed in terms of units by reference to a standard. Product potency tests vary with vaccine product types (e.g., viral, bacterial, live attenuated, inactivated, or polysaccharide). As a result, potency assays for vaccines span a variety of approaches to the expression of potency. In vitro potency tests for live virus may include plaque formation assays, endpoint dilution assays (e.g., the tissue culture infective dose [TCID₅₀], virus neutralization assays, or quantitative polymerase chain reaction [PCR] assays). Quantitative colony formation assays are used for live attenuated bacterial vaccines. Animal challenge tests for immunogenicity assays of potency, such as those for diphtheria and tetanus (U.S. Department of Health, Education, and Welfare, 1953; see *Appendix 2*), or rabies and anthrax show in vivo response. Antigenicity assays use enzyme-linked immunosorbent assays (ELISA), e.g., with hepatitis A or rate nephelometry and rocket immunoelectrophoresis (e.g., with pneumococcal polysaccharides). The potency tests for bacterial vaccines, such as the meningococcal polysaccharides, pneumococcal polysaccharides, or *Haemophilus b* protein conjugate vaccines use chemical and physical chemical assays. In the case of pure polysaccharide vaccines, the concentration or quantity of the vaccine component (polysac-

charide) and its quality (e.g., size) have been shown to be indicative of human immune response.

Assay precision and reproducibility vary with the different methodologies that are used in potency assays, ranging from the high accuracy and precision of chemical tests at one end of the spectrum to bioassays at the other end. The general test chapter *Design and Analysis of Biological Assays* (111) provides guidance for bioassays and applies to vaccine potency assays. Other tests should be validated as described in the general information chapter *Validation of Compendial Procedures* (1225).

Release Tests—Official release of vaccines by the vaccine regulatory authority may be based on either the bulk or the final container. It is highly desirable to perform potency tests on the final container. However, under certain circumstances this may not be practical or even possible; thus, a case-by-case approach would be required. The choice of whether to test the bulk or the final container derives from a number of considerations, such as the quantity of vaccine available for tests at the different manufacturing stages. For certain vaccines, both bulk and final container receive official release. The potency test is generally required for the final container. If it is not feasible to perform the potency test on the final drug product, the test is performed on the bulk material.

General Safety—For biological products that are intended for administration to humans, manufacturers perform a general safety test in order to detect any extraneous toxic contaminants. Procedures and exceptions are specified in 21 CFR 610.11.

Sterility—A sterility test of each lot of each product is conducted according to procedures described in *Sterility Tests* (71) and 21 CFR 610.12 for both bulk and final container material.

Bacterial Endotoxins—Each lot of final containers of a vaccine intended for use by injection is tested for bacterial endotoxins, as indicated in *Bacterial Endotoxins Test* (85).

Purity—Vaccines need to be free of extraneous material. Approved vaccine license applications indicate extraneous materials that are unavoidable in the manufacturing process for a specific product. The application may indicate test results and allowable limits for such materials, according to procedures described in 21 CFR 610.13.

Residual Moisture—Each lot of dried product is tested for residual moisture [see 21 CFR 610.13 (a), *Loss on Drying* (731), and FDA's *Guideline for the Determination of Residual Moisture in Dried Biological Products* (see *Appendix 2*)].

Pyrogens—Each lot of final containers of a vaccine intended for use by injection is tested for pyrogenic substances, as indicated in *Pyrogen Test* (151) and 21 CFR 610.13 (b).

Identity—The contents of a final container of each filling of each lot are tested for identity after labeling is completed. Identity is established by physical or chemical characteristics of the vaccine, inspection by macroscopic or microscopic methods, specific cultural tests, or in vivo or in vitro immunological tests. In large part, identity tests are performed to distinguish the subject vaccine from other materials manufactured at the same site (21 CFR 610.14).

Constituent Materials—Ingredients, preservatives, diluents, adjuvants, extraneous protein, cell culture-produced vaccines, and antibiotics are tested according to 21 CFR 610.15.

Permissible Combinations

Formulations that combine several vaccines must be licensed as combinations (21 CFR 610.17). The potency of each vaccine in the combination is individually tested and must meet the specifications in the context of the final combined product; other appropriate quality tests apply as well. For vaccines that are physically combined in clinical loca-

tions just before administration to a patient, prescribing information should describe specific procedures to follow in those settings.

Quality

In general, quality control systems for vaccine manufacture are identical to those routinely employed for production of other pharmaceuticals. These include raw material testing and release, manufacturing, process-control documentation, and aseptic processing. Manufacturers formally assign responsibility to designated staff for maintaining the continued safety, purity, and potency of the product and for ensuring compliance with applicable product and establishment standards, along with compliance with current GMPs. Analysts use reference standards and validated methods to determine active ingredients, residuals, and impurities. Manufacturers determine product safety in a variety of ways that may include the use of experimental animals, procedures to demonstrate product sterility, and tests to ensure product potency. The complexity of the quality control systems for vaccines lies in the variety of methods used to produce and control production. Lot release testing proceeds according to 21 CFR 610.2 and involves evaluating lots for safety, purity, and potency before release. Manufacturers follow FDA and applicable international standards for testing and validation. The basic considerations for validation are included in *Validation of Compendial Procedures* (1225), in addition to guidance documents issued by FDA and the International Conference on Harmonization (ICH) (see *Appendix 2*).

Alternative Tests

Modification of test methods or manufacturing processes as licensed may be permitted if the regulatory authority can be assured that the modifications cause no reduction in safety, purity, potency, and effectiveness of the biological product. It may be necessary for the manufacturer to file the proposed changes prior to implementation (21 CFR 601.12 and 21 CFR 610.9).

APPENDIX 1. TYPES OF VACCINES CURRENTLY LICENSED IN THE U.S. (EXAMPLES)

- Bacterial, live attenuated (e.g., *Salmonella typhi*)
- Bacterial, polysaccharide (e.g., meningococcal, pneumococcal)
- Bacterial, polysaccharide-protein conjugate (e.g., meningococcal, pneumococcal)
- Bacterial, toxoid (e.g., diphtheria, tetanus)
- Bacterial, extracts (e.g., pertussis, anthrax)
- Viral, live attenuated (e.g., influenza, measles, mumps, rubella)
- Viral, whole inactivated (e.g., rabies)
- Viral, subunit (e.g., influenza, hepatitis B, human papillomavirus)

GLOSSARY

1. **Acceptance criteria**—The product specifications and acceptance or rejection criteria, with an associated sampling plan, necessary for making a decision to accept or reject a lot or batch (or any other convenient subgroups of manufactured units).
2. **Active ingredient**—Any component intended to furnish pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment, or prevention of disease, or to affect the structure or any function of the body of man or other animals. The term includes those components that may undergo chemical change in the manufacture of the drug product and may be present in the drug product in a modified form intended to furnish the specified activity or effect.
3. **Adventitious agent**—A microorganism (e.g., bacteria, fungi, mycoplasma, spiroplasma, mycobacteria, rickettsia, viruses, protozoa, parasites, TSE agent) that is inadvertently introduced into the production of a biological product.
4. **Batch**—A specific quantity of a drug or other material intended to have uniform character and quality, within specified limits, and produced according to a single manufacturing order during the same cycle of manufacture.
5. **Biological product**—Any virus, therapeutic serum, toxin, antitoxin, or analogous product applicable to the prevention, treatment or cure of diseases or injuries of man.
6. **Cell bank**—Vials of cells of uniform composition (not necessarily clonal) derived from a single tissue or cell, aliquoted into appropriate storage containers, and stored under appropriate conditions.
7. **Cell line**—Cells that have been propagated in culture since establishment of a primary culture and have survived through crisis and senescence. Such surviving cells are immortal and will not senesce. Diploid

cell strains have been established from primary cultures and expanded into cell banks, but have not passed through crisis and are not immortal.

8. **Characterization**—Determination of the properties of a substance.
9. **Component**—Any ingredient intended for use in the manufacture of a drug product, including those that may not appear in such drug product.
10. **Container** (also final container)—The immediate unit, bottle, vial, ampule, tube, or other receptacle containing the product as distributed for sale, barter, or exchange.
11. **Control**—Having responsibility for maintaining the continued safety, purity, and potency of the product and for compliance with applicable product and establishment standards, and for compliance with current good manufacturing practices.
12. **Control cells**—Cells that are split off from the production culture and maintained in parallel under the same conditions and using the same reagents (e.g., culture medium) to perform quality control tests on cells that have not been exposed to the vaccine virus (which may interfere with some tests).
13. **Dating period**—The period beyond which the product cannot be expected beyond reasonable doubt to yield its specific results.
14. **Diploid**—Having the expected number of chromosomes for a species (i.e., two of each autosomal chromosome and two sex chromosomes).
15. **Drug product**—A finished dosage form (e.g., solution, suspension) that contains an active drug ingredient generally in association with inactive ingredients.
16. **End-of-production cells**—Cells harvested at the end of a production run or cells cultured from the master cell bank or working cell bank to a passage level or population doubling level comparable to or beyond the highest level reached in production.
17. **End-of-production passage level**—The maximal passage level achieved during manufacturing at final vaccine harvest. Cells may be evaluated at this level or beyond.
18. **Endogenous virus**—A virus whose genome is present in an integrated form in a cell substrate by heredity. Endogenous viral sequences may or may not encode for an intact or infectious virus.
19. **Expiration date**—The calendar month and year, and where applicable, the day and hour, that the dating period ends.
20. **Filling**—A group of final containers identical in all respects, which have been filled with the same product from the same bulk lot without any change that will affect the integrity of the filling assembly.
21. **Final bulk**—The stage of vaccine production directly prior to filling of individual vials.
22. **Free of and freedom from**—For a substance to be considered free of a contaminant, an assay must demonstrate that a defined quantity of the substance is negative for that contaminant to a defined level of sensitivity. The level of assay sensitivity is defined by the choice of assay and can be determined experimentally using standardized reagents. Alternatively, a validated process that is known to remove a contaminant to a defined level may be used to demonstrate freedom from that contaminant.
23. **Harvest**—Collection of material at the end of vaccine virus propagation in cell culture, from which vaccine will be prepared. This material may be the culture supernatant, the cells themselves (often in disrupted form), or some combination thereof.
24. **Inactive ingredient**—Any component other than an active ingredient.
25. **In-process material**—Any material fabricated, compounded, blended, or derived by chemical reaction that is produced for, and used in, the preparation of the drug product.
26. **Intermediates**—Unformulated active ingredients that are processed before final formulation and can be stored for long periods of time before further processing.
27. **Label**—Any written, printed, or graphic matter on the container or package or any such matter clearly visible through the immediate carton, receptacle, or wrapper.
28. **Latent virus**—A virus that is present in a cell, without evidence of active replication, but with the potential to reactivate, is considered to be microbiologically latent.
29. **Lot**—A batch, or a specific identified portion of a batch, having uniform character and quality within specified limits; or, in the case of a drug product produced by continuous process, it is a specific identified amount produced in a unit of time or quantity in a manner that assures its having uniform character and quality within specified limits.
30. **Lot number, control number, or batch number**—Any distinctive combination of letters, numbers, or symbols, or any combination of them, from which the complete history of the manufacture, processing, packing, holding, and distribution of a batch or lot of drug product or other material can be determined.
31. **Manufacture**—All steps in the propagation or manufacture and preparation of products. Includes, but is not limited to, filling, testing, labeling, packaging, quality control, and storage by the manufacturer.
32. **Manufacturer**—Any legal person or entity engaged in the manufacture of a product subject to license under the Public Health Service (PHS) Act. Manufacturer also includes any legal person or entity who is an applicant for a license where the applicant assumes responsibility for compliance with the applicable product and establishment standards.
33. **Master cell bank**—A bank of a cell substrate from which all subsequent cell banks used for vaccine production will be derived. The master cell bank represents a characterized collection of cells derived from a single tissue or cell.
34. **Master virus seed**—A viral seed of a selected vaccine virus from which all future vaccine production will be derived, either directly, or via working virus seeds.
35. **Oncogenicity**—The property of certain biological agents (e.g., viruses) or materials (e.g., nucleic acids) that are capable of immortalizing cells and endowing them with the capacity to form tumors. Oncogenicity is distinct from tumorigenicity.
36. **Package**—The immediate carton, receptacle, or wrapper, including all labeling matter therein and thereon, and the contents of the one or more enclosed containers. If no package is used, the container shall be deemed to be the package.
37. **Passage level**—The number of times, since establishment from a primary cell culture, a culture has been split or reseeded.
38. **Population doubling level**—The number of times, since establishment from a primary cell culture, a culture has doubled in number of cells.
39. **Potency**—The therapeutic activity of the drug product as indicated by appropriate laboratory tests or by adequately developed and controlled clinical data. Potency may be expressed in terms of units by reference to a standard.
40. **Primary cells**—Cells placed into culture immediately after an embryo, tissue, or organ is removed from an animal or human and homogenized, minced, or otherwise separated into a suspension of cells. Primary cells may be maintained in medium, but are not passaged (split).
41. **Process**—A manufacturing step that is performed on the product itself which may affect its safety, purity, or potency, in contrast to such manufacturing steps

which do not affect intrinsically the safety, purity, or potency of the product.

42. **Proper name**—The name, designated in the license, to be used on each package of the product.
43. **Purity**—Relative freedom from extraneous matter in the finished product, whether or not harmful to the recipient or deleterious to the product. Purity includes but is not limited to relative freedom from residual moisture or other volatile substances and pyrogenic substances.
44. **Qualification**—Determination of the suitability of a material for manufacturing based on its characterization.
45. **Safety**—The relative freedom from harmful effect to persons affected, directly or indirectly, by a product when prudently administered, taking into consideration the character of the product in relation to the condition of the recipient at the time.
46. **Specification**—The quality standard (i.e., tests, analytical procedures, acceptance criteria) provided in an approved application to confirm the quality of products, intermediates, raw materials, reagents, components, in-process materials, container-closure systems, and other materials used in the production of a product.
47. **Standards**—Specifications and procedures applicable to an establishment or to the manufacture or release of products, which are prescribed in this subchapter or established in the biologics license application and designed to ensure the continued safety, purity, and potency of such products.
48. **Sterility**—Freedom from viable contaminating microorganisms, as determined by tests prescribed by the FDA.
49. **Tumorigenic**—A property of certain cell types to form tumors when inoculated into animals (generally a syngeneic, an immunosuppressed allogeneic, or an immunosuppressed xenogeneic host). These tumors may be at the injection site or a different site and may also metastasize to other sites.
50. **Tumorigenicity**—The process by which immortalized cells form tumors when inoculated into animals. Tumorigenicity is distinct from oncogenicity.
51. **Unacceptable product**—Product that is no longer acceptable for use in clinical studies or for commercial use (e.g., because of degradation or loss of potency).
52. **Validation**—The performance characteristics of an analytical procedure, based on the demonstration that the procedure is suitable for its intended purpose or use. Validation of a process is the determination of the extent to which a process meets the requirements for the various performance characteristics and the demonstration that the process uniformly performs to defined characteristics. Validation is generally performed in accordance with *Validation of Compendial Procedures* <1225> and the relevant ICH guidelines.
53. **Viral clearance**—The combination of the physical removal of viral particles and the reduction of viral infectivity through inactivation.
54. **Virus seed or viral seed**—A live viral preparation of uniform composition (not necessarily clonal) derived from a single culture process, aliquoted into appropriate storage containers, and stored under appropriate conditions.
55. **Working cell bank**—A cell bank derived by propagation of cells from the master cell bank under defined conditions and used to initiate production cell cultures on a lot-by-lot basis.
56. **Working virus seed**—A viral seed derived by propagation of virus from the master virus seed under defined

conditions and used to initiate production cell cultures lot-by-lot.

<1237> VIROLOGY TEST METHODS

INTRODUCTION

This chapter describes virology test methods applicable to the development of biological product drugs, such as recombinant proteins, subunit vaccines, therapeutic monoclonal antibodies, and growth hormones. Several topics are excluded from the scope of this chapter:

- Blood- and plasma-derived products as well as whole blood and plasma products used directly in transplantation or infusion. However, the basic principles, strategies, and testing methods for ensuring virus-free products are applicable.
- Methodologies for the safety testing of live viral vaccines.
- Specific methods for viral clearance studies, which are described in the *USP* general information chapter *Viral Safety Evaluation of Biotechnology Products Derived from Cell Lines of Human or Animal Origin* (1050).

Virology test methods have historically been employed in the clinical settings of disease diagnosis, intervention, and containment; but the development of biological (biologics and biotechnology-derived) products and therapies for human or animal use has created the need for sensitive viral detection assays for use in the GMP production and testing of biological products. This need is not limited to the production of viral vaccines, but also applies to the development and manufacture of recombinant proteins, cell and gene therapies, and other products.

Sensitive virology test methods for quality control of biological products are necessary for several reasons. The production of biological products often requires a variety of raw materials and processing reagents of animal origin that have varying potential for introducing viral contaminants. The production of biological products may allow the replication of adventitious agents during processing, and therefore these materials must be prescreened to avoid the opportunity for contamination of the product. Another point to consider regarding screening these materials is that the product may not be compatible with processing methods used to eliminate or inactivate these adventitious agents. Because of the nature of the biological products, the production process needs to include appropriate testing regimens that monitor the possible introduction of adventitious agents and/or viral agents into the systems used. For these reasons, sensitive viral detection methods are required not only for the release testing of biological drug products, but also during the intermediate stages of processing, process development, and routine manufacture. Important stages for consideration include the development of cell substrates and banks, raw materials of animal origin, process intermediates, and critical excipients when derived from animal tissues. This strategy should be augmented with viral clearance and inactivation studies whenever possible.

For products intended to contain live viruses (e.g., infectious oncolytic viruses and live viral vector products used for gene therapy), the cell- and animal-based infectivity methods discussed in this chapter may be useful only following neutralization of the specific viral entity contained in the product for any product that is intended to contain live vi-

ruses (e.g., infectious oncolytic viruses and live viral vector products used for gene therapy). Alternatively, selection of appropriate indicator cell lines or animal models in which the specific viral entity is known not to replicate can be considered. It should also be expected that assay systems based on detection of viral particles or viral components will indicate the presence of the viral entity itself in such products, but may not indicate the viability of the virus. The remainder of the chapter is divided into three sections discussing assays for the three topics: (1) *Detection of Viable Viruses*, (2) *Detection of Viral Components*, and (3) *Detection of Antibodies to Viral Antigens*. The chapter covers the classic virology methods that are still routinely used, as well as modern molecular and immunological approaches. The methods described in these sections may possess different sensitivities to diverse viruses; they are therefore intended to complement each other to provide a science-based foundation for the detection of adventitious viruses. Multiple methods may be used in complementary fashion to improve the pathogen safety margin of a product. Identification of viruses detected in cell-based assays on the basis of cytopathic effects often depends on the use of molecular and immunological analyses; these analyses are therefore relevant both to viral detection and to subsequent viral identification. The chapter provides an overview of the detection and analysis of the most important groups of viruses as well as the most commonly used techniques. Tests specific to individual vaccines or biological products are excluded, because they are expected to be included in monographs for such products.

Methods that are well established with little variation in practice are described in more detail, whereas methods that are more flexible are described in general terms, both in the performance of the tests and in considerations for acceptance. Relevant regulatory references are given in the *Appendix*. Relevant USP general chapters should be consulted with regard to bioassay design, data analysis, interpretation, and assay validation.

DETECTION OF VIABLE VIRUSES

Infectious virus particles contaminating biologics and biotechnology-derived products are of great safety concern, because they have the potential for causing serious, possibly life-threatening, infections in the patients treated. This is particularly true if the patients are immunocompromised. Although complete assurance of viral safety for finished biological products can never be realized, a significant safety margin can be established through viral detection methods applied to unprocessed bulk and raw materials before purification in combination with purification processes that demonstrate the ability to inactivate or remove potential viral contaminants present at levels too low to detect. (See *Viral Safety Evaluation of Biotechnology Products Derived from Cell Lines of Human or Animal Origin* (1050) for information on viral clearance and inactivation methods.) For cell and gene therapy products that lack extensive purification steps, final products may be directly tested for the presence of relevant contaminating viruses. This section describes two broad systems for the detection of infectious virus: cell culture-based infectivity assays and *in vivo* infectivity assays. These systems may possess complementary sensitivities for viruses, and as a result, both methods may be used as limit tests for cell bank and raw material characterization and for lot release testing of biologics and biotechnology-derived products. Considerations for optimizing sample preparation for these tests are discussed, followed by a description of the more commonly employed detection assays. Finally, to ensure the reliability of experimental results, quality control issues in general and detection limit estimation in particular are discussed.

Sample Selection of and Preparation for Cell- and Animal-Based Virus Detection Assays

The requirements for selection, preparation, and storage of test samples for viral detection methods (cell- and animal-based) are dictated by the lability of the viruses being detected. The ability of a virus to remain infectious in the absence of a host cell is highly variable. Virus infectivity also may differ in sensitivity to repeated freezing and thawing cycles.

Sample preparation typically involves storage of test samples at low temperatures (ideally -60° or below) as soon as practicable upon collection. When intended for use in a viral screening assay, aliquots of samples should be prepared to avoid multiple freezing and thawing. Samples intended for viral infectivity assays are typically shipped with sufficient dry ice to last several days more than the expected time required for transit. When received at the testing laboratory, the sample should be examined to verify that it is still frozen, and appropriate documentation should be completed. For any storage or hold condition, the impact of the condition on viral viability should be empirically assessed and sufficient cold chain management ensured.

Typical sample types for viral detection assays are described below.

Cell Lysates—Test samples derived from cell substrates (master and working cell banks, end-of-production cell samples) are prepared in a manner that allows sampling of both the cells (for cell-associated viruses) and the conditioned medium (for virus shed into the medium). To achieve this, a culture of the cells is sampled. A cell suspension of $\sim 10^7$ cells per mL in conditioned medium is prepared and frozen (ideally at -60° or below). Because this medium does not contain cryopreservative, the majority of the cells will lyse upon thawing of the sample, releasing the cell-associated virus. Low-speed centrifugation will remove larger cellular debris and yield a supernatant that may be inoculated directly onto detector cells in cell-based viral infectivity assays. A similar sample is prepared for *in vivo* viral adventitious agent testing. In this case, however, the test sample is thawed and injected without clarification into the various animal systems via the various described routes.

Biotechnology Bulk Harvest (Unprocessed Bulk Harvest) Samples—Routine lot testing of bulk harvest samples is mandatory for most types of biologics (see *Viral Safety Evaluation of Biotechnology Products Derived from Cell Lines of Human or Animal Origin* (1050)). The sampling must be done at the unprocessed bulk harvest stage, because downstream purification processes may remove or inactivate any viruses that might contaminate the starting materials. The harvest sample from the bioreactor should be collected and stored without further manipulation, as soon as practicable, at -60° or below. To prevent multiple freeze and thaw cycles, individual aliquots should be prepared for each individual assay to be performed. Additional aliquots should be retained in case repeat testing is required. Depending on the nature of the manufacturing process, the bulk harvest samples may contain varying quantities of the production substrate cells. Because the bulk harvest does not contain cryopreservatives, the majority of the cells present will lyse upon thawing of the sample, releasing the cell-associated virus. Low-speed centrifugation to clarify the sample will result in a supernatant that may be inoculated directly onto detector cells in cell-based viral infectivity assays. There may be instances where the test sample is cytotoxic to the detector cells of the cell-based assays and procedural modifications may be required to deal with this. A similar sample is prepared for *in vivo* viral safety testing. In this case, however, the test sample is thawed and injected without clarification into the various animal systems via the various described routes.

Raw Materials of Animal Origin—Ingredients of animal origin used in the manufacture of biological products for human or veterinary use must be tested for species-specific viruses of concern as described in 9 CFR 113.53 (see also the USP general information chapter *Bovine Serum* (1024), being prepared for future publication). The raw materials may be stored under a variety of conditions, as appropriate to the raw material. Sample preparation and method of application to the test system depend on the nature of the sample. The possibility that animal-derived raw materials may contain bacterial or fungal contaminants should be considered. In some cases, it may be necessary to treat the samples with antibiotics or to filter the samples (0.22 or 0.45 micron pore size) prior to inoculation in order to prevent bacterial or fungal outgrowth in the test system. Animal sera are typically received frozen and are thawed and incorporated into the growth medium at an appropriate concentration (typically 15%, v/v) as a means of exposing the detector cells. Powdered trypsin (not less than 5 grams, as per 9 CFR 113.53) is suspended in a suitable diluent, such as phosphate-buffered saline, and is then subjected to high-speed centrifugation to pellet any virions that may be present. The concentrated pellet is resuspended in phosphate-buffered saline, and the resulting material is used to inoculate appropriate detector cells. Medium additives, such as bovine thrombin, may be incorporated into the growth medium at a predetermined multiple of the nominal concentration to be used in the manufacturing process. The resulting growth medium containing the additives is then used as a means of exposing the detector cells to the test material. The exact multiple to be used in such testing may be limited by such factors as solubility in growth medium or cytotoxicity to the detector cells. These factors should be assessed in advance of testing. The principle of using higher concentrations in the detection method than during processing should be followed, within the bounds of indicator cell toxicity, as a means to increase sensitivity to detection.

Whole Cells—Intact viable cells are used as the test sample in certain viral detection assays. Because the test cells may attach and proliferate in the culture vessel along with the detector cells, assays using this type of sample are referred to as cocultivation assays. The requirements for the specific assay may vary in relative proportions of detector and test cells, viability of the test cells, or the confluency of test cells at the time of collection.

Cell Culture-Based Viral Detection Methods

To ensure the absence of adventitious viral agents, cell culture-based viral detection assays are used for a variety of purposes, including but not limited to clinical diagnostic procedures; evaluation of raw materials and cell substrates; assessments of the viral identity, the purity, and the potency of virus seed stocks; and lot release testing of unprocessed bulk harvests during biologics production. An important distinction between cell-based assays and direct detection assays (see the section *Detection of Viral Components*) is that the former will detect only replicating virus, whereas the latter will detect viral antigens, viral genomic material, and the like, which may or may not be indicative of the presence of replicating virus. Similarly, detection of circulating antibodies directed against viral antigens (discussed in the section *Detection of Antibodies to Viral Antigens*), may be indicative of either a current or a past infection of an animal and does not necessarily indicate that the animal is currently harboring an infection.

Infectious viruses detected in cells or in cell-derived materials fall into two broad categories, based on the expectations of the analyst. Endogenous viruses are those normally detected in the cells as a result of the integration of the viral genomic material into the host cell DNA. Exogenous viruses

are those not normally present in the cells but found as a result of a viral infection of the cells.

The underlying assumption for all cell-based viral detection methods is the ability of viruses to replicate in an appropriate host cell. Viruses lack the cellular machinery required for producing their own genomic material and structural proteins, and they must therefore enter and subordinate a host cell for this purpose. Cell-based viral infectivity assays use indicator (detector) cells that serve as host cells for viable virions present in test samples.

Cell-based infectivity assays may be placed in three broad categories on the basis of types of viruses to be detected: (1) retroviral assays, (2) virus-specific assays, and (3) viral screening assays. The types of endpoints used to detect the viruses may differ by category. Although screening assays are typically not optimized for single viral entities, the virus-specific assays and titration assays, as well as some of the retroviral assays, may be optimized to some extent for specific viruses. Accurate titration of stock viruses that are used as positive controls or are used to determine the detection limit of an assay is critical.

The regulatory guidance underlying the various viral safety tests depends on the nature of the samples to be evaluated, and analysts are referred for more detail to documentation relevant to their own regulatory environments.

GENERAL REQUIREMENTS FOR CELL CULTURE-BASED ASSAYS

Detector Cells and the Concept of Viral Host Range—

The range of viruses detectable using a cell-based infectivity assay depends on a number of factors, including the type of host cell(s) used as the indicator (detector) cultures and the detection endpoints used in the assay. Viruses differ in their abilities to infect specific host cell types. Most viruses exhibit at least some degree of host cell tropism (i.e., ability to infect a specific species or tissue type). This attribute is typically due to a requirement for interaction of a virion with a specific cell membrane receptor during the process of infection of the host cell. A cell susceptible to infection and capable of production of progeny by a given virus is referred to as *permissive* for that virus; cells not supporting viral proliferation are referred to as *nonpermissive*, or *restricted*, for that virus. As a consequence of the differences in host cell tropism, assays intended to screen for a wide range of viruses must include multiple detector cell types. For the same reasons, design of a cell-based infectivity assay for a specific virus must include a detector cell known to be permissive for that virus.

Virus Susceptibility of Common Cell Lines—For most endpoint assays used to determine whether a host cell is infected with a virus, a monolayer culture is preferable to a semiaherent or suspension culture. For instance, cytopathic effect and hemadsorption are visualized microscopically. Cells that are not adherent have little morphology to evaluate, and hemadsorption cannot be properly evaluated in a suspension culture. For this reason, some regulatory documents pertaining to cell-based virus infectivity assays stipulate the use of monolayer detector cultures.

A list of commonly employed indicator cell lines and their application in viral screening assays is provided in *Table 1*. Regarding the viral tropism of these cells, "Points to Consider in the Characterization of Cell Lines Used to Produce Biologicals" (1993) and ICH's Q5A (R1) guidelines (for these references, see *Appendix*) require that human diploid cells such as MRC-5 and WI-38, which are permissive for a range of viruses of human concern, and monolayer cultures of the same species as that of the cell substrate used to produce the product are included in the viral screening test for biologics destined for use in humans.

Table 1. Indicator (Detector) Cell Lines Used for Adventitious Viral Screening Assays

Cell Line ^a	Origin	Endpoint(s) ^b	Target virus(es)
<i>Cell lines with relatively broad viral tropism:</i>			
BHK-21	Syrian hamster	CPE, HAd, HA	Insect-borne viruses (arboviruses)
Vero	African green monkey	CPE, HAd, HA	Viruses infectious to humans, primates
<i>For processes involving human cell substrates:</i>			
HeLa	Human	CPE, HAd, HA	Viruses infectious to humans
MRC-5	Human	CPE, HAd, HA	Viruses infectious to humans
<i>For processes involving Chinese hamster cell substrates:</i>			
CHO-K1	Chinese hamster	CPE, HAd, HA	Viruses infectious to Chinese hamsters
<i>For processes involving mouse cell substrates:</i>			
MEF	Mouse	CPE, HAd, HA	Viruses infectious to mouse cells
NIH/3T3	Mouse	CPE, HAd, HA	Viruses infectious to mouse cells
<i>For processes involving bovine cell substrates or bovine raw materials:^c</i>			
MDBK	Bovine	CPE, HAd, HA	Bovine viruses
BT	Bovine	CPE, HAd, HA	Bovine viruses
EBTr	Bovine	CPE, HAd, HA	Bovine viruses

^a Examples of cell lines used for viral screening assays are shown. MRC-5 and Vero, or cells with similar host ranges, are used in all assays. Depending on the cell substrate used to manufacture a biologic, additional cell lines are also used in the screening assay. In addition, a bovine cell might be included if bovine serum was used in the manufacturing process.

^b CPE, cytopathic effect; HAd, hemadsorption; HA, hemagglutination (optional).

^c Inclusion of a bovine cell in a virus screen should not be construed as a replacement for or alternative to a raw materials test. Raw materials testing is driven in the U.S. by 9 CFR 113.47 and 113.52, and cell lines used for this testing are described in Table 2.

A list of commonly employed indicator cell lines and their application in raw materials testing assays is provided in Table 2.

Table 2. Indicator (Detector) Cell Lines Used in Raw Material Testing

Cell Line ^a	Assay Type	Endpoint(s) ^b	Animal Origin of Raw Material
Vero	Isolation/detection	CPE, HAd, IFA	All sources
BT	Isolation/detection	CPE, HAd, IFA	Bovine; all sources (BVDV) ^c
EBTr	Isolation/detection	CPE, HAd, IFA	Bovine; all sources (BVDV) ^c
MDBK	Isolation/detection	CPE, HAd, IFA	Bovine; all sources (BVDV) ^c
PT-1	Isolation/detection	CPE, HAd, IFA	Porcine
PK-1	Isolation/detection	CPE, HAd, IFA	Porcine

^a The requirement (9 CFR 113.47 and 113.52) for evaluating raw materials of animal origin is to use (1) Vero cells, (2) a bovine cell for detecting BVDV, and (3) a cell line of the same species of origin as the raw material for detecting viruses of concern from that species. Examples are given of some cell lines that are used in the industry.

^b CPE, cytopathic effect; HAd, hemadsorption; IFA, immunofluorescent antibody staining.

^c As per 9 CFR 113.47, raw materials of any animal origin are to be tested for bovine viral diarrhea virus (BVDV).

Table 2. Indicator (Detector) Cell Lines Used in Raw Material Testing (Continued)

Cell Line ^a	Assay Type	Endpoint(s) ^b	Animal Origin of Raw Material
MDCK	Isolation/detection	CPE, HAd, IFA	Canine
GT	Isolation/detection	CPE, HAd, IFA	Caprine

^a The requirement (9 CFR 113.47 and 113.52) for evaluating raw materials of animal origin is to use (1) Vero cells, (2) a bovine cell for detecting BVDV, and (3) a cell line of the same species of origin as the raw material for detecting viruses of concern from that species. Examples are given of some cell lines that are used in the industry.

^b CPE, cytopathic effect; HAd, hemadsorption; IFA, immunofluorescent antibody staining.

^c As per 9 CFR 113.47, raw materials of any animal origin are to be tested for bovine viral diarrhea virus (BVDV).

There may be very specific requirements for detector cells for certain viruses. For instance, assays intended to detect infectious HIV use human peripheral blood lymphocytes and involve a p24 antigen capture enzyme immunoassay endpoint. A list of commonly employed indicator cell lines and their application in the detection of specific viruses is provided in Table 3.

Table 3. Indicator (Detector) Cell Lines Used for Detection of Specific Virus(es)

Cell Line ^a	Assay Type	Endpoint(s) ^b	Target Virus
324K	Isolation/detection	CPE, HAd, IFA	Murine minute virus
A9	Isolation/detection	CPE, HAd, IFA	Murine minute virus
BHK-21	Isolation/detection	CPE, HAd	Arboviruses ^c
MRC-5 ^d	Isolation/detection	CPE	Human cytomegalovirus

^a Examples of cell lines used for optimizing the detection of specific viruses or virus types are shown. In many cases, the assay methodologies must also be optimized for detection of the target viruses.

^b CPE, cytopathic effect; HAd, hemadsorption; IFA, immunofluorescent antibody staining.

^c Insect-borne viruses as a group are referred to as arboviruses. This term has no taxonomic significance.

^d Other human diploid cell lines such as WI-38 are also suitable. Assay duration must be 28 days at a minimum.

Growth Requirements for Detector Cells—Viral proliferation within a permissive host cell may be dependent on the rate of host cell proliferation. This is especially true for viruses that display cell-cycle dependence for generation of viral progeny. For most detection assays, detector cultures are seeded at a density intended to achieve a cell monolayer in exponential growth. This corresponds to a cell confluency of 50% or less (optimal cell densities may depend on the assay type and the detector cell to be used) at the time of inoculation of the cultures with virus or test sample. For the same reasons, the assay design may include provision for detector cell subculture (the collection of cells from the original culture and seeding of a predetermined fraction of these into a new flask). Alternatively, a passage may be performed, consisting of collection of conditioned medium from the original culture and inoculation of this material onto a secondary detector cell culture that is in log-phase growth. The frequency of subculture/passage required in an assay is determined largely by the rate of growth of the detector cell. Incorporation of these steps into detection assay designs helps to ensure that the conditions remain optimal for amplification of viral progeny within the host cells.

Need for Detector Cell Identification and Banking—

Detector cells used for cell-based viral detection assays are a critical reagent for ensuring viral safety, viral potency, viral identity, and viral clearance capacity in purification schemes. In many cases this testing is intended to support GMP processes; therefore, the detector cell banks may need to be prepared and qualified in much the same manner as other critical reagents. The details of the viral safety evaluation methods are described in *Viral Safety Evaluation of Biotechnology Products Derived from Cell Lines of Human or Animal Origin* (1050). Regardless of specific compliance requirements, periodic identification and qualification of the detector cell banks to be used subsequently for viral infectivity assays is good practice. The following should be regarded as minimal quality control testing for such detector cell banks: sterility, mycoplasma and viral screening, and cell identity by DNA fingerprinting, karyology, or isoenzyme analysis. In addition, specific assays for bovine and porcine viruses may be required if bovine or porcine raw materials were used in preparation of the banks. *Bovine Serum* (1024) and relevant serum-type specific ancillary materials monographs should be consulted when serum products are used in cell growth media.

Endpoints for Detection of Viral Infection

The various endpoints used to identify infection of a detector cell with a virus include the following:

- Visual observation of cytopathic effects
- Hemagglutination or hemadsorption of erythrocytes
- Immunofluorescent staining
- Cocultivation with other types of detector cells
- Quantitative polymerase chain reaction (qPCR) for direct detection of viral genomic sequences
- Electron microscopic analysis of viral pellets or fixed cells for visual observation of viral particles
- Biochemical endpoints such as reverse transcriptase assays, which detect virus-specific enzymatic activity

These various endpoints are used in a complementary fashion, because a given virus may not cause a positive response in each endpoint. For instance, some viruses can grow to high titers without producing visible cytopathic effects and so must be detected using other endpoints. Polymerase chain reaction (PCR) and electron microscopic analysis per se are not capable of distinguishing viable from nonviable viruses. However, when used in conjunction with cell culture growth kinetics, these approaches can be powerful orthogonal detection methods to demonstrate the increase of viral replication and therefore viable virus. The failure to observe viral particles in electron microscopic analysis of fixed cells should not be considered absolute proof of the absence of infectious virus in the cells. In a general sense, the same is true for each of the detection endpoints discussed above. Each endpoint has a detection limit below which a virus may be present but not detected.

Viral Cytopathic Effects—Visually observable manifestations of the infection of susceptible host cells with certain types of viruses are collectively referred to as viral cytopathic effects (CPE). Although CPE may be considered an indirect detection of viral infection, in the context of specific host cells they can have distinctive morphological manifestations. These may include the appearance of inclusion bodies, abnormal cell morphology, changes in culture confluency, cell death and cell lysis, and others. The nature of the CPE observed may depend on the host cell and the infecting virus. In addition, for a virus that normally causes CPE, there may exist variants that do not cause CPE. CPE can be differentiated from cytotoxic effect by the tendency of the former to exhibit progression irreversibly with time, whereas the latter may be reversible. In some cases structural proteins of viruses may cause cytotoxic effects similar to the cytopathic effects of the infectious virus. Differentiating the cytotoxic effect of such proteins from the cytopathic effect of infectious virus may require observation of the culture over time

to determine whether the effect progresses or the cells appear to recover. Alternatively, cell-free passage of the original culture onto fresh detector cells can be used to differentiate these two apparently similar manifestations. The cytotoxicity associated with the structural proteins in the absence of infectious virus would not be expected to pass to the secondary culture.

Giemsa staining may optimize the ability of the operators to visualize certain inclusion bodies (clusters of viral particles) that are characteristic of viral cytopathic effect and is required by 9 CFR 113.53 in assays used to demonstrate that bovine, porcine, equine, and ovine raw materials are free of species-specific viruses.

Detection of Hemagglutinating Viruses—A characteristic of certain viruses (referred to as hemagglutinating viruses) is that one or more of their viral proteins cause hemagglutination of one or more types of erythrocytes. Hemagglutination is an interaction between viral proteins or *hemagglutinins* and erythrocytes, leading to adhesion of the erythrocytes to surfaces, cells, and each other. This property forms the basis of two endpoint procedures that are employed in cell-based viral infectivity assays: *hemadsorption* and *hemagglutination*.

Hemadsorption is performed by adding a suspension of one or more erythrocyte types directly to the monolayer culture of detector cells. If viral proteins of a hemagglutinating virus are expressed from infected cell membranes, the susceptible erythrocytes will bind tightly to the cell membranes. Noninfected cells do not display this binding; therefore, the technique can be used to visualize a focus of infected cells against a background of uninfected cells. For this reason, this particular endpoint may display greater detection sensitivity than other assay endpoints, such as cytopathic effect or hemagglutination. In the advanced stages of infection, binding of erythrocytes to cells, to each other, and to open plastic surfaces in the culture vessel may be observed.

The hemagglutination procedure is performed on the conditioned medium and is essentially an evaluation for free virus or viral hemagglutinins in solution. An aliquot of the conditioned medium from a detector culture is combined, in a microwell plate having v-bottomed wells, with one or more types of erythrocytes. After an appropriate amount of time the plates are evaluated. Absence of hemagglutination is reflected by a well-defined pellet (button) of erythrocytes sedimenting to the bottom of the well. In comparison, hemagglutination is reflected by the absence of a button, or by a button with irregular shape. Scoring the latter represents an opportunity for operator subjectivity. In addition, this endpoint can be considered the least sensitive in detection assays, because it is dependent on achieving a sufficient concentration of viral hemagglutinins in solution. For these reasons, hemadsorption is typically viewed as the more useful and reliable of the techniques for detecting hemagglutinating viruses.

The responses obtained in detection assays using hemadsorption and hemagglutination endpoints are highly dependent on the virus being assayed, as well as on the types of erythrocytes used. Many of the viruses of concern to the biotechnology industry do not cause hemadsorption and hemagglutination, or their hemagglutinins react with red blood cell types not commonly used in detection assays.

Detection by Immunofluorescent Antibody (IFA)

Staining—Certain cell-based viral detection assays are intended to detect specific viral entities and are required for raw materials tests derived from bovine-, porcine-, equine-, and ovine-derived materials (9 CFR 113.53). In order to achieve this, the assays must be optimized with respect to host cell selection, study design, and sample preparation. Specificity of detection is also conferred through use of IFA staining techniques. Primary antisera or monoclonal antibodies directed against the viral antigens of interest are used, either in direct staining applications or in conjunction with a fluorochrome-conjugated secondary antiserum. The

immunostained detector cell monolayers are then visualized with an epifluorescence microscope to reveal the presence of reactive infected cells.

Design of Cell-Based Viral Assays

VIRAL DETECTION ASSAYS

Detector cell cultures are seeded and allowed to incubate for the appropriate amount of time. Viral samples may be inoculated directly into the medium of the mitotic phase of cell culture, but more typically the medium is removed from the overnight detector cell culture and is replaced with the test sample. For the latter method, the test sample must therefore be approximately isotonic, and cytotoxic agents such as selection agents must be maintained within levels tolerable to the detector cell. For test samples comprised of live cells, the sample must be subjected to freeze-thaw before inoculation in order to lyse the sample cells. If the cells are not lysed, a cocultivation involving the detector and sample cells will result. The latter is part of the design for cocultivation assays. But for most of the cell-based infectivity assays such a cocultivation is not intended and could adversely impact the sensitivity of the assay. The test sample is typically allowed to adsorb to the detector cell monolayers for an appropriate amount of time. It is then removed and replaced with the growth medium suitable for the detector cell. Once inoculated, the detection assay involves incubation of the detector cells for a prescribed amount of time, with periodic refeeding as necessary. Endpoint evaluations as described above are performed according to the study design. Variations of the given procedure may be used for exposing detector cells to raw materials. For raw materials, detector cell exposure may consist of incorporation of the test materials into the growth medium used to maintain the detector cells throughout the assay.

VIRAL TITRATION ASSAYS

Viral titration assays are designed to generate quantitative information about the virus of interest. These assays do not quantify absolute numbers of viral particles; rather, the results are expressed in terms of infectious units. An infectious unit is the amount of virus required to establish a productive infection, and several categories of titration assays are used. They vary on the basis of the endpoint used to demonstrate infection and include viral plaque titration or plaque-forming units (units: PFU per mL); 50% tissue culture infectious dose (units: TCID₅₀ per mL); and 50% fluorescent antibody infectious dose (units: FAID₅₀ per mL). The amount of a hemagglutinating virus in a sample can also be expressed in terms of hemagglutinating titer (units: endpoint dilution, i.e., the greatest dilution of the sample which still results in a positive hemagglutination, or HA, response).

Regardless of the endpoint used, a typical titration assay design consists of a sequence of sample dilutions based on 0.5 log₁₀ or 1 log₁₀ increments. The various dilutions of the sample are then applied to an appropriate number of replicate permissive detector cell monolayers. After a suitable incubation time, the monolayers are scored directly for cytopathic effect (TCID₅₀ assay), fixed and processed for immunostaining and scored for reactive cells (FAID₅₀ assay), or overlaid with agarose and processed for plaque generation PFU assay. TCID₅₀ and FAID₅₀ titers are typically calculated using published formulas, such as Spearman-Kärber and Reed-Muench. Assay controls for such quantitative assessments should routinely include a reference sample of known potency.

Detection of Retroviruses

Retroviruses represent a special case for cell-based viral detection assay because of the occurrence of retroviral infection in the absence of responses to the typical endpoints discussed. In order to detect retroviruses, scientists can employ a number of different endpoints. A list of commonly employed indicator cell lines and associated endpoints, and their application in retrovirus detection assays, is provided in Table 4.

Table 4. Indicator (Detector) Cell Lines Used in Retrovirus Infectivity Testing

Cell Line	Assay Type	Endpoint(s) ^a	Target Virus
SC-1/XC	Isolation/direct detection	Plaques (XC); RT	Ecotropic murine retrovirus
Balb/C	Isolation/direct detection	Plaques (XC); RT	B-Tropic murine retrovirus
NIH/3T3	Isolation/direct detection	Plaques (XC); RT	N-Tropic murine retrovirus
Mink Lung	Isolation	RT; mink S+L-	Xenotropic, amphotropic murine retrovirus
Mink S+L-	Direct detection	Foci	Xenotropic, amphotropic murine retrovirus
Feline S+L-	Direct detection	Foci	Xenotropic, amphotropic murine retrovirus, gibbon ape leukemia virus (GALV), and RD-114 feline retrovirus
<i>Mus dunni</i>	Isolation, cocultivation	RT; S+L-	Murine retroviruses and retroviruses infectious to humans
QT6 ^b	Isolation, cocultivation	RT	Avian retroviruses
RD	Isolation, cocultivation	RT; S+L-	Retroviruses infectious to humans
MRC-5	Isolation, cocultivation	RT; S+L-	Retroviruses infectious to humans
WI-38	Isolation, cocultivation	RT; S+L-	Retroviruses infectious to humans
293	Isolation, cocultivation	RT; S+L-	Retroviruses infectious to humans
A549	Isolation, cocultivation	RT; S+L-	Retroviruses infectious to humans

^a The endpoint assays include the following: RT, reverse transcriptase; PERT, product enhanced reverse transcriptase (including also product enhanced reverse transcriptase and real-time quantitative product enhanced reverse transcriptase assays); and EIA, enzyme immunoassay.

^b A quail cell; primary fibroblast cultures of chicken or turkey origin are also sometimes used.

Table 4. Indicator (Detector) Cell Lines Used in Retrovirus Infectivity Testing (Continued)

Cell Line	Assay Type	Endpoint(s) ^a	Target Virus
Raji	Isolation, cocultivation	RT	Retroviruses infectious to humans
Human PBMC	Isolation, cocultivation	RT, HIV p24 EIA	HIV and other human retroviruses

^a The endpoint assays include the following: RT, reverse transcriptase; PERT, product enhanced reverse transcriptase (including also product enhanced reverse transcriptase and real-time quantitative product enhanced reverse transcriptase assays); and EIA, enzyme immunoassay.

^b A quail cell; primary fibroblast cultures of chicken or turkey origin are also sometimes used.

Retroviral infection is dependent on the presence of receptors on the host cell membranes. The presence of such receptors confers host cell tropism.

DESIGN FOR RETROVIRUS INFECTIVITY ASSAYS

Two types of infectivity assays are used, depending on the nature of the test material. For materials other than intact cells, the test material is inoculated onto one or more of a variety of detector cells, and the latter are then passaged as required to amplify any virus present. Because of the nature of retroviral replication, cytopathic effects typically do not occur during infection, although there are some exceptions. Before the first subculture and at the end of the final passage, one or more endpoint assays are employed to detect the presence of a retrovirus. For test materials in the form of intact cells, detector cells are seeded and subsequently inoculated with the test cells, resulting in a cocultivation. The cultures are passaged five or more times. Before the first subculture and at the end of the final passage, one or more endpoint assays are employed to detect the presence of a retrovirus.

ENDPOINT ASSAYS FOR RETROVIRUS DETECTION

Endpoint assays may be classified as direct, which lead to distinct morphological changes in the detector cells; or indirect, as measured by the detection of biochemical, molecular, or immunological markers for infection.

XC-Plaque Assay—The XC-plaque assay was developed as a direct means of detecting infectious murine retroviruses. Detection of the retrovirus is accomplished by UV-irradiating the detector cells used to amplify the virus and overlaying the irradiated detector cells with a specific rat cell (XC). The presence of infectious murine retroviruses in the detector cells is reflected by the formation of distinctive syncytia in the XC monolayer, which are easily visualized when the cultures are fixed and stained with a suitable dye such as crystal violet.

The N/B tropism of an ecotropic murine virus may be determined by inoculating Balb/c and NIH Swiss detector cells with the isolate, performing one or two passages on each cell line, and comparing the XC-plaque titer post passage to that determined for the initial isolate.

Mink and Feline S+L[−] Focus Assays—The S+L[−] focus endpoint was developed to facilitate direct detection of infectious murine xenotropic and amphotropic viruses. The test sample may be inoculated directly into cultures of the S+L[−] cells, or, alternatively, may be amplified first by inoculation into mink lung, human, or *Mus dunni* detector cells. Cell-free supernatants from the detector cell cultures are used to inoculate the S+L[−] cells. The latter are infected with a sarcoma virus that is replication-defective, requiring the presence of a helper leukemia virus to render it capable of

causing transformation of the host cell. The presence of infectious retrovirus virus in the detector cultures is reflected by the formation of characteristic focal areas of cell transformation in the S+L[−] cells caused by the rescued sarcoma virus.

Detection of Retroviral Reverse Transcriptase—Assays designed to measure reverse transcriptase (RT) activity are useful as an indirect detection method, because the enzyme is indicative of the presence of all retroviruses, whether infectious or not. The RT enzyme is encoded for in the retroviral genome and is used by the virus to transcribe genetic information in viral genomic RNA into proviral DNA.

Radiolabeled Nucleotide Incorporation Assay—The earliest methods for measuring RT activity were based on the measurement of ³²P- or ³H-labeled nucleotide incorporation into the complementary cDNA product, using an appropriate RNA template. Incorporation of radiolabeled nucleotide at levels higher than a predetermined threshold is interpreted as evidence of the presence of retroviral RT activity. The contributions of cellular DNA polymerases can be ruled out through use of a dual template assay (having both RNA and DNA templates) or inclusion of activated calf thymus DNA.

Product-Enhanced Reverse Transcriptase (PERT) or Quantitative PERT (Q-PERT)—Polymerase chain reaction amplification has been used to increase the sensitivity of RT activity measurement. RT activity is detected by PCR amplification of complementary DNA, newly synthesized from an RNA template by reverse transcriptase. The assay may be performed with a gel endpoint (PERT) or as a quantitative assay (Q-PERT). This method has increasingly gained acceptance by regulatory agencies. For more details on PCR-based techniques, see the USP general information chapter *Nucleic Acid Based Techniques—Amplification* (1127).

Electron Microscopy—Transmission electron microscopy (TEM) may be used to detect and enumerate viral particles within cells. In addition, the technique allows for differentiation of types A, B, C, and D retroviruses based on morphological considerations and can be used to localize viral particles within the cell. As a technique for identification of viruses (including RNA and DNA viruses in general), TEM of sectioned cells is extremely valuable. The cells, typically sampled during the log phase of growth, are pelleted by low-speed centrifugation, and the cell pellet is fixed with a suitable fixative. The fixed cell pellet is embedded, sectioned, stained, and observed with TEM. Size (diameter) of the particles, morphology, presence or absence of surface features such as envelopes and spikes, and location within the cell can be determined with this technique. Such information is important for the identification of a virus. However, failure to observe viral particles with this method does not conclusively demonstrate the lack of viral contamination in the sample.

Biological fluids may also be evaluated by TEM, primarily to determine particle size and concentration. The cell-free supernatant is subjected to ultracentrifugation to pellet any virus present. The resulting pellet is fixed with a suitable fixative. A predetermined number of grid spaces containing representative areas of thin sections of the pellet are evaluated for particles. The enumeration results obtained may show a high degree of variability, and failure to observe particles does not imply that none were present in the sample. Molecular (quantitative PCR and quantitative PERT) endpoints have also been used as alternative methods for estimation of viral particle load in samples.

Antigen-Capture Enzyme Immunoassay—Specific viral proteins (e.g., HIV p24 antigen or avian leucosis viral envelope proteins) may be detected as a means of determining the presence of a retrovirus. Viral antigens are captured by specific antibodies coated onto microtiter plate wells and are detected by the addition of a second labeled antibody and appropriate substrate.

Assays Designed to Detect Specific Viruses

Additional methodologies have been developed to allow detection of specific viruses or groups of viruses. These types of assays are often used for raw material evaluation. In some cases, these specific assays were developed because the target viruses do not cause endpoint responses in the viral screening assays. In contrast to screening assays, specific virus assays are typically optimized for detection of the target virus or viruses. This optimization takes into account the lability of the virus, the host range, the possible endpoint responses elicited, and any special requirements of the target virus. The use of well-characterized viruses as positive controls in such assays provides assurance that the methodologies are suitable for the target virus or viruses. Spiking of the test sample matrix with the positive control virus enables the investigator to assess the potential for matrix interference and to assess the limit of detection for the method. Such considerations are not applicable to screening assays. Specific virus testing for bovine- and porcine-derived raw materials is discussed below. Evaluation of caprine, ovine, equine, canine, and feline raw materials is also stipulated in 9 CFR section 113.47. This section should be consulted with respect to the viruses of concern, and 9 CFR 113.52 should be consulted for methodology. A list of commonly employed indicator cell lines and their application in raw materials testing assays is provided in Table 2. A list of commonly employed indicator cell lines and their application in detection of specific viruses is also provided (see Table 3).

Detection of Bovine Virus Contamination—Raw materials of bovine origin include such commonly employed medium components as fetal bovine and calf serum, serum albumin, collagen, thrombin, and trypsin. Each of these additives represents a route of entry for adventitious viral contaminants into a cell culture or manufacturing process. Requirements for evaluation of such materials ensure the absence of contaminating viruses.

For the details on testing for bovine serum and its derivatives, see future general chapter *Bovine Serum* (1024).

Detection of Porcine Viral Contaminants—Raw materials of porcine origin include trypsin as well as other cell culture reagents. The specific porcine viruses of concern in the United States are stipulated in 9 CFR 113.47 and include porcine parvovirus, porcine adenovirus, transmissible gastroenteritis virus, and porcine hemagglutinating encephalitis virus. In addition, porcine raw materials must also be evaluated for the presence of bovine viral diarrhea virus (BVDV), reovirus, and rabies virus. Porcine tissues intended for xenotransplantation into humans also are routinely evaluated for the porcine endogenous retrovirus (PERV). The host cells typically used in the detection of porcine viruses are porcine testicle or porcine kidney, a bovine cell, and Vero cells. The methodology described in 9 CFR 113.52 is analogous to that for evaluation of bovine raw materials and includes provision for multiple subcultures, for Giemsa staining of fixed cells, for hemadsorption testing, and for use of specific immunostaining of fixed cells.

Cell-Based Detection of Murine Minute Virus—Murine minute virus (MMV) is a mouse parvovirus that has been detected in biologics manufacturing involving Chinese hamster cell substrates. As with other parvoviruses, MMV represents a special case in that the virus is difficult to inactivate using typical cleaning agents and is capable of surviving for prolonged periods of time on surfaces. Cell-based assays for MMV involve detector cell lines that are especially susceptible to this virus, such as 324K (a human cell) and A9 (a murine cell). Optimization for detection of a parvovirus also includes provision for detector cell subcultures to remain in log-phase division for a significant portion of the incubation period. Endpoints for detection of MMV include one or more of the following: cytopathic effect, hemagglutination of mouse and guinea pig erythrocytes, immunostaining, and polymerase chain reaction.

Cell-Based Detection of Insect-Borne Viruses—Insect-borne viruses include both viruses infectious only for insect cells (e.g., baculovirus) and those transmitted to mammalian cells via insect vectors (arboviruses). Detection of the former may be accomplished using an insect cell as a detector cell. Suitable substrates might include cells of *Spodoptera*, *Trichoplusia*, *Drosophila*, mosquito, or other insect origin. Such cells are typically cultured at lower temperatures (25° to 28°) relative to mammalian cells, and many of these cultures are suspension or semiadherent at best. Endpoints may include cytopathic effect, electron microscopy, and PCR.

Of more relevance to patient safety is the detection of arboviruses (insect-borne viruses infectious to animals and humans). This may be accomplished using a suitable mammalian detector cell. The Syrian hamster kidney cell (BHK-21) is a cell line that has shown susceptibility to a wide range of arboviruses. This cell line grows in a monolayer culture, and the endpoints that may be used include cytopathic effect, hemadsorption and hemagglutination, and PCR.

Cell-Based Detection of Human Cytomegalovirus—Human cytomegalovirus (CMV) is a slow-growing virus of special concern for biologics produced using human cell substrates. It may be detected in cell-based assays using human diploid detector cells such as WI-38 or MRC-5, provided that sufficiently long durations of incubation are employed (28 or more days). The endpoints include cytopathic effects and immunostaining and/or PCR.

IN VIVO METHODS

Intact and susceptible animals may serve as potential host organisms for detecting viruses in test samples. In this case, viral proliferation in the tissues of the host animal may be reflected as adverse health effects (including death) that can be monitored and recorded. Viral detection assays based on intact animals are intended to complement in vitro assays, because some viruses that do not cause a response in the in vitro assays may be detectable in the animal systems (and vice versa). Viral safety studies employing live animals must be performed in accordance with applicable regional guidelines for the ethical use of animals, using laboratories that are accredited for the housing of the animals.

In Vivo Viral Screen—The in vivo viral screen is used primarily for cell bank, viral seed stock, and viral vaccine testing and is considered to complement the in vitro virus screening assay. Multiple animal species, as well as multiple injection routes, are employed to provide a broad range of host tissues and possible responses. A list of commonly used host animals, routes of inoculation, and target viruses are shown in Table 5.

Table 5. In Vivo Viral Screening Assays

Host Animal	Route of Inoculation	Target Virus
Suckling mouse	Intraperitoneal injection	Arboviruses
	Intracranial injection	Coxsackie A and B
	Per os injection	Herpes simplex Type 1 and 2
		Togaviruses
		Junin
Adult mouse		Herpes B
	Intraperitoneal injection	Rhabdoviruses
	Intracranial injection	Togaviruses
	Per os injection	Lymphocytic choriomeningitis virus (LCMV)

Table 5. In Vivo Viral Screening Assays (Continued)

Host Animal	Route of Inoculation	Target Virus
Guinea pig	Intraperitoneal injection	Rhabdoviruses
	Intracranial injection	LCMV
		Lassa
		Junin
		Marburg
		Ebola
Embryonated hens' eggs		Vaccinia viruses
	Allantoic	Arboviruses
	Yolk sac	Equine encephalomyelitis viruses
	Chorio-allantoic membrane	Herpes viruses
		Influenza
		Mumps
		Newcastle disease
		Parainfluenza Types 1 and 2
		Rabies
		Vaccinia
		Variola
		Lymphogranuloma venereum
		Ornithosis

Following injection of the test sample, each animal model is monitored for an appropriate period of time that allows for the observation of clinical signs of viral infection. Any abnormality is investigated to determine the cause of the effect.

The suckling mice are observed for an appropriate period of time. Pooled homogenates from any surviving animals are then passaged into additional litters of suckling mice. The latter are observed for an additional period of time.

The guinea pigs are observed for clinical signs of viral infection and for injection site lesions. Necropsy for gross tubercular lesions is performed for certain types of test samples.

Allantoic fluids from eggs can be tested for hemagglutination of chicken, guinea pig, and human type-O erythrocytes. Additional fluids are pooled for each treatment group (test article and control), and these are passaged (inoculated) into a new group of embryonated eggs. Following an appropriate incubation period (typically measured in days), the allantoic fluids are again tested for hemagglutination of chicken, guinea pig, and human type-O erythrocytes. Following injection by the yolk sac route, the eggs are incubated for at least 9 days and are assessed for viability. The yolk sacs are then harvested and pooled for each group (test article and control), and a 10% solution of the resulting material is inoculated by the same route into a new group of embryonated eggs. The eggs are again incubated for an appropriate period of time (days) and are assessed for viability.

IN VIVO ASSAYS INTENDED TO DETECT SPECIFIC VIRUSES

Some in vivo assays are designed to detect, if not specific viruses, at least specific sets of viruses. The antibody production assays use the production of a humoral immune response in susceptible host animals inoculated with test samples. Viral antibody-free animals of the various species are injected with the test sample. At the end of an appropriate incubation period, one or more of a variety of endpoint assays may be performed to detect the generation of a humoral antibody response in the animal sera. Production in

the animal of antibodies directed against a specific virus provides evidence of the presence of viral antigen or infectious virus in the test sample. This type of assay is typically used to ensure that rodent cell banks and viral seed stocks are free of adventitious viruses. Three antibody production assays, along with the route of injection and target viruses, are summarized in Table 6.

Table 6. In Vivo Antibody Production Assays

Antibody Production Assay	Route of Injection	Target Virus
Mouse antibody production (MAP) assay	Intranasal	Ectromelia
	Intraperitoneal	Hantaan
	Intracranial	Mouse K
		Lactate dehydrogenase elevating virus
		Lymphocytic choriomeningitis virus (LCMV)*
		Murine minute virus
		Mouse adenovirus
		Mouse cytomegalovirus
		Mouse encephalomyelitis virus type II
		Mouse hepatitis virus
Mouse antibody production (MAP) assay		Epizootic diarrhea of infant mice
		Pneumonia virus of mice
		Polyomavirus
		Reovirus type 3
		Sendai
		Mouse thymic virus
		Lymphocytic choriomeningitis virus (LCMV)*
Hamster antibody production (HAP) assay	Intranasal	Polyomavirus
	Intraperitoneal	Reovirus Type 3
	Intracranial	Sendai
		Simian virus 5
Rat antibody production (RAP) assay	Intranasal	Hantaan
	Intraperitoneal	Kilham rat virus
	Intracranial	Mouse encephalomyelitis virus type II
		Polyomavirus
		Reovirus type 3
		Sendai
		Toolan's H1 virus
		Rat coronavirus/sialodacryoadenitis virus

* A group of test sample-injected mice is challenged with a known lethal dose of authentic LCMV. If this group of mice does not die from the challenge dose, a second group with twice the number of mice is used for a repeat challenge. If there are survivors in this group, the test sample is considered positive for LCMV.

Considerations for Validation, Matrix Qualification, and Quality Control of Cell- and Animal-Based Test Systems

Viral detection assays used to ensure the viral safety of human and animal therapeutics are expected to have undergone validation. The approach to the validation depends on the nature of the assay and associated regulatory compliance level.

Any assay should be sufficiently developed that it can be performed with an appropriate set of predetermined system

suitability and acceptance criteria. These criteria usually include the use of relevant negative and positive controls but may also include requirements for linearity and meeting of a predetermined detection limit. The results constituting a positive or negative response in the assay should be established prior to execution of the validation. An assay used under GMP compliance is expected to have been validated according to appropriate guidelines.

An assay used to ensure the safety of a commercially marketed biological product must be further characterized for suitability in the presence of the specific product matrix. The matrix qualification study should address the potential for specific interference with the viral detection endpoints used in the assay, and typically involves spiking of one or more model viruses into the product matrix at levels approaching the limit of detection to ensure the absence of interference.

For quantitative detection assays, the detection limit should be probed. This usually involves spiking of the model virus(es) at decreasing amounts into medium or the product matrix. The lowest spiking level of the virus reliably detected is used as an approximation of the actual limit of detection of the assay. Experimental error for these cell culture-based assays is usually expected to be in the range of 0.5 to 1 log₁₀. The determination of a detection limit is less meaningful for limit tests and viral screening assays in general. For the latter, knowledge of the detection limit for one virus does not imply a similar limit for another virus. Since screening assays are not optimized for a specific virus, the limit of detection for the assay can vary greatly from one virus to another.

Animal-based viral detection systems are generally not subject to the requirements for validation, matrix qualification, use of positive controls, and determination of detection limit that regulatory agencies expect of cell-based and biochemical tests. The use of animals for safety testing is subject to the regional guidelines for the ethical use of animals, and the kinds of activities listed above generally are not considered appropriate use of animals. However, negative control animals are included in these assays, and retrospective validation or gap analysis based on historic incidence of system suitability failures or positive findings is sometimes possible.

DETECTION OF VIRAL COMPONENTS

Direct detection of viral components can provide a direct measurement of viral levels in a sample preparation. It has also become primarily important for detection or identification of viruses in biological products or in the raw materials used in their manufacture. Systems capable of identifying components unique to specific phases associated with viral latency and replication are now available. During interaction with their host cells, viruses may incorporate modified host molecules during the production of new intact virus particles, or they may induce discernable changes in host cell makeup or function.

Most immunological methods and reagents currently available detect the constituents of intact virions. It is the relative abundance of these proteins that makes them most amenable to the development of antibody-based reagents. Abundance also makes them optimal targets for detection of the virus. Recently developed targeting and detection reagents are aimed at minor viral components that may be found only during specific phases of replication. These allow a more detailed analysis of the stage of viral infection. The basic methodology for the detection of viral antigens is well established, but more recent innovations in materials and reagent development have broadened its application.

Developments in the targeting and detection of viral nucleic acid components have led to enzyme-based systems for the amplification of nucleic acids in vitro and in situ (see *Nucleic Acid-Based Techniques—Amplification* (1127)). The potential specificity of this detection method allows the exami-

nation of biological systems with a high degree of confidence for the presence or absence of a specific targeted virus. A wide variety of reagents, technology platforms, and methodologies are available. The aim of this section is to elaborate on the most common practices and platforms used in the detection of viral components.

Sample Selection and Preparation for the Detection of Viral Components

This subsection addresses general considerations for various types of test samples and the most common assay targets (viral proteins and nucleic acids). The target proteins may have varying levels of posttranslational modification (e.g., glycosylation, phosphorylation), and the target nucleic acids may be either RNA or DNA, single or double stranded. Therefore, it is important to have a basic understanding of the physicochemical nature of the virus under study so that the sample handling procedures support the detection of the target component. For detailed considerations regarding the extraction of nucleic acids, see the USP general information chapter *Nucleic Acid-Based Techniques—Extraction, Detection, and Sequencing* (1126).

Types of Samples

Cellular—When viral components are associated with intact cells, samples must be generated either as whole cell lysates or as subcellular fractions. Maintaining the temperature of the test samples at or near freezing (0° to 4°) during processing and limiting the time that samples are held in an unfrozen state will reduce the potential for loss of target antigens and nucleic acids due to cytosolic enzymes (proteases, nucleases) present in the cell lysates. Reagents that can inactivate or limit the activity of such enzymes may be used to prevent degradation of the target components, especially when exceptionally labile samples must be handled at room temperature. Centrifugation of intact cells allows for some additional manipulation of the sample matrix. The growth medium can be discarded and the cells suspended in a buffer formulated to enhance the recovery and detection of the targeted viral component. Collection and storage parameters should also account for the presence of cellular DNA. This can increase the viscosity of the sample, rendering it difficult to pipet.

Tissue Culture Supernatant—Depending on the stage of the infection and the type of virus involved, the conditioned medium may represent a preferred test sample. An advantage is that the presence of cellular debris can usually be reduced through use of a low-speed centrifugation (clarification) step. The main disadvantage is the potentially low concentration of the analyte, and therefore concentration of the sample may be required.

Process Intermediate (Unprocessed Bulk Harvest)—In general, viral safety lot release testing is done at the bulk harvest stage prior to any purification. This is true regardless of whether the assay detects infectious virus or viral components. The presence of host cell DNA may need to be assessed in the case of biologics manufactured in animal cells.

Sample Stability and Matrix Effect

Sample stability is a key element in the successful detection of viral components. Protein structure can be altered by numerous environmental factors, including pH, ionic strength, solvents, detergents, temperature, and free radicals. In addition, complex biological matrices frequently contain proteolytic enzymes that can alter or destroy key antigenic features of a protein or peptide. Sample collection, storage, and handling must allow maintenance of the antigenic features targeted by reagent antibodies.

Conformational changes affecting the opportunity for antigen detection are difficult to address. Depending on the reagents required for detection, conformational changes may be required for antigen detection. For example, if antibodies are produced for an antigen detection system using native viral antigen, then unmasking and maintaining the conformation of the antigen throughout the sample preparation is essential. Conversely, if peptide fragments are used to produce antibody, then a denaturation step may be required to allow for effective antigen detection.

Conditions associated with sample preparation must be investigated in a combinatorial fashion whereby one parameter or component is varied while all others remain fixed. In this way, the formulation of lysis and processing buffers can be optimized for pH, ionic strength, and types of detergents and denaturants. The sample preparation steps must condition the targeted antigen in order to obtain the form most readily recognized by the reagent antibody.

The stability of nucleic acids in test samples is largely affected by nuclease activities present in the sample and the degree of protection provided by the intact structure of the virus particle. Encapsidated nucleic acids are particularly stable as long as the integrity of the capsid is maintained. Viral capsids are vulnerable to proteolytic digestion. Virus particles stored at ambient temperature as part of a complex biological matrix are especially susceptible to degradation by proteases. Storage at refrigerated temperatures (2° to 8°) for short periods of time or at temperatures below freezing can be used to limit proteolytic activity. When samples are stored at frozen temperatures, freeze-thaw cycles should be limited. Under conditions where an individual sample must be accessed multiple times, preparation of aliquots is advisable.

Sample Collection—In a biotechnology setting, sample collection is dictated by sampling plans that are established to meet regulatory requirements. Nucleic acid testing in association with an amplification step has the potential of detecting a virus at the earlier stages of infection. The use of nucleic acid amplification methods reduces the dependence on timing and the amount of material required, because the amplification process effectively boosts assay sensitivity by increasing the amount of target relative to background.

General aspects of nucleic acid sample preparation and stability are discussed in *Nucleic Acid-Based Techniques—Extraction, Detection, and Sequencing* (1126). The following section specifically addresses the unique aspects of viral sample selection and preparation.

Sample Storage—Conditions for sample storage should be consistent with maintaining the antigenic properties of targeted viral proteins and/or preserving the nucleic acid content of the sample. The duration and temperature of storage is dictated also by cycle times associated with testing.

Immune Complex Disruption—The masking of antigen epitopes may occur when other proteins associate at or near the epitope targeted by reagent antibodies. For viral antigens this may occur when the antigen comprises the structural component of the virus. Such viral antigens are likely to retain strong affinities for other viral proteins or the ability to exist in multimeric form under normal conditions for detection. Another obstacle for epitope recognition is the naturally occurring immune complex when reagent antibodies have been developed to detect native protein in a blood plasma matrix. Immune complexes consisting of viral antigens and host antibodies are normal in such physiologic samples. The stronger the host immune response, the more likely masking of antigen due to immune complex formation will occur. Methods aimed at the preparation of blood and plasma samples for detection should address the presence of preexisting immune complexes and incorporate steps designed to disrupt such complexes to improve the opportunity for viral antigen detection.

Detection of Viral Antigens

Viral capsid proteins are common targets for antigenic detection methods. Structural proteins that make up the framework of the viral core are often some of the most abundant viral proteins produced during viral replication. In nonenveloped viruses, the core structural proteins are likely to provide the dominant antigenic features. When the virus is enveloped, proteins associated with the envelope often provide key antigenic features. This section examines methods commonly used to detect viral antigens and addresses considerations aimed at optimizing formation of the appropriate immune complex.

ASSAYS USED FOR THE DETECTION OF VIRAL ANTIGENS

Immunologic methodologies used to detect viral antigens are based on the specificity and affinity of the antibody and viral antigen interaction. Of the various platforms available, one commonly employed in viral safety testing is immunofluorescent antibody staining. This lends some degree of viral specificity to the cell-based methods described in the first part of this chapter. Other techniques include enzyme-linked immunosorbent assay (ELISA), radioimmunoassay, and Western blotting. The principles and general methods for these assays will be described in the USP general information chapters *Immunological Test Methods—General Considerations* (1102), *Immunological Test Methods—Reagent Development* (1103), *Immunological Test Methods—Immunoassay Methodologies* (1104), and *Immunological Test Methods—Assay Design, Quality Control, and Data Analysis* (1105), being prepared for future publication. The following sections will generally address aspects specific to their use in virology.

Immunofluorescence Assay—The immunofluorescence assay (also referred to as immunofluorescent antibody staining) is used to detect viral proteins expressed in various cellular compartments. Since the technique can detect viral antigens within single cells, it confers a high degree of sensitivity and enables infection to be detected at a very early stage. The technique is often employed as a detection endpoint for cell-based viral infectivity assays to provide additional sensitivity and specificity (see tests for raw materials as described in 9 CFR 113.53). In addition, the technique is employed for verifying the identity of viral stocks and is useful as a means of identifying viruses detected in viral screening assays.

Enzyme-Linked Immunosorbent Assay (ELISA)—ELISA is best suited for detection of soluble antibodies and antigens in a variety of test samples. Sensitivity, quantification, robustness, ease of experimentation, and readily available inexpensive reagents make it adaptable to a high throughput environment. For viral antigen detection, a sandwich ELISA assay is commonly used. A viral antigen specific antibody (preferably a monoclonal antibody with high affinity) is first immobilized onto a solid phase. The test sample is then incubated for a predetermined period under appropriate conditions. After washing, a second antibody that recognizes the viral antigen is incubated. The second antibody is linked to either an enzyme or a chromogenic reagent that emits signal with an appropriate substrate and can be recorded with an appropriate instrument. The assay can be performed in a qualitative or a quantitative manner. For a qualitative ELISA assay, sufficient replicates of both positive and negative control samples are required in order to determine the appropriate cut-off value and the assay acceptance criteria. A mean value of a test sample that is equal to or greater than the cut-off value is considered positive. For a quantitative ELISA assay, an additional standard curve with a positive reference standard material of known quantity must be established. The number of replicates should be adequate to determine the assay variation and linearity. The

quantity of test sample can be calculated against the standard curve.

Radioimmunoassay (RIA)—The radioimmunoassay is a versatile quantitative immunoassay that can be used to detect substances including viral antigens and antibodies. It even can be applied to nonprotein molecules as long as an antibody that specifically binds the test substance is available. Radioimmunoassays can be customized in different formats to suit specific test requirements. Many of the considerations taken into account with other immunological assays are applicable to the RIA. In general, radioimmunoassays can be divided into two major categories: solution (homologous) and solid-phase radioimmunoassays. Both methods have been successfully used to detect and quantify a variety of viral antigens or components of viruses, such as hepatitis A, B, and C; human and murine retroviruses; adenovirus; avian C-type virus; rubella virus; and respiratory syncytial virus.

Western Blotting (Immunoblotting)—Western blotting, also known as immunoblotting, is used to identify specific antigens in the presence of other, potentially cross-reactive antigens. In this case, the specificity required is obtained by combining the antigen-antibody reaction with some form of separation (typically electrophoresis). Depending on the visualization methods employed (including digital methods such as densitometry), this method can be quite sensitive and even semiquantitative. One advantage of this approach is that in addition to detecting the antigen using an immunological approach, data on the approximate mass of the target protein may be obtained. A potential caveat is that most test proteins are denatured during this procedure and that antibody that depends on epitope conformation may not recognize the linear epitopes.

DETECTION OF VIRAL NUCLEIC ACIDS

The detection of viral nucleic acids provides another route for the determination of viral loads and for establishing the identity of a contaminant. Nucleic acids, like protein antigens, are essential components of viruses, and detectable quantities are usually indicative of viral presence. Detection assays can be designed and developed in some cases to parse viremia into phases, especially when the differentiation of nucleic acids along functional forms and configurations can provide clear insight into viral activity. Assays can be designed to determine whether viral DNA has been integrated into the host genome or still is encapsidated. Early viremia may be detected as viral mRNA transcripts prior to the accumulation of detectable viral particles. Nucleic acids may be the only detectable viral component of viruses that do not replicate well in tissue culture systems. Such systems may fail to produce mature virus particles, but the detection of viral transcripts can provide insight into whether the virus has the ability to infect the cell. Nucleic acid testing represents the most useful endpoint for the detection of certain viruses failing to cause responses using typical endpoints.

SAMPLE PREPARATION: SPECIAL CONSIDERATIONS FOR NUCLEIC ACID TESTING

The degradation of nucleic acids in samples can be limited through proper handling and storage practices and even enhanced by closely linking sample collection and preparation steps. In addition to preparing nucleic acids for further processing, denaturation is an important step toward stabilizing nucleic acids where storage temperatures extend above 0°.

Denaturation and Dissociation of Virions (Viral Lysis)—Chaotropic detergents and salts can be important agents for disrupting and removing viral proteins that make up the viral capsid. Their addition can provide a useful first step when concentration of virions is not necessary or even

possible. In sufficient quantity they rapidly denature the entire contents of a biological sample, essentially fixing nucleic acid content through the inactivation of nucleases and other proteins that may affect sample stability. Saturated solutions containing guanidium salts, such as guanidine hydrochloride or guanidine isothiocyanate, are commonly used for the dissociation of viral nucleic acids from protein components. These solutions may be used alone or in combination with ionic detergents and other denaturants such as phenol. The main advantage of guanidinium salts is that they are readily removed during the concentration of viral nucleic acids using ethanol or isopropanol. Urea may also be used as a mild denaturing agent, although it does not perform as effectively as guanidine in its ability to disrupt virus particles.

Deproteinization—The removal of proteins during the processing of samples for the detection of viral nucleic acids is helpful in ensuring the reproducibility and robustness of assays, particularly those that rely on amplification to detect exceptionally low quantities of nucleic acids. Several strategies may be used to facilitate deproteinization of the sample; they are discussed in *Nucleic Acid-Based Techniques—Extraction, Detection, and Sequencing* (1126).

Recovery of Viral Nucleic Acids—Separation and recovery of extracted viral nucleic acid are important steps in the testing of nucleic acids. Nucleic acid yield and purity obtained at this step are critical determinants of assay robustness. Poor nucleic acid recovery and limited purification may inhibit amplification and detection reaction resulting in poor assay sensitivity. The development of high-yield, high-purity recovery steps is an important goal in the optimization of nucleic acid detection methods. Details on the general aspects of extraction and detection of nucleic acids are discussed in *Nucleic Acid-Based Techniques—Extraction, Detection, and Sequencing* (1126). However, if no inhibitory components are identified in the system, direct testing on an aliquot of a sample may increase the assay sensitivity.

Isolation of Viral DNA—Integrated viral genomes must be recovered and processed along with the genome of the host cell. The viral genome is analyzed within the context of the host genome, and therefore similarities between virus and host genomes must be accounted for to ensure that assay results are specific for the virus and do not simply reflect the presence of cross-reacting host genome sequences. Viral genomes that exist as episomal entities require similar consideration, but there may be opportunities during sample preparation to limit the amount of host nucleic acid present in the preparation. Sedimentation gradients or silica-based separation chromatography can sometimes be used to enrich episomal nucleic acids through size-related exclusion or partitioning of processed nucleic acids.

The recovery of encapsidated viral genomes may allow for larger amounts of material, especially if the target virus has accumulated in large quantities in the system being monitored. When the amount of material available for recovery is low or the processing of large amounts of the material is impractical, the process of isolating and conditioning the virus particles, and subsequently the encapsidated genome, must be compatible with the assay system that will be used. Portions of the viral genome may need to be amplified, or the genome itself may be captured in an elaborate process that allows detection through the generation of an amplified signal. A standard method for isolating viral genomes may need to be modified appropriately to ensure that materials used in the preparation do not interfere with steps conducted later in the process.

Viral genomes that consist of RNA are typically converted to a DNA intermediate that is easier to handle and store. Methods aimed at the isolation of viral genomes consisting of RNA, however, require similar considerations concerning the localization of the genome: replicating RNA viral genomes may be recovered as part of a preparation of host total RNA or even mRNA if the genome contains polyA sequences. RNA lends itself more effectively to hybrid capture methods during isolation, and hybrid capture can be used

to enrich RNA preparations specifically for RNA viral genomes. RNA genomes can be extracted from virus particles in much the way that DNA viral genomes are extracted. RNA genomes are converted to complementary (cDNA) sequences using retroviral RT. Storage is of greater concern for naked viral RNAs. Storage of RNA usually requires temperatures below -20° .

DETECTION OF VIRAL GENOME VERSUS VIRAL TRANSCRIPTS

Viral genomes exist as either DNA or RNA, or sometimes both: in the case of retroviruses the integrated genome is DNA, whereas the encapsidated form is RNA. The ability to differentiate among the various forms of viral nucleic acids can help to elucidate the course of specific viral infections. Assays for nucleic acid activity can differentiate readily between integrated and encapsidated genomes when the form of the viral nucleic acid varies between states, as in the case of retroviruses. Incorporation of specific nucleases into the assay methodology can be used to reduce or eliminate one form over the other. If viral genomes are known to integrate at specific sites within the host genome, primers and probes can be developed around the integration site and incorporate significant elements of both host and viral genomes. Some viral mRNAs contain splice sites, and the differentiation of spliced nucleic acid sequences from unspliced sequences creates a unique mechanism for determining the status of nucleic acid localization and infection.

Characterization of DNA Viral Genomes—Methods for the recovery and preparation of viral genomes for characterization depend on the state of the viral genome. If the genome has been incorporated into a cellular compartment, the recovery and preparation strategy must take into account the cellular components that make up the sample matrix. If the viral genome targeted for analysis is the encapsidated form, the methods must focus on recovery of the virus particle and must include additional steps aimed at extracting the nucleic acid from the individual particles. Identification and characterization of viral genomes require specific complementary nucleic acid probes and primers whose sequence will be dictated by available information about the sequence of the targeted viral nucleic acids and the type of assay that will be used. Determination of the sequence of the viral nucleic acid of interest usually provides the most unambiguous means for characterization. However, a number of methods can be used as simple indicators for the presence or absence of specific sequence-based characteristics. For example, melting curve profiles using short oligonucleotide sequences can be used to establish whether a specific viral genotype is present.

Identification and Genotype Analysis—Nucleic acid testing is often used to identify viral isolates obtained from viral screening assays or to provide identity for viral stocks. Methods used for the identification of viral genomes are not unique to other applications in the field of molecular biology. Typically, an amplification step is required in order to achieve quantities for analysis. Amplified sequencing of the amplicons or application of a standard hybridization technique may be employed for more detail as to the nature of the amplified signal. For more details, refer to *Nucleic Acid-Based Techniques—Amplification* <1127>.

Hybridization Techniques—A variety of hybridization techniques are used to detect viral nucleic acid sequences, including Southern blot, Northern blot, DNase/RNase protection, in situ hybridization, microarray technology, and other techniques. The description of these methods, which is well beyond the scope of this chapter, can be found in *Nucleic Acid-Based Techniques—Extraction, Detection, and Sequencing* <1126>.

DETECTION OF ANTIBODIES TO VIRAL ANTIGENS

A variety of methods are available for detection and quantification of antibodies to viral agents, including neutralization, complement fixation, and immunoassays based on enzyme- or fluorescently labeled reagents. Although many details of the immunological methods mentioned above are beyond the scope of the chapter, this section addresses specific application aspects of viral antibody detection, including preparation and storage of test samples, common assay methods and platforms available, and specific examples of how these assays may be used to measure antibodies to specific viral agents.

Viral Structure Relative to Antigenic Composition and Selection of Antibody Assay

Mammalian viruses vary considerably in their nucleic acid content and thus the number of antigenic, virus-specific proteins produced.

Many viral proteins or glycoproteins are highly antigenic and induce a potent humoral immune response during natural infection, whether in humans or in animal models. In most cases, the immune system responds when the virus and its antigens appear in the extracellular fluid or on the infected cell membranes. The degree to which viral antigens are expressed is governed by the intracellular replication and protein synthesis of viruses in host organ tissues and by the several possible types of virus–host cell interaction. Antibodies produced as a result of natural viral infection are likely to represent the broadest response to antigens in their native state.

When selecting, developing, or evaluating an assay method for measurement of antibodies to viral proteins, the analyst must take into account the source of the antibodies and the method by which they were obtained or prepared. Details will be presented in *Immunological Test Methods—Reagent Development* <1103> and *Immunological Test Methods—Immunoassay Methodologies* <1104>.

General Considerations Regarding Sample Preparation for Antibody Detection of Viral Antigens

Antibodies are relatively stable, but care must be taken to ensure the integrity of the test antibodies during sample preparation and storage. Serologic tests may be developed to measure antibodies to viral agents in unfractionated biological fluids. The possibility for matrix interference with the antibody detection method should be considered.

In general, biological test samples should be clarified by centrifugation or filtration, depending on their intended use. Serum samples should not be hemolyzed, lipemic, or icteric. In some cases the specimen should also be heat-treated to inactivate endogenous complement and other components.

Test samples should be processed as soon as possible. When it is necessary to store samples, most test samples should be stored at -20° for short-term storage and below -80° for long-term storage. For all samples, the stability of the material needs to be assessed experimentally. Aliquots of appropriate volume should be prepared in accordance with test procedures to avoid unnecessary freeze-thaw cycles.

Antibody Methods

This section discusses the primary methods for detecting antibodies directed against viral antigens. The assay methods often include a variety of alternative formats for the detection of antibody. Only the more commonly used formats for antibody detection are discussed in this section. Some methods, including fluorescent antibody assays and

enzyme immunoassays, are widely applicable to the detection of antibodies to many different viral agents; others are limited to selected viruses having certain properties (e.g., hemagglutinins).

IMMUNOFLUORESCENCE MICROSCOPY FOR ANTIBODY DETECTION

When fluorescein isothiocyanate (FITC) is chemically coupled to an antibody molecule, the resulting *FITC-labeled antibody* can be used as a secondary antibody probe to detect the presence of a primary, virus-specific antibody bound to a virus-infected cell on a microscope slide (indirect immunofluorescence).

The indirect immunofluorescence or indirect fluorescent antibody (IFA) assay is one of the most basic and useful methods for detection of antibodies to viruses. The assay can be used to detect both virus-specific IgG- and IgM-class antibodies. When the assay is used to detect IgM antibodies, it usually requires the physical removal or inactivation/binding of IgG-class antibodies. In the absence of this step, the presence of IgM-specific antibody may be masked by excess IgG-specific antibody competing for primary binding sites on the substrate surface. IFA assays may be qualitative or quantitative.

The IFA for antibody to viral agents requires the use of virus-infected cells expressing viral antigens in cellular membranes. Viral stocks are prepared, titered, and used to infect permissive cells in tissue culture. The cells are harvested at appropriate times, washed, and spotted onto multiwell microscope slides at an appropriate density. Control slides are also prepared with noninfected cells. The slides are allowed to air-dry and then fixed in cold acetone. The fixed slides can then be stored under appropriate conditions for extended time periods. The stability of the viral antigens over time should be confirmed.

The test article to be examined for the presence of virus-specific antibodies can be applied to the slide, followed by an appropriate secondary antibody conjugated with a fluorescent tag that can be visualized under a fluorescent microscope. IgG- or IgM-specific antibodies can be distinguished by using the appropriately prepared secondary antibody.

Reading and correctly interpreting endpoints of IFA slides for antibody detection requires an experienced analyst, particularly when cellular location and fluorescent-staining patterns are critical for a specific virus. Such interpretation requires the use of appropriate controls and scoring or intensity of fluorescence. This is highly dependent on the quality of reagents, the consistency of the fluorescent microscopy and light source being used, and the experience of the analyst.

ENZYME IMMUNOASSAY FOR ANTIBODY DETECTION

The EIA and variations of it are the most widely used methods for the detection of viral antibodies in serum and other biological products. The most commonly used EIA for antibody detection is referred to as a noncompetitive solid phase EIA for antibody detection. The typical configuration of an EIA for antibody involves coating tubes or microwell plates with viral antigen(s), the addition of test serum or product to the tubes or wells, the binding of specific antibody in serum or product to antigen, and the detection of bound antibody by addition of a second antibody with binding affinity to the primary antibody, which is labeled to allow for its detection.

The assays can be specific to IgG- or IgM- class antibody or may detect total antibody. Assays for IgM may achieve improved specificity when performed as *IgM-capture* assays. These assays involve the use of plates or wells coated with anti-IgM antibody to capture total IgM in serum or product as a first step. Subsequently, viral antigen is added; it binds to the plate only if virus-specific IgM antibody has initially

been captured, and it is detected by addition of a second labeled antibody specific to viral antigen. The assay is most often performed as a qualitative measure of the presence of an antibody for a specific virus. Sufficient replicates of both positive and negative control samples are required in order to determine the appropriate cut-off value and the assay acceptance criteria. A mean value of a test sample equal to or greater than the cut-off value is considered positive.

COMPLEMENT FIXATION TEST

Complement fixation has selective value in allowing for simultaneous assay of antibodies to a wide variety of viral agents. The procedure involves multiple variables consisting of two pairs of antigen-antibody reactions. The first reaction, between a known virus antigen and a specific antibody in the test sample, takes place in the presence of a predetermined amount of exogenous complement. The complement is removed by the antigen-antibody complex. The second antigen-antibody reaction consists of sheep red blood cells (SRBCs) and hemolysin (antibody against SRBC). When this indicator system is added to the reaction mixture, the sensitized SRBCs will lyse only in the presence of free complement. The extent of lysis of SRBCs is inversely correlated with the amount of the antibody in the test article.

The experimental procedure involves the optimal titration of concentrations of hemolytic serum, complement, and viral antigen, using chessboard format. If used as the test sample, human serum should be inactivated at 56° for 30 minutes to inactivate the endogenous complement activity. A number of important controls must be run along with the test, and results must be within limits before the test can be properly interpreted. These include the sensitivity of SRBCs to lysis and complement concentration used. The relative amount of virus-specific antibody present can be determined by testing serial dilutions of the serum or product. The *complement-fixing titer* is the reciprocal of the highest dilution that prevents 50% hemolysis.

NEUTRALIZATION FOR ANTIBODY DETECTION

Neutralization for the measurement of antibodies to viral agents is still one of the most valuable assays available because of its high specificity and its ability to detect neutralizing antibodies. Neutralization is defined as the loss of viral infectivity through the binding of specific antibodies to viral coat proteins (or envelope glycoproteins) on the surface of the infectious viral particle. The assay may be used to measure the presence of antibodies to a known virus in a serum or product sample, or conversely to identify an unknown virus by using a serum or product sample containing known antibodies.

Before performing a neutralization assay to measure the presence of antibodies in serum or product, a known virus must first be grown and titrated in the test system in which the neutralization assay will be performed. For viruses prepared in cell culture, this usually involves inoculating susceptible cultures with relatively low multiplicity of infection (MOI; <1 PFU per cell) and harvesting the infected cells when about 50% to 75% cytopathic effect (CPE) is demonstrated. The virus preparation is then titrated by preparing serial multifold dilutions and inoculating replicate tubes or plate cultures with a fixed volume of the virus preparation. The endpoint of the titration is the dilution of the virus that will infect 50% of the cell cultures inoculated. This endpoint is said to contain one 50% tissue culture infective dose (TCID₅₀) in the volume used. If the test system involves animal lethality, the endpoint is referred as one 50% lethal dose (LD₅₀). The amount of virus used in the neutralization assay to follow is typically standardized to contain 100 TCID₅₀ or LD₅₀.

The test or host system used in neutralization assays is chosen on the basis of the specific virus to be tested and its

ability to replicate in the system. The commonly used host systems include cell culture, embryonated chicken eggs, and mice. Cell culture is usually the preferred test system, because the viruses used in the neutralization assay usually readily replicate and produce CPE. Susceptible host cells are grown in monolayers in dishes or multiwell plate cultures. After the virus/neutralizing serum mixture is added, the cultures are overlaid with agar-containing medium to restrict spread of CPE and allow development of viral plaques. The prevention of plaque development is indicative of the presence of neutralizing antibody. Alternatively, neutralization can be performed in tube monolayer cultures or even in suspension tissue culture. Embryonated eggs may be used when the virus to be used or tested does not produce plaques in tissue culture systems. The route of inoculation and the endpoint depend on the virus.

Neutralization assays may be set up in various ways, depending on the specific virus of interest and the serum or product to be tested for neutralizing activity. In general, a fixed amount of infectious virus is preincubated with undiluted and serial dilutions of serum or product to be tested for neutralizing activity and separately with preimmune serum or control product; this approach is referred to as the *constant virus-varying serum* method. Following preincubation, the mixtures are separately injected or added to the test system. Reduction in infectivity between test and control serum or product is scored in various ways, depending on the test system. The endpoint of the assay is generally defined as the highest dilution of the serum or product that neutralizes one-half of the initial viral inoculum, as calculated by Reed-Muench or the Spearman-Kärber method.

The titer of neutralizing antibody in the test serum or product is the reciprocal of the highest dilution that completely inhibits CPE or other virus effect in the test system. This dilution is said to contain 1 neutralizing antibody unit per unit volume used in the titration. When a serum or product known to contain neutralizing antibody is used in an assay to determine the identity of an unknown virus, 20 neutralizing antibody units in a fixed volume are generally used in the assay. Positive and negative control sera must give expected reactivity in the assay.

HEMAGGLUTINATION INHIBITION (HAI)

A number of enveloped viruses, including the influenza and parainfluenza viruses, acquire protein receptors capable of binding RBCs (hemagglutinins) of various animal species on their surface as they bud through infected cell plasma membranes during viral maturation. In addition, some nonenveloped viruses such as adenoviruses and certain enteroviruses have hemagglutinin proteins in their outer capsid. This property allows for detection of a specific virus in a sample if a known specific antibody to the virus is available. Alternatively, the presence of antibody specific to the virus can be detected and quantitated by its ability to inhibit hemagglutination. This is the principle of the hemagglutination inhibition (HAI) test.

The HAI test for antibody is performed by making serial dilutions of the specimen to be tested and mixing the dilutions with a fixed amount of the virus or specific viral hemagglutinin protein in a tube or microtitration plate format. Indicator RBCs from the appropriate animal species are added, the suspension is mixed, and the tubes or plates are allowed to stand for a predetermined period. If specific antibody is present, the virus will bind and the RBCs will not agglutinate; they will settle to the bottom of the tube or plate and form an RBC "button". If specific antibody is absent, the RBCs will be agglutinated by the virus and form a diffuse film. The titer of the serum or product is the reciprocal of the dilution that completely inhibits agglutination.

HAI is very useful for subtyping influenza virus isolates. A number of factors contribute to the potential variability of

the HAI test. Certain serum samples and products may contain nonspecific inhibitors of RBC agglutinins, which may yield false-positive results. A number of procedures have been developed to remove such inhibitors, including adsorption and heat inactivation procedures. Specimens may also contain RBC agglutinins other than specific antibody, and these may contribute to false-negative results. Appropriate preparation and titration of reagents, including RBCs and viral hemagglutinin stocks and suspensions, is critical. In addition, controls for nonspecific agglutination or inhibitors of agglutination must be included in every assay.

WESTERN BLOT (OR IMMUNOBLOT) ASSAY FOR ANTIBODY DETECTION

The immunoblot, or Western blot, assay is a technique for the simultaneous detection of antibodies to various protein antigens of a given virus. The term *recombinant immunoblot assay* (RIBA) is applicable when the starting protein mixtures are recombinant proteins obtained from prokaryotic or eukaryotic expression systems instead of crude or partially purified virus from infected cells. The method is often used diagnostically as a supplementary or confirmatory test in situations where an initial assay for antibody lacks sufficient specificity or is known to be prone to false-positive results. This is especially important when the test is being used to diagnose an infection of clinical significance such as HIV or HCV infection.

A number of commercial immunoblot kits are available, particularly for viruses such as HIV and HCV; several have regulatory approval for diagnostic use. Alternatively, viral antigen preparations may be produced in-house or purchased, along with other reagents required for the assays. Careful control and/or sourcing of these reagents are critical to ensuring that compliance requirements are maintained.

For selected viral agents, there are generally accepted interpretive standards for the analysis of reactivity or positive results in an immunoblot assay. However, the presence of nonspecific bands may be due to antibody reactivity to cellular protein antigens caused by autoimmune diseases and/or the use of crude virus-infected cell proteins as antigen in the assay. Indeterminate reactions may also occur if only a limited number of specific antibody bands are observed.

Appropriate positive and negative control sera must be included in each assay and reactivity must be scored for both the presence and the intensity of expected protein bands.

Application of the Antibody Detection Methods to Specific Viruses

Human blood-borne pathogens that may be present in infectious form in human donated blood used directly in the production of biological products are a concern because they may present a risk of transmission to others. Testing for virus-specific antibodies in donated blood serves as a screening procedure for the elimination of suspect units. Alternatively, the viruses may represent important agents for which human vaccines have been or are being developed. Thus the ability to detect virus-specific antibodies in an immunized individual or animal model may be important for demonstrating the efficacy of the vaccine. Currently, in the United States, a number of FDA-approved screening or definitive tests may be conducted on donated units of blood for evidence of the presence of agents of infectious diseases, including hepatitis B and C viruses, human immunodeficiency virus, and West Nile virus. In addition, plasma sent for fractionation before production of plasma-derived products is required to be tested for hepatitis A virus (HAV) and human parvovirus B-19.

GLOSSARY

Acceptance Criteria—Anticipated results, which may be numerical limits, ranges, or other characterization for the tests described. They establish the standards to which a drug substance or drug product should conform in order to be considered acceptable for its intended use.

Adventitious Agent—Acquired accidental contaminant in a cell line such as viruses and toxins; the agent is often infectious.

Amplicon—A segment of DNA generated by the PCR process whose sequence is defined by forward and reverse primers.

Antibody—An infection-fighting protein molecule that binds, neutralizes, and helps destroy foreign microorganisms or toxins. Also known as immunoglobulins, antibodies are produced by the immune system in response to antigens.

Antigen—Any agent that induces the production of an antibody and reacts specifically with it.

Assay Validation—A formal, archived demonstration of the analytical performance of an assay that provides justification for use of the assay for an intended purpose and a range of acceptable potency values.

Bioassay—Analytical method that uses living animals, cells, tissues, or organisms as test subjects.

Biologics—Products such as antitoxins, antivenins, blood, blood derivatives, immune serums, immunologic diagnostic aids, toxoids, vaccines, and related articles that are produced under license in accordance with the terms of the federal Public Health Service Act (58 Stat. 682) approved July 1, 1944, as amended, have long been known as “biologics.” However, in Table III, Part F, of the Act, the term “biological products” is applied to the group of licensed products as a whole. For Pharmacopeial purposes, the term “biologics” refers to those products that must be licensed under the Act and comply with Food and Drug Regulations—Code of Federal Regulations, Title 21 Parts 600–680, pertaining to federal control of these products (other than certain diagnostic aids), as administered by the Center for Biologics Evaluation and Research or, in the case of the relevant diagnostic aids, by the Center for Devices and Radiological Health of the federal Food and Drug Administration. [Definition from *Biologics* (1041), *USP–NF* vol. 30 (2007), p. 414.]

Biotechnology-Derived Product—Macromolecular article derived from biotechnology processes such as recombinant DNA (rDNA) technology, hybridoma technology, and the like.

Bulk Harvest—See *Unprocessed Bulk Harvest*.

Capsid—The outer protein shell of a virus particle.

Cell Bank—A defined population of cells, such as an immortalized cell line, grown by a defined process and cryopreserved in a defined process and within a defined passage number range. The assumption is that each vial from a cell bank is comparable and that when thawed and added to a manufacturing vessel (or an analytical assay), it will perform in a consistent way.

Chaotropic—A reagent that causes molecular structure to be disrupted; in particular, those formed by noncovalent forces such as hydrogen bonding, van der Waals interactions, and the hydrophobic effect.

Complement—A group of proteins in the blood that work in concert with other immune system proteins and cells (such as antibodies) in attaching foreign substances.

cDNA—Complementary DNA. Two strands of nucleic acid that can hybridize by specific base pairing between the nucleotides.

Confluency—Refers to the point when 100% of the surface area of the vessel is covered in cells.

Cryopreservative—Reagent used to keep a cell alive in deep-frozen condition (usually in liquid nitrogen).

Cytopathic—Damaging to cells, causing them to exhibit signs of disease or cell death.

ELISA—Enzyme-linked immunosorbent assay. A biochemical technique used to detect the presence of an antibody or an antigen in a sample.

Endpoint Assay—An analytical method that measures the amount of accumulated product at the end of the assay.

Epitope—A molecular region on the surface of an antigen that is recognized by an antibody and can combine with the specific antibody produced by such a response; also called a determinant or an antigenic determinant.

Glycoprotein—Protein that contains sugar side chains added as a posttranslational process; the presence of sugar side chains often affects activity, antigenicity, and in vivo stability.

Host Cell Tropism—The range of susceptible cells that a particular microorganism can infect.

ICH—The International Conference on Harmonization of Technical Requirements for Registration of Pharmaceuticals for Human Use.

Limit of Detection (LOD)—The lowest concentration of an analyte in a sample that can be detected, not quantitated. It is a limit test that specifies whether or not an analyte is above or below a certain value. It is expressed as a concentration at a specified signal-to-noise ratio, usually 2 or 3.

Mycoplasma—Parasitic microorganism that infects mammalian cells, possessing some characteristics of both bacteria and viruses. Prokaryotic microorganisms belong to the family *Mycoplasmataceae*, with no cell walls. They may grow attached or close to cell surfaces in the cytoplasm and subtly change the properties of the cells.

Passage—An operational procedure used to feed cultured cells, usually by providing fresh medium and dilution of cells in a new culture vessel. The number of such operations is referred to as the passage number. It is not the same as cell generation number, which is strictly related to cell doubling time.

qPCR—Quantitative polymerase chain reaction. A modification of the polymerase chain reaction used to measure the quantity of DNA, complementary DNA, or ribonucleic acid present in a sample. Like other forms of polymerase chain reaction, the process is used to amplify DNA samples via the enzyme DNA polymerase.

Raw Materials—All components used to manufacture a drug substance or drug product; regulated by 21 CFR 211.

RT-PCR—Reverse transcriptase polymerase chain reaction. A variation of the PCR technique in which cDNA is made from RNA via reverse transcription. The cDNA is then amplified using standard PCR protocols.

Serotype—The kind of microorganism as characterized by testing for recognizable antigens on the surface of cells of the microorganism.

Spiking—Adding a known amount of analyte from a laboratory standard acting as a tracer to check a method for recovery or accuracy.

Syncytium—A multinucleated mass of cytoplasm that is not separated into individual cells.

System Suitability—The checking of a system to ensure system performance before or during the analysis of unknowns. Parameters such as plate count, tailing factors, resolution, and reproducibility are determined and compared against the specifications set for the method. These parameters are measured during the analysis of a system suitability *sample*, which is a mixture of main components and expected by-products.

TCID₅₀—50% tissue culture infective dose. The level of dilution of a virus at which half of a series of laboratory wells contain active, growing virus.

Unprocessed Bulk Harvest—The pooled harvests of cell culture fluids that constitute a homogeneous mixture for manufacture into a unique lot of product.

<1238> VACCINES FOR HUMAN USE—BACTERIAL VACCINES

INTRODUCTION

An overview of vaccines for human use is presented in *Vaccines for Human Use—General Considerations* (1235). Bacterial vaccines can be derived from whole cells, either killed or attenuated in their ability to cause disease, or from some component(s) of the intact cell that are important for virulence or damage to the host. Another subset of bacterial vaccines, derived from toxins, is the toxoids. Bacterial vaccine products can be mixtures of components from different species, from different strains or different serotypes of the same species, or from different components from cells of the same species.

The simplest bacterial vaccines consist of the purified cell-surface capsular polysaccharides (CPS) from organisms such as *Salmonella enterica* serovar Typhi, various meningococcal serogroups, or pneumococcal serotypes that cause meningitis, otitis media, acute respiratory infections, and pneumonia. Although the typhoid vaccine consists of a single polysaccharide, the meningococcal vaccines contain as many as four serogroup-specific CPS, and the pneumococcal vaccine contains 23 serotypes.

The immunological response to meningococcal and pneumococcal polysaccharides, and to the capsular polysaccharide from *Haemophilus influenzae* type b (Hib), is improved by covalent attachment of the CPS or an oligosaccharide derived from it to a suitable carrier protein. The immunological response to these glycoconjugate vaccines is elicited via immunologic pathways different from those induced by purified polysaccharides, creates a T-cell-dependent response, and establishes immunological memory. The carrier proteins are typically bacterial toxoids or bacterial outer membrane protein vesicles but may also be from other sources. For

these products, anti-CPS antibodies appear to be sufficient to protect against disease, although the glycoconjugate vaccines also may reduce carriage of the organisms in the nasopharynx. Due to the complexity of their manufacturing processes, glycoconjugate vaccine products tend to contain fewer serotype or serogroup components than do the related purified polysaccharide vaccines.

Many bacterial pathogens, including those that cause diphtheria and tetanus, produce toxins that kill tissue. Immunological neutralization of these toxins is sufficient to prevent disease. These subunit vaccines consist of chemically detoxified toxins (toxoids) purified from culture supernatant and are capable of eliciting neutralizing antibodies against the native toxin. Other types of purified subunit and purification processes may be developed.

Although earlier pertussis vaccines consisted of myriad chemically inactivated whole-cell and toxin components, current acellular products contain various combinations of specific purified proteins, sometimes toxoided (e.g., fimbriae and other cell-surface protein components). Compared to older products, these vaccines apparently produce protection by a different mode of action but have a lower incidence of adverse events. A combination of diphtheria and tetanus toxoids and an acellular pertussis vaccine form the core components of many polyvalent pediatric and adult combination vaccines. To these may also be added an Hib glycoconjugate, hepatitis B, and/or inactivated poliovirus immunogens.

Live attenuated bacterial vaccines are currently limited to *Bacillus Calmette-Guérin* (BCG), which protects against tuberculosis when administered through the skin, and the *S. typhi* Ty21a construct, which is an oral vaccine against typhoid fever.

The immune response against these bacterial polysaccharide and protein antigens can be increased by inclusion of adjuvants. The primary adjuvant licensed in the United States is based on aluminum salts such as aluminum hydroxide and aluminum phosphate, although development and characterization of new adjuvants is an active area of research.

RAW MATERIALS

Raw materials can directly affect the identity, strength, purity, and quality of bacterial vaccines. A consistent manufacturing process critically depends on use of consistent raw materials (e.g., during seed banking, fermentation, harvest, purification, and formulation; see *Vaccines for Human Use—General Considerations* (1235)). Raw materials for bacterial growth media typically consist of both well-defined chemical entities (e.g., amino acids, carbohydrates, vitamins, minerals) and more complex components (e.g., protein hydrolysates, yeast extracts, peptones). Manufacturers should consider the source of each of these raw materials to ensure that they come from reliable vendors who adhere to cGMP quality standards and can assure a long-term supply. Manufacturers should communicate with raw material vendors in order to avoid any changes in the sourcing or manufacture of components and to avoid supply shortages. Without such communications, the consistency of the fermentation process and the supply of the vaccine can be adversely affected. Consistent raw materials are particularly critical for more complex fermentation components such as yeast extract or peptones for which changes may be difficult to detect but are likely to have a direct effect on fermentation.

Accurate records of the composition and source of the culture medium used in seed banking and routine fermentation should be maintained and also document release criteria for raw materials or components. Manufacturers should determine if any of their raw materials are derived from animal origin. If additives from animal sources are added to the culture medium, they should be certified to be free from contaminants and adventitious agents such as those that cause bovine spongiform encephalopathy or transmissible

spongiform encephalopathy. Vendors/manufacturers should provide information about the identity and source of additives and should test for adventitious agents. Use of antibiotics should be minimal or should be avoided to ensure that no unwanted antibiotics are included in the drug product, unless they are intentionally used in manufacturing (e.g., as selective markers).

As manufacturers scale up fermentation to pilot production (i.e., within tenfold of final manufacturing scale), they also should ensure, to the extent possible, the availability of multiple sources for all raw materials. This will ensure that supply or business instabilities at one vendor do not become the limiting factor in vaccine manufacture.

CELL BANKS

Source and History

The source of cells used in cell banks should be documented. The original isolate should include, when possible, the age, sex, and species of the donor; the donor's medical history; and, if available, culture history including methods used for the isolation of the substrate bacteria.

The source of cells from which the strain was derived is to be stated, and relevant references from the scientific literature should be cited. The source should generate a sufficient amount of antigen(s) to meet the medical need. Information obtained directly from the source laboratory is preferred. When this is not available, literature references can be used to provide bacterial classification (i.e., genus, species, and strain designation) and specific phenotypic and/or genotypic trait. For microbial-expression systems such as *E. coli* or *S. pneumoniae*, the manufacturer should describe the method used to prepare the DNA coding for the protein, including the cell and origin of the source nucleic acid. All propagations carried out with the original isolate should be documented and should include, as applicable, the method used for subculture, any use of animal-derived material, record of subcultivations, and storage conditions. Constituents of the culture medium must be described, in particular, materials of human or animal origin such as serum, enzymes, hydrolysates, or other living cells.

For microbial-expression systems, the steps in the assembly of the expression construct must be described in detail. This description should include the source and function of the component parts of the expression construct (e.g., origins of replication, antibiotic resistance genes, promoters, enhancers, and whether or not the protein is synthesized as a fusion protein). Manufacturers should provide restriction endonuclease digestion maps that illustrate the sites used in preparing the expression construct and sites used in identification of DNA fragments.

A complete nucleotide sequence analysis of the expression construct's coding region for the protein of interest should be performed. The sequence analysis should be provided and should include a complete annotation designating all of the important sequence features. The copy number and physical state of the expression construct should be determined.

Cell Bank Lineage and Genealogy

A flow chart can be used to demonstrate the preparation of the cell bank lineage from the original source, through preliminary cell banks (or process development cell banks, as applicable), to the Master Cell Bank (MCB) and production Working Cell Banks (WCB).

Manufacturers should describe their strategy for providing a continued supply of cells from their cell bank(s), including the lot size and anticipated use rate of the cell bank(s) for production, the expected intervals between generation of new cell bank(s), and the criteria for qualification of cell

bank(s). If multiple WCBs were used for clinical trials, process validation, or commercial supplies, flow charts can help illustrate the common source (i.e., MCB) from which the WCB were derived.

Once an MCB is produced, a cell bank system should be generated to prevent unwanted drift that might ensue from repeated subcultures or multiple generations. The system should ensure that an adequate supply of equivalent cells exists over the entire life span of the product. Ordinarily, the cell bank system consists of two tiers: an MCB and a series of WCB derived from the MCB. When additional tiers of WCBs are prepared, manufacturers should clearly identify the generation that will be used for WCB.

Cell Bank Manufacture

Generally, the MCB is made from a preliminary cell bank derived from the original source or directly from an initial clone. Manufacturers generally prepare cells for banking by expanding cultures in a progressively greater number of vessels or in larger vessels until a pool of cells is obtained. If manufacturers use more than one vessel, they can ensure the uniform composition of the contents by combining the cells from all of the culture vessels.

For microbial-expression systems, a single host cell that contains the expression construct is propagated to generate the MCB. Manufacturers should document the cell cloning history and method of transferring the expression construct into the host cell. They also should completely describe methods and criteria used to amplify the expression construct and to select the cell clone for production.

The process for WCB used in clinical trials and for commercial supply should be similar to the MCB process. A WCB is derived from one or more containers of the MCB and is typically used to directly provide cells for the manufacturing process. Additional WCB are generated from the MCB as needed.

Preferably the MCB and WCB should be prepared in a similar manner, but the MCB and WCB may differ in certain respects (e.g., culture components and culture conditions). Similarly, the culture conditions used to prepare the MCB and WCB may differ from those used for the production process or between clinical trial materials or commercial supply. The preparation procedures for all cell culture processes must be described, and details of process changes must be documented. Comparability of product quality must be demonstrated when process changes occur between WCBs.

Cell banks should be made under cGMP because they are expected to last for the lifetime of the product. The facility should be operated to minimize the chance of microbial contamination and have in place procedures to prevent cross-contamination with other materials. Critical equipment used in the preparation of cell banks should be qualified. Manufacturers should establish the cell bank in a suitably controlled environment to protect both the cell bank and personnel handling it. During the establishment of the cell bank, no other living infectious material (e.g., viruses, cell lines, or cell strains) can be handled simultaneously in the same area.

Cell Bank Validation

The cell banking process should be considered a unit operation and should be validated. The process begins with the MCB vial and the cell bank process validated for preparing WCB. The suitability of WCB for intended use should be further demonstrated by the consistency and quality of successive product batches. Qualified banks should be used for process validation of fermentation, drug substance, etc. If this is not possible, then manufacturers should perform a small-scale demonstration of the appropriateness of the cell bank. The basic principles of process validation apply, in-

cluding use of validated analytical methods and stability evaluation.

Manufacturers should describe the methods used to preserve cell banks, including the cryoprotectant and media used. Storage containers (e.g., vials, ampules, and other appropriate vessels) and closure systems should be described. Container–closure systems should incorporate materials and designs that withstand storage and retrieval without breakage or leakage and are physically and chemically compatible with the stored material.

Cell Bank Testing

A newly prepared cell bank (MCB or WCB) should be evaluated by a series of appropriate release and characterization tests on an aliquot of the cell bank or on cultures derived from it, as appropriate. The amount of testing required for an MCB may influence that required for subsequent WCBs, and the extent of testing both may influence the testing needed for production cell cultures. Manufacturers should evaluate all cell banks, including bacterial cultures or recombinant bacterial expression systems, for identity, culture purity, and viability. Additionally, manufacturers should evaluate the genetic stability and consistent productivity of all cell lines.

To confirm identity, manufacturers should perform appropriate tests to determine that the banked cells are what they are represented to be. Either phenotypic or genotypic characteristics can be used in identity testing to classify bacterial strains to species level, and when applicable, supplementary serological tests can be performed. For most microbial cells and transfected cells, analysis of growth on selective media is usually adequate to confirm host cell identity. Where a variety of strains can be used, biological characterization methods such as phage typing should be considered as supplementary tests. Expression of the desired product is also considered adequate to confirm the identity of the microbial expression system.

It must also be demonstrated that cell banks are biologically pure (i.e., free from adventitious microbial agents). Testing for adventitious agents should include tests for bacteria, fungi, mycoplasmas and viruses, as applicable.

Additionally, all cell banks should be tested to confirm the viability of the cells. Viable cell counts or growth tests should be performed to demonstrate that the cell culture has sufficient viability and is suitable for its subsequent intended use.

Evaluation of genetic stability and persistence of productivity is a reflection of how many doublings the cells can tolerate without compromising their genetic integrity (e.g., plasmid retention) and productivity (e.g., mass of product per cell). Such testing is critical to ensure that the cell line performs reliably in the full course of the production process from the initial MCB stage through the longest production intended. As part of this evaluation, manufacturers should document the number of passages from the original source, the number of subcultivations from the original source to the MCB, from the MCB to the WCB, and from the WCB to the final bulk. The earliest and latest culture states (e.g., MCB and end production) should be evaluated to ensure that the desired characteristics persist. Such a demonstration of cell line stability is commonly performed once for each product marketing application.

Characterization tests may be useful for demonstrating that the cell bank is composed of cells with the intended phenotypic/genotypic characteristics. Such tests can include cellular and colony morphology (i.e., use of selective and/or differential media), biochemical profiles (enzymatic activity or substrate utilization), immunological identity, characteristic growth, and antibiotic susceptibility.

Additionally, for recombinant bacterial expression cell lines (e.g., *E. coli*) molecular characterization testing can include DNA sequencing of the target gene sequence along with the flanking regions, expression construct retention, and

plasmid copy number. Analysis of the expression construct at the nucleic acid level should be performed with consideration that this verifies only the coding sequence of a recombinant gene. Restriction endonuclease mapping or other suitable techniques should be used to analyze the expression construct for insertions or deletions and for the number of integration sites. For extrachromosomal expression systems, the percent of host cells that retain the expression construct should be determined under selected and non-selected growth conditions. For cells with chromosomal copies of the expression construct, the nucleotide sequence encoding the product could be verified by recloning and sequencing of chromosomal copies.

Much of this testing should be conducted on the MCB if possible, which will preclude the need to repeat much of the testing on each WCB or production lot, although sometimes redundant testing (on both MCB and WCB) may be desirable.

Limited identity testing is generally performed on each WCB if extensive identity testing was performed on the MCB. For recombinant products, the identity of the WCB should be assessed by restriction endonuclease mapping of the expression construct for copy number and for insertions or deletions. In addition, where appropriate, the WCB should be identified by phenotypic characterization (e.g., auxotrophy, antibiotic resistance).

For each lot of WCB derived from the MCB, manufacturers should routinely test for contaminants that may have been introduced from the culture medium during preparation. Purity tests like those performed on the MCB to test for adventitious agents may be performed on the WCB.

Characteristics of the recombinant protein product can also be applied (see below) as another means of defining the ultimate output of the cell line.

In the event that a new MCB is needed, the testing performed on a new MCB should be the same as that performed on the original MCB unless justified. If a new MCB is to be generated by expression construct transfer into host cells followed by clonal selection, then acceptance criteria for both the new clone and the protein produced by the clone should be described and justified.

Cell Bank Storage

In both MCB and WCB of the same product, similar containers (such as cryovials) are generally used and are treated identically during storage.

The location, identity, and detailed inventory of individual ampules of cells should be thoroughly documented with procedures that allow the cell bank containers to be traced. Labeling should clearly indicate the biological name of the components, unique container number, lot or batch number if applicable, and the type of bank (such as MCB or WCB). The label must withstand storage and retrieval without loss of integrity or information.

Cell banks should be established, stored, and used in a way that minimizes the risk of contamination or cross-contamination by other cell types that may be present in storage. Once issued, banked materials cannot be returned to the controlled storage area. Access to banked material must be controlled by a strict inventory-control system with limited access by authorized individuals only.

Bacterial cell banks should be stored in either the liquid or vapor phase of liquid nitrogen or in mechanical freezers (generally $\leq -60^{\circ}$). Storage conditions (generally $\leq -60^{\circ}$) may be acceptable when supported by data that demonstrate that a minimum level of cell viability is maintained and is adequate for production use. Storage temperature and other critical storage conditions should be maintained within validated limits. Temperatures must be continuously monitored and recorded, preferably on an alarm system. Shipping containers used to transport cryopreserved cell banks to offsite storage facilities or manufacturing facilities

must be validated, and shipping qualification must be performed before use.

Because of more frequent usage of WCBs and to protect the MCB, the WCB should be stored separately from the MCB. Cell banks may also be stored in two or more widely separate areas within the production facility, as well as at a distant site in order to avoid loss of the cell bank (e.g., caused by equipment malfunctions or disaster at the site). When stored in different locations, the cell banks must be stored under the same conditions.

As part of a disaster recovery plan, the manufacturer should document the steps and timeline needed to restart production of new cell banks and/or contingency plans for continued manufacturing production.

Storage Stability

MCB and WCB should be placed in a stability program. Evidence for banked cell stability under defined storage conditions usually is generated during production of clinical trial material or commercial material from the banked cells. Data from the determination of cell viability when the preserved cells are reconstituted for production of clinical trial supplies can verify that the revived cells have survived the preservation process. Data from the preparation of clinical materials are used to demonstrate that the revived cells can be used to prepare the desired product.

Enough MCB material for the lifetime of the product should be put on stability (enough WCB should be put on stability to support the lifetime of the WCB). This can be a large volume because the product lifetime can be quite long (e.g., 50 years). During the preparation of the MCB, the lot size should be large enough to allow adequate inventory to support the lifetime of the stability study as well as production for the life of the product. Time points for such a long-term study might include 0, 6, and 12 months, and then perhaps every 1 to 3 years thereafter. Typically, no expiration dating is used for cell banks because stability studies are used to confirm the suitability of the material. Greater reliance is placed on the successful (and typical) culture of the cells themselves. The proposed monitoring should be documented in pre-approved protocols. The time points can be reduced (e.g., increase the time between time points) if data indicate stability. In addition, time points can be added if sufficient material is available and the data suggest that more monitoring is needed. The stability plan depends on the use rate in manufacturing.

FERMENTATION

Production of the drug substance for a bacterial vaccine requires a fermentation process that is consistent and sufficiently productive to support commercial production. The approach to achieving this has become fairly standardized and provides a relatively high probability of success for early batch production to support a development program. It is still a significant challenge to achieve sufficient productivity to support commercial manufacture of a licensed product. Directly following any fermentation process is the harvest process, which serves as a transition step between biomass expansion and downstream process steps. For purposes of this chapter, harvest will be considered as an extension of the fermentation process.

Fermentation Starting Materials: Cell Inoculum

The cell inoculum for the fermentation process is the single most important component for establishing a reproducible fermentation process. In early development before finalizing fermentation conditions, manufacturers typically must generate an interim source of this inoculum, a Process Development Cell Bank (PDCB). The origin of the PDCB should be a clonal isolate of the original transfected or isolated

strain that demonstrates suitable growth properties and produces the antigen of interest in sufficient quantity and quality for the intended purpose. The use of a clonal isolate ensures that the genetic starting point for each batch is the same and that subtle variations in process conditions will not inadvertently allow one population versus another to dominate the culture. That is, the PDCB is used for fermentation development to ensure that variations in the fermentation conditions can be interpreted without the overlay of competition between populations of transfectants.

Initial development of the fermentation process, preferably with the PDCB, typically precedes production of the MCB and WCB. Best practice is to derive these cell banks from the same clonal isolate as the PDCB in order to reduce the need for a second cycle of fermentation development when the WCB is deployed. Substitution of a WCB for the PDCB at the final stages of fermentation development is common practice, but care must be taken to constrain such experiments to optimization of the fermentation process. More detail is found in the cell banks section above.

Fermentation Hardware

The biomass production process typically begins with a small-volume inoculum in an initial fermentation volume that is 20- to 100-fold larger than the initial inoculum volume. This initial passage is often followed by one or more intermediate fermentations that expand the production volume by 20- to 100-fold at each step until the production fermentation volume (typically 500–3000 L) is reached. Routine manufacture at these scales requires well-controlled fermentation conditions and physical facilities that meet the economic and cGMP needs for a successful product.

Bacterial fermentations have traditionally been carried out in glass, glass-lined, or passivated stainless steel fermenters that comply with cGMP requirements, particularly when using large fermenters (e.g., those with >1000 L working volume) because of containment issues with such large volumes of liquid. Traditional fermentation systems require hard-piped control systems that meet the need for clean-in-place and steam-in-place capability. The bioburden and complexity of the facility are increased if the fermentation operations must accommodate multiple product lines as well.

Smaller fermentation batches are increasingly performed in disposable bioreactors such as single-use bags with completely disposable product contact surfaces, including sensors and probes. These systems are becoming readily available, are less expensive, and are more flexible than fixed equipment and meet the needs of the competitive business and evolving cGMP expectations and requirements. A note of caution is warranted, though, because this disposable technology can lead to changes in the material of product contact surfaces. Such changes then require re-evaluation and sometimes revalidation of the manufacturing process for late-stage development and commercial products. Thus the reduced cleaning burden may bring an increase in the need for extractability and leachability studies.

Harvest Hardware

Harvest of the fermentation product can focus on recovery of either the wet cell mass from which the product will be extracted or the fermentation broth from which the product will be directly purified. In the former case, centrifugal separation is typically employed. Production-scale centrifuges can be either closed operations with a fixed volume of input and manual recovery of the pellet or continuous-flow operations that automatically eject and recover the clarified supernatant and/or the accumulated pellet. Although centrifuges are efficient in harvesting a fermentation product, shear forces can have significant effects on the product stream (e.g., lysed cells, sheared molecules in solution). Alternatively, and particularly when the product is se-

creted into the solution rather than retained in the cells, membrane filtration systems may be used to clarify the product stream for subsequent purification. Tangential-flow and depth filtration systems can be effective means of recovering soluble product with less concern about shear forces.

In all cases, monitoring the processing of the fermentation output and solids removal from the liquid matrix can be simple but effective means to monitor process consistency and comparability. Off-line tools such as high performance liquid chromatography (HPLC), sodium dodecyl sulfate–polyacrylamide gel electrophoresis (SDS–PAGE), or Western blot analyses can track product integrity issues such as aggregation or proteolysis.

Process Development

A productive, robust fermentation process is the result of careful consideration of a broad collection of variables, considered alone as well as in conjunction with product design and downstream processing. Fermentation process variables include chemical inputs (e.g., carbon sources, minerals, vitamins, trace elements, antifoam, and gases), physical inputs (e.g., temperature, mixing, and pH), and biological processes (e.g., nutrient utilization rates, metabolite levels, and inductors [quantity/type/addition duration]).

Product Requirements

A critical consideration in process development is anticipating how much of the product will be needed. Too little product caused by operating at too small a scale imposes supply constraints and often postlicensure urgency to scale up the process. In contrast, too much product results in excess inventory, expiring lots, infrequent manufacturing (itself a problem), and generally poor economics. A clear market evaluation is needed before one designs the manufacturing process or commits to a process for scale-up or -down.

Process Design

If one has a reasonably defined production need and an initial estimate of product yield, one can extrapolate the scale of the fermentation from the volume (yield), production frequency, and the expected productivity. Commercial fermentation of bacterial cultures is routinely carried out in volumes as large as 3000 L, but larger volumes are also in use. A few large lots per year can be advantageous for a very robust process but may be limited by downstream process capabilities and/or the stability of the fermentation product as a production intermediate. An additional consideration may be the difficulty in generating enough lots to ensure that the fermentation process is indeed robust. Failure of a large lot carries important financial and inventory risks.

A large number of lots can impose logistical problems if turn-around time is too tight or coordination of downstream events becomes too complex. Logistics includes quality control testing, which depends on the number rather than the size of lots. Production that involves a large number of smaller lots can also require blending of multiple intermediate lots in order to produce a final drug product lot. This can cause challenges if product-related problems occur and may entail root-cause investigations. In general, appropriate fermentation sizing results in a process that has a turn-around time of less than a week, that can be accommodated with one or a few purification runs, and that results in one to several fills of final product after each purification cycle.

Early Development Considerations

During early development of a biological product, the most important fermentation considerations are an appropriate, well-defined MCB and a fermentation process that is reasonably productive, reproducible, and scalable. The latter is often underestimated when one considers the physical, chemical, and biological control of the process as process volumes change by orders of magnitude.

The mechanics of the fermentation process are an important consideration. Fermentations are typically studied in shake flask experiments or even microscale reactors that can readily accommodate many experiments conducted in parallel. Although this is attractive for initial identification of process conditions, the ultimate culture vessel should be a controlled fermenter where growth conditions can be controlled and monitored in a more rigorous and complete manner. Manufacturers should begin work in small-scale fermenters as early as possible to ensure that robust, controlled experiments can be run to refine the initial fermentation conditions.

Fermentation harvest processes also should be scalable. Although it is possible to scale centrifugation conditions, it is a challenge to maintain equivalent centrifugal conditions, particularly in a flow-through mode. Filtration processes can usually be scaled more predictably provided the membrane manufacturer is anticipating the needs of the process development scientist.

When manufacturers define a process, they should evaluate its robustness by purposeful deviations such as changes in sources of raw materials and time and temperature limits of unit operations. Such evaluations better define the rationale for setting process limits and for knowing which are most critical to the success of the manufacturing process.

Process Monitoring

On the basis of early development process characterization data, manufacturers should be able to identify key analytical measures that, if applied to all lots, can either verify the correct progression of the process or serve as a sentinel to determine whether a specific batch is showing signs of deviating from the typical profile. In the absence of such data, an aberrant process may go unnoticed or may not be detected until testing of a process intermediate shows either an out-of-trend or out-of-specification result.

For a fermentation process, many critical variables (e.g., optical density, pH, and specific nutrient levels) can be measured online and in real time to potentially allow intervention to bring a given process back into normal range or at least to identify the point in the process at which the deviation occurred. Such data can be valuable in identifying potential process improvements. Conversely, in the absence of such data troubleshooting can be a challenging and protracted process.

Scale-up

Just as early development requires a focus on small-scale operations, scale-up becomes essential at some point to ensure that sufficiently large lots can be made to meet program needs. As these needs become increasingly complex, larger lots are essential to ensure that multiple experiments and observations can be tied to the same lot of product, which in turn is critical to understanding critical process and product variables. If proper process engineering considerations were taken into account at the smaller production scale, scale-up can usually be done in increments of ten-fold in volume with reasonable expectation that significant process performance or product changes will not be seen. This approach may require adjustments at an intermediate scale if the initial fermentation was based on too small a volume

or if the final production scale is very large. Again, process monitoring data can be very helpful in evaluating the success of the scaled-up process.

If clinical development studies are performed at less than full manufacturing scale, as they usually are, manufacturers will be obliged to relate the comparability of the process performance and the product characteristics at the different scales. Analytical data can be compelling, but in their absence or in the presence of differences, manufacturers must demonstrate that scale-related differences are not clinically significant. However, the use of comparability protocols for scale changes will have to be approved by the local regulatory authority. In order to avoid fixing something that is not broken, analysts must take care to isolate differences caused by fermentation scale-up from changes caused by harvest or purification scale-up. One way to accomplish this is to compare process intermediates obtained, as possible, during the fermentation and harvest processes. As an example, online monitoring of fermentation conditions such as pH or glucose level can be used to demonstrate similarity during the time course of the fermentation. Similarly, measurements at the end of the fermentation process (e.g., final cell density, cell viability) and intermediate measurements during harvest (e.g., turbidity of clarified broth, wet cell mass in the pellet) provide useful information for evaluating the similarity or differences during scale-up.

PURIFICATION

A general overview of purification for bacterial derived vaccines is presented in *USP Vaccines for Human Use—General Considerations* (1235). In addition to a description of critical processing equipment, reagents, and processing steps, manufacturers should provide the rationale for the purification process chosen for component antigens recovered from the crude harvest. As with the other processes, analysts should consider the source of all raw materials and ensure that they come from reliable vendors who adhere to cGMP and can ensure a long-term supply. The cGMPs will apply to late-stage clinical supplies and commercial materials. The removal of nonproduct-related impurities (e.g., processing reagents, endotoxin, contaminating cell proteins or nucleic acids, and other residual contaminants) should be verified.

The drug substance can be one of several types of compounds: e.g., polysaccharides (wild type or modified), proteins (wild type, mutant, toxoids, or recombinant), or products of conjugation of polysaccharides and proteins, or products of conjugation of peptides and proteins.

To define and control purification processes for drug substance and drug products, the manufacturer should establish targets for process parameters and tolerances for all critical process steps including yields, activity, and purity to ensure efficacy, safety, and consistency of the final product. Requirements for pooling, if applicable, should be established. The requirements and conditions for storage of intermediates, bulks, and final containers must be established by an official stability program. The use, reuse, regeneration, and cleaning of all drug product/drug substance contact equipment (e.g., filters, chromatographic columns and resins, tanks, and process lines) should be validated. In addition, extractable/leachable studies should be performed for all product contact equipment (e.g., disposable bag systems, chromatographic column resins, and process lines).

Polysaccharide Purification

The purification steps for polysaccharides depend on the phenotype (e.g., gram negative or positive), polysaccharide presentation (e.g., membrane bound or excreted within the supernatant), and the chemical nature of the polysaccharide itself [e.g., idealized backbone linkages (glycosidic bond, phosphodiester bond), overall charge, types of charge

groups, and types of side group modifications (O-acetyl, uronic acid, sialic acid, N-acetyl, pyruvate, or O-methyl)]. Polysaccharide harvest methods determine clarification and downstream purification requirements. Clarification methods depend on whether it is necessary to perform cell lysis or only to separate cell-free broth from cellular debris. Harvest techniques include centrifugation, depth filtration, tangential-flow filtration, microfiltration, sizing filtration, or a combination of techniques. The culture may be inactivated or residual contaminants removed by selective precipitation (e.g., protein denaturation) using heat or chemical treatments (e.g., salts, detergents, enzymes, or phenol). This may require cold-storage settling before clarification.

Methods for postclarification polysaccharide precipitation are used both for isolation and purification. Fractional precipitation methods are based on overall charge or cationic binding affinities of the polysaccharide (e.g., alcoholic precipitation, ion-exchange chromatography). Agents such as cationic detergents, salts, and solvents can be used to differentially precipitate charged species from uncharged molecules. Precipitation can be performed in stepwise fashion to remove residual impurities from polysaccharide or by a series of precipitations to achieve the desired purity. Polysaccharide may be contained in either the precipitate or supernatant depending on the charge and nature of the polysaccharide. Precipitation is followed by isolation steps such as centrifugation and/or filtration during which either the precipitate is discarded or resuspended in a secondary precipitating agent until the polysaccharide is recovered. Extraction with solvents such as phenol is sometimes used to remove impurities.

An alternative and additional approach to selective precipitation methods is the use of chromatographic methods. Ion-exchange chromatography (e.g., DEAE Sepharose), hydrophobic-interaction chromatography (HIC), and gel-permeation chromatography separately and in combination have been used successfully to purify polysaccharides. At neutral pH the charge on acidic polysaccharides can be used on anion exchangers to separate acidic polysaccharides from impurities. Ion exchangers can also be used to purify neutral polysaccharides in flow-through mode, binding impurities while neutral polysaccharides flow through the column. HIC can also be used to bind impurities while the polysaccharide passes in the flow-through fraction. If there are no base-labile groups, the charge on neutral and acidic polysaccharides can be modified by addition of base to ionize hydroxyls before chromatography. The basic conditions used control the level of N-acetylation, and the polysaccharides can be re-acetylated as needed. Borate salts can be used to enhance separation during ion-exchange chromatography. A combination of precipitation, filtration, and chromatographic procedures can also be used.

Diafiltrations, ultrafiltrations, and intermediate drying steps can be used as needed to concentrate polysaccharides while removing low molecular weight impurities or replacing processing salts and solvents. The precipitates or column fractions can be further purified using suitable methods (e.g., enzyme treatments, solvent extractions, or column chromatography) to remove impurities such as nucleic acids, proteins, and lipopolysaccharides. A preliminary side group modification can also be included in the purification process (e.g., de-O-acetylation, partial depyruvylation).

The final purification step can consist of buffer exchange and filtration followed by storage of purified liquid polysaccharide (frozen) or additional final precipitation and washing of the precipitate with solvent before drying followed by storage. Drying can be performed via several types of processes (e.g., drying under vacuum or in desiccators or by lyophilization). Drying of polysaccharides can be performed in desiccators (at various temperatures) and can include several steps of grinding or fluffing and return to the desiccators for further drying. Lyophilization of polysaccharides is possible with appropriate controls if the process requires retention of bound water. Some polysaccharides may require a residual amount of moisture to maintain stability over

time. The polysaccharide is then stored under suitable conditions to avoid moisture uptake.

In-process Controls

Manufacturers identify critical process steps and perform appropriate tests to monitor the purification process. Among the latter are filter integrity tests, *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* (61), *Bacterial Endotoxins Test* (85), and other suitable tests for residues of reagents (e.g., residual reagents, solvents, enzymes, or cations) used in purification. Polysaccharide size can be influenced throughout the production process from fermentation conditions to drying conditions or by the action of mechanical stirrers, impellers, or filtration devices. If molecular size is a critical quality attribute, analysts can perform an in-process test for size (e.g., high performance size-exclusion chromatography coupled with multi-angle laser light scattering [HPSEC-MALLS]) at the appropriate process steps to monitor and control polysaccharide size. In order to demonstrate process performance and reliability, manufacturers should characterize inherent residual contaminants (e.g., protein, DNA, and endotoxins). When validation studies have demonstrated removal of residual reagents, testing of purified polysaccharides can be omitted. If material must be sterile, analysts can perform *Sterility Tests* (71).

Protein Purification

The classes of bacterial protein vaccines include toxoids, nontoxoids (e.g., pertussis antigens), naturally occurring mutants (e.g., CRM197) as carrier proteins, and engineered recombinant products.

Toxoids. At the end of fermentation, toxin-containing culture medium should be separated aseptically from the bacterial mass as soon as possible or placed in a cold room until separation can be effected. The toxin content (Lf/mL) is checked by flocculation assay using the appropriate anti-toxin standard to monitor production consistency (culture should contain NLT 40 Lf/mL). The toxin is purified first to remove any components that could cause adverse reactions in humans. A typical process includes depth filtration followed by 0.2- μ m filtration to assist in removal of cellular debris. Following preliminary purification, the toxin is then detoxified with formaldehyde or glutaraldehyde or any suitable chemical reagent by a method that avoids both destruction of the immunogenic potency of the toxoid and reversion of the toxoid to toxin, particularly on exposure to heat. Some toxoids require a single addition of formaldehyde, but others can require multiple additions. Alternatively the toxin could be detoxified and then purified or partially purified by depth filtration, detoxified by addition of an appropriate aldehyde, filtered using 0.2- μ m filtration, and then pooled. The pooled toxoid solution is further purified by clarification with activated carbon, followed by multiple ammonium sulfate precipitation steps that further fractionate and concentrate the toxoid. Typical additional purification steps include concentration, diafiltration, and/or chromatography. Purification before detoxification results in a purer product and can be advantageous if the toxoid is to be used as the protein component of a protein-carbohydrate conjugate (because copurifying high molecular weight glycan will be removed before detoxification).

During detoxification and purification, endotoxin testing according to *Bacterial Endotoxins Test* (85), and formaldehyde, protein, and irreversibility testing are performed to control and ensure consistency of the purification process. If material must be sterile, *Sterility Tests* (71) can be performed.

Proteins/Recombinant Proteins. Proteins used to make vaccines can be recombinant (in their native state or engineered to modify certain amino acids), or they can be naturally occurring mutants that have no wild-type activity yet

are capable of inducing the appropriate immune response. Proteins are harvested from the fermenter and are extracted (e.g., by mechanical and chemical disruption) then purified by suitable methods, typically consisting of filtration-concentration steps (e.g., ultrafiltration, tangential-flow filtration, diafiltration, centrifugation, selective precipitation, and even direct capture using expanded-bed chromatography or big-bead technologies). The enriched protein solution can be further purified using appropriate filtration and chromatographic steps. For all equipment that contacts drug substances (e.g., chromatographic resins, membranes, disposable bag systems, or process lines), manufacturers should assess extractables and leachables. Analysts should determine column resin life for all chromatographic systems used in the purification (including number of uses, reconditioning requirements, and storage conditions).

The type of chromatography used to purify proteins depends on the physical/chemical properties of the desired protein as well as those of other molecular entities in the harvest culture. As an example, CRM197 can be purified using a multistep chromatographic process: Production material is first diafiltered and then is separated by ion-exchange chromatography (DEAE-Sepharose) in order to purify the target protein from other molecular entities present in the purification stream. The peak of interest is collected, and ammonium sulfate is added, followed by 0.22- μ m filtration to condition the material before loading on the hydrophobic-interaction chromatography column (Phenyl Sepharose) for purification of the target protein based on its surface hydrophobicity. The peak fraction is then diluted with Water for Injection and is separated onto a ceramic hydroxyapatite column to further purify the target protein based on its surface charge. The eluted peak is then buffer exchanged into the storage buffer by ultrafiltration/diafiltration using cross-flow membrane filtration followed by 0.22- μ m filtration to yield the sterile purified concentrate.

In-process control of protein purification includes monitoring specific protein content and critical process steps as well as monitoring removal of unwanted fermentation and purification components. The pH is critical for ion-exchange chromatography, and therefore pH should be monitored. For steps designed to remove endotoxin, procedures in *Bacterial Endotoxins Test* (85) are used to monitor column eluants. Bioburden is monitored according to *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* (61) after filtration and chromatography steps. If material must be sterile, the sterility test in *Sterility Tests* (71) should be performed.

Polysaccharide-Protein Conjugates. Polysaccharide preparation and activation polysaccharides used in conjugation reactions vary in size from native high molecular weight polysaccharide to oligosaccharides produced by controlled depolymerization. Some polysaccharides can also be modified (e.g., de-O-acetylated, partially depyruvylated). Sizing/depolymerization of polysaccharides is performed in a variety of ways (e.g., acid/base catalysis, chemical oxidation/reduction, microfluidization, or mechanical treatment). Activation of polysaccharides can be performed by several different methods depending on the lability of particular epitopes under differing depolymerization conditions or the type of conjugate desired (e.g., neoglycoconjugate or lattice-type conjugate, use of a linker molecule or direct conjugation, or reductive amination). Appropriately sized and/or activated polysaccharides are purified by suitable methods that typically consist of various combinations of concentration and filtration (ultrafiltration/diafiltration) and chromatographic methods (size-exclusion chromatography, HIC).

The in-process testing performed to monitor the depolymerization and activation process depends on the process used. Typical control tests are pH monitoring and temperature monitoring of the sizing and activation reactions. The size of the polysaccharide during depolymerization can be followed by an appropriate chromatographic procedure (e.g., HPLC-SEC RI or MALLS). Testing of depolymerized

polysaccharide for select functional groups (e.g., *O*-acetyl, *N*-acetyl, or pyruvyl groups) may be required and can be determined by nuclear magnetic resonance (see *Nuclear Magnetic Resonance* <761>). In-process testing of the activated polysaccharide depends on the activation process used. For example, if reductive amination is used to attach a linker to the depolymerized polysaccharide, the control testing would include measurement of reducing activity (e.g., available reducing sugars), polysaccharide content (e.g., for determining the loading ratio in conjugation), and total and free linker content (e.g., for determining the number of active sites for conjugation). Depending on the activation and conjugation process used (i.e., immediate conjugation after activation), consistency in degree of polysaccharide activation may also be demonstrated as part of process validation or reflected by characteristics of the final conjugate bulk. The concentration/filtration steps of the purification process are monitored for conductivity to ensure removal of salts.

Conjugation. The conjugation chemistry used determines the type of conjugate made (i.e., neoglycoconjugate or lattice). The conjugate is obtained by the covalent binding of activated polysaccharides to the carrier protein. Conjugates are purified by suitable methods designed to remove residual reagents used for conjugation as well as to remove unreacted polysaccharide and protein. The removal of residual reagents is confirmed by suitable tests or by validation of the purification process. Suitable tests are carried out to determine residues of reagents used during inactivation and purification. When validation studies have demonstrated removal of residual reagents, the test on conjugate polysaccharides can be omitted.

Appropriate chromatographic procedures (HIC, SEC) and/or filtration (ultrafiltration/diafiltration, tangential-flow filtration) are used to remove the unreacted polysaccharides, protein, residual chemicals, and salts that are used in conjugation or that are by-products of conjugation. Bioburden testing (see *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* <61>) is performed before sterile filtration.

INTERMEDIATES

An intermediate or process intermediate in vaccine manufacture is the reaction product of each step in the process except the last one, which forms the final product. Examples of intermediates are bulk-purified polysaccharides, proteins, and activated polysaccharides that conjugate to protein.

Most vaccine production processes are stepwise and take more than one elementary step to complete. An intermediate is produced from raw materials at one or more process steps (e.g., bacterial growth, extraction and purification, and chemical modification), eventually resulting in the drug substance. The identification of the key intermediates, their production, and sampling for analytical tests must be defined in controlled documents (e.g., batch records, analytical protocols).

Intermediates can be stored for considerable periods of time before further processing and can be included in a formal stability program (see *Storage Stability*, above). Stability studies in normal or accelerated conditions should be performed to define maximal hold time for intermediates and when significant process changes are implemented.

From raw material to finished drug substance, testing throughout the process ensures a quality product. Testing of intermediates is a key quality control step to ensure their identity and purity. The quality attributes of the intermediate are commonly tested in conjunction with further processing, and their release testing should be considered. Standard operating procedures (SOPs) must be properly defined for the analytical control tests. Because of their critical role in the production process, some key intermediates could be included in formal release testing, in addition to the intermediates identified for in-process testing.

Examples of tests for structural characterization of carbohydrate-based intermediates include the following:

- identity and *O*-acetylation level (nuclear magnetic resonance)
- molecular size and polydispersity (SEC–UV, SEC–Refractive Index, SEC–MALLS, SEC–Fluorescence)
- saccharide content [colorimetric assays, high-pH anion-exchange chromatography with pulsed amperometric detection (HPAEC–PAD), -Fluorescence]
- specific rotation, see *Optical Rotation* <781>
- saccharide content, *O*-acetyl content (colorimetric assays)
- counterion content, e.g., Na⁺ and Ca²⁺ (inductively coupled plasma–mass spectroscopy, atomic absorption).

Examples of tests for the purity of carbohydrate-based intermediates based on estimates of the product- and process-related impurities include the following:

- endotoxin content (*Bacterial Endotoxins Test* <85>)
- proteins, nucleic acids, proteins, cetavlon (colorimetric assays)
- water content (Karl Fischer titration; see *Water Determination* <921>)
- volatile substances (thermogravimetry)
- organic solvents, e.g. ethanol, phenol, acetone, DMSO, or ethyl acetate (gas chromatography–flame ionization detection; see *Residual Solvents* <467>)
- bioburden (total viable aerobic count of microbial contamination; see *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* <61>)

Examples of tests for structural characterization and purity estimation of protein-based intermediates include the following:

- identity and molecular size (SDS–PAGE, Western Blot, SEC–UV, SEC–Fluorescence, SEC–MALLS, reverse phase chromatography)
- endotoxin content (see *Bacterial Endotoxins Test* <85>)
- residual nucleic acids [colorimetric assay; see *Nucleic Acid-Based Techniques—Approaches for Detecting Trace Nucleic Acids (Residual DNA Testing)* <1130>]
- bioburden (total viable aerobic count of microbial contamination; see *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* <61>)
- other proteins as impurities (SDS–PAGE, Western Blot, SEC–UV, SEC–Fluorescence, reversed-phase chromatography)

The tests previously reported for protein-based intermediates are also applicable when the protein-based product is defined as the drug substance. In addition to the examples reported above, many other methodologies can be applied for the identity and purity evaluation.

Stability tests for intermediates can include physicochemical methods (see section on *Intermediates*, above), formally included within an analytical panel for the stability study. In addition, biological and immunochemical tests [e.g., enzyme-linked immunosorbent assay (ELISA)] can be included. Bioburden and endotoxin testing may not be required at each level (each intermediate, drug substance) provided testing is performed at sufficient steps in the overall production process. Bioburden is typically performed prior to sterile filtration via in-process testing. If intermediates must be stored and/or subsequently shipped to a different location for further processing, the stability of these materials must be demonstrated.

DRUG SUBSTANCE

The drug substance is the final bulk that contains the antigen at the desired concentration and is ready for the addition of other ingredients (e.g., diluents, bulking agents, stabilizing excipients, adjuvants, or preservatives) to produce the finished dosage formulation.

The drug substance is the final product of the antigen manufacture process, before the formulation of the final vaccine dosage. The final bulk may be prepared aseptically

or may include a sterilization step. Sampling for analytical tests for release and stability studies (see *Storage Stability*, above) must be defined in controlled documents (e.g., batch records, analytical protocols).

Drug substances can be stored for a considerable period of time before further processing, but if it is stored the drug substance must be included in a formal stability program (see *Storage Stability*, above). Stability studies in normal or accelerated conditions should be performed to define maximal hold times. A stability program is required for formal stability studies, and the studies must be executed according to a protocol that contains detailed information about types of tests, specifications, testing intervals, and time points.

Testing of the drug substance must be performed to ensure its identity and purity. All the testing must be done according to established SOPs, and all tests must have specifications (or provisional specifications, where applicable).

Examples of tests for structural characterization of carbohydrate-based products include the following:

- identity and O-acetylation level [nuclear magnetic resonance (NMR)]
- total and free saccharide content [HPAEC-PAD, capillary electrophoresis (CE), or colorimetric assays]
- total and free protein content (colorimetric assay, SEC with UV, RI, or fluorescence detection, CE)
- O-acetyl content (colorimetric assays)
- molecular size (SEC-UV, -RI, -Fluorescence, or -MALLS)

Examples of tests for the purity of carbohydrate-based drug substances based on estimating the product- and process-related impurities include the following:

- endotoxin content (*Bacterial Endotoxins Test* <85>)
- process-related residuals not shown to be removed by process validation (e.g., cyanide, iodate, bromide, ammonium sulfate, or organic solvents)
- Bioburden (total viable aerobic count of microbial contamination; see *Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests* <61>)

In addition to the examples reported above, many other methodologies can be applied for identity and purity evaluation. For instance, specific impurities that must be measured are determined by negotiations between manufacturers and the national drug regulatory agency during the licensure process. Bioburden and endotoxin testing may not be required at each level (each intermediate, drug substance) provided testing is performed at sufficient steps in the overall production process. Bioburden is typically performed prior to sterile filtration via in-process testing.

All the results must be reported in a controlled document. Stability tests can include both physicochemical methods (see stability information, above) and biological/immunochemical tests (e.g. ELISA and SBA; see *Quality of Biotechnological Products: Stability Testing of Biotechnological/Biological Products* <1049>).

DRUG PRODUCT AND LOT RELEASE

General principles are described in *Vaccines for Human Use—General Considerations* <1235>, which outlines the lot release procedure in accordance with 21 CFR 610.1 and 21 CFR 610.2. For products that will be used in the United States, samples and protocols containing all appropriate tests must be submitted to FDA for review and/or testing. If FDA determines that the lot meets the standards of safety, purity, and potency required for the particular vaccine, the lot is approved for release, distribution, and marketing.

Tests required for each lot-release protocol include potency, general safety, sterility, purity, identity, and constituent materials. Potency and potency-related tests are different for each bacterial vaccine. The inclusion of these tests makes each bacterial vaccine lot-release protocol unique.

The contents of a final container of each filling of each lot are tested for identity after labeling is completed. Identity is

established either by physical or chemical characteristics of the vaccine, inspection by macroscopic or microscopic methods, specific cultural tests, or in vivo or in vitro immunological tests. In large part, identity testing is performed to distinguish the vaccine from other materials that are manufactured at the same site (21 CFR 610.14). The same tests that establish identity may also be appropriate for defining the quantity of immunogen present in the final vial. This is especially important for carbohydrate-based vaccines that are dosed by mass and for which physicochemical measures of antigen quality are used.

Immunochemical methods, which include immunoprecipitation methods and immunoelectrophoretic methods, have been useful. Immunoprecipitation methods, flocculation and precipitation, can be carried out in solution or in a gel matrix and involve mixing the antigen with an appropriate antibody, leading to the formation of flocculating or precipitating aggregates that can be detected visually or by light scattering (light scattering or nephelometry). The ratio of reactants must be varied to optimize the detected response. In solution this can be achieved by titrating one reactant with the other, and increased sensitivity can be obtained by using antigen- or antibody-coated particles (e.g., latex) as reactants. In gel systems, a gradient is created as one or more of the reactants diffuse, creating a visible line where precipitation occurs. Immunoelectrophoresis (IE) is a qualitative technique that combines two methods: gel electrophoresis followed by immunodiffusion. Crossed IE is a modification of the IE method that is suitable both for qualitative and quantitative analysis. Visualization and characterization of immunoprecipitation lines can be performed by selective or nonselective stains, fluorescence, enzyme or isotope labeling, or other relevant techniques. Selective staining methods are usually performed for characterization of nonprotein substances in the precipitates. In translucent gels, such as agar or agarose, the precipitation line becomes clearly visible in the gel provided that the concentration of each of the reactants is appropriate.

Where multiple active components are present as a result of copurification (e.g., certain acellular pertussis vaccines), the manufacturer must demonstrate that the composition of the product is consistent between batches, unless this has been validated during the development of the manufacturing process.

For certain vaccines, notably those that use purified polysaccharide immunogens, identity and immunogen quantity can be demonstrated using one or more chemical and physicochemical approaches such as colorimetric determinations of different groups of sugar residues expected to be present, chromatography, or high-field nuclear magnetic resonance spectroscopy.

A number of classical colorimetric assays for quantification of various classes of sugar have been used to define the composition of polysaccharides used as vaccines, including the orcinol assay for ribose, phosphorus, sialic acid, uronic acids, and aminosugars. In general, these approaches have been superseded by chromatographic methods, including gas chromatography and HPAEC, which is widely used to determine Hib PRP glycoconjugate immunogens in monovalent or combination vaccines and in meningococcal conjugate immunogens.

Immunochemical methods that have been used to quantify polysaccharide antigens include (a) rocket immuno-electrophoresis and (b) rate nephelometry. Electroimmunoassay, also called rocket immuno-electrophoresis, is a quantitative method to determine antigens that differ in charge from the antibodies. Electrophoresis of the antigen to be determined is carried out in a gel that contains a lower concentration of the corresponding antibody. Nephelometry methods have been used to quantify antigen in pneumococcal conjugate vaccines.

The consistency of the molecular size and molecular size distribution of polysaccharide- and carbohydrate-containing conjugate vaccines can be determined by gel-permeation chromatography on appropriate resins calibrated with suitable

ble molecular weight markers or coupled to laser light-scattering equipment that indicates absolute molecular weight if a value for the refractive index increment (dn/dc) is known. Measurement of the molecular size of formulated conjugates may not be feasible for multivalent glycoconjugate vaccines. Integrity of the conjugate may be demonstrated by alternative, product-specific methods. Another alternative to demonstrate integrity of the glycoconjugates in the final product is measurement of molecular size as part of the stability studies at monovalent conjugate bulk prior to formulation of the multivalent vaccine.

Unless the contrary has been validated, manufacturers should demonstrate that reversion to toxicity has not occurred (and will not occur over the shelf life) for a product derived from or containing a toxoid material. This may require the use of a cell line or an *in vivo* test, although enzymatic approaches are being validated.

An antigenic purity test is an assay that assesses the quantity of antigen and is used for diphtheria and tetanus toxoid vaccines. The antigen content is determined by a flocculation assay.

The manufacturer should prove a high and consistent level of immunogen adsorption to any solid-phase adjuvant (such as aluminum phosphate or aluminum hydroxide) that is consistent with the release specification.

For certain vaccines such as the anthrax vaccine and toxoid vaccines, the manufacturer is required to demonstrate that the vaccine is protective against disease or death in animal models challenged with a predefined dose of the target pathogen. This generally requires definition of the animal model, route of administration, vaccine dilutions required, a means to observe effects, and a reference vaccine against which effects are compared. The data should be analyzed appropriately (see *Analysis of Biological Assays* <1034>).

Stability-indicating assays are those used to determine the stability of the product. Of primary importance is the potency assay, although glycan degradation may be important in glycoconjugate vaccines.

Other Vaccine Components and Vaccine Properties. Aluminum compounds are the primary adjuvants used in vaccines in the United States. General chapter *Vaccines for Human Use—General Considerations* <1235> provides provisions of the 21 CFR 610.15 governing the use of aluminum and amounts allowed. The adjuvants widely used in bacterial vaccines include aluminum potassium sulfate (alum), aluminum phosphate, aluminum hydroxide, and combinations of these compounds. Bacterial vaccines formulated with such adjuvants are referred to as adsorbed vaccines, and this term may be included in the official name of the vaccine. Other adjuvant systems may be evaluated. Aluminum is quantitated using colorimetric, titrimetric, emission or atomic absorption spectroscopy, or inductively coupled plasma-mass spectrometry.

For regulations regarding residual manufacturing reagents, see the FDA's 1999 *Guidance for Industry: Content and Format of Chemistry, Manufacturing, and Controls Information and Establishment Description Information for a Vaccine or Related Product*. Manufacturing reagents such as formaldehyde and glutaraldehyde sometimes are used in inactivation, the toxoid-making processes, or elsewhere during manufacture and may be present in residual amounts in the final product. Limits of formaldehyde and other residuals must be minimized in accordance with the approved product license.

Common preservatives used in bacterial vaccines include thimerosal, phenol, 2-phenoxyethanol, and benzalkonium chloride. *Vaccines for Human Use—General Considerations* <1235> and 21 CFR 610.15 provide additional information about the minimization of thimerosal content and the production of thimerosal-free vaccines. Limits and content specifications are set for each bacterial vaccine in the product license.

Each lot of final containers of a vaccine intended for use by injection is tested for bacterial endotoxins as indicated in *Bacterial Endotoxins Test* <85>.

Each lot of final containers of a vaccine intended for use by injection may be tested for pyrogenic substances as indicated in *Pyrogen Test* <151> and 21 CFR 610.14.

Each lot of dried product shall be tested for residual moisture (see *Loss on Drying* <731> and FDA Guideline for the Determination of Residual Moisture in Dried Biological Products, January 1990). Residual moisture should be determined for lyophilized vaccines.

A general safety test is performed on biological products intended for administration to humans with the purpose of detecting extraneous toxic contaminants. Procedures and exceptions are specified in 21 CFR 610.11.

Excipient identity and quantity, preservatives, diluents, adjuvants, extraneous protein; and cell culture-produced vaccines and antibiotics are tested according to 21 CFR 610.15 and/or appropriate guidance documents.

"Free" or unconjugated saccharide in glycoconjugate vaccines is considered undesirable and is subject to limit specifications. As an alternative to controlling free or unconjugated saccharide, integrity of the conjugates in the final product may be demonstrated via an appropriate method, said method depending on the properties of the final product (composition, adsorption, etc.). A test method that measures the increase in the amount of free saccharide is a stability-indicating method. The methods adopted depend on separation of saccharide from conjugate and application of the methods above to quantify the unconjugated saccharide. Separation methods used include membrane separation (such as dialysis), use of hydrophobic media to specifically trap the conjugate, solvent extraction, and selective immunochemical precipitation of the conjugate using anticarrier antibodies.

The sterility of each lot of each product is conducted according to procedures described in *Sterility Tests* <71> and 21 CFR 610.12 for both bulk and final container material.

Information insert (Label). Vaccine product labeling is regulated in compliance with 21 CFR 201 and 610. Requirements are set both for container labeling and package labeling.

OTHER REQUIREMENTS

Retention samples are held by the manufacturer for at least six months after the expiration date. Enough material of each lot of each product is held for examination and testing for safety and potency (see 21 CFR 600.13).

Records are maintained concurrently with each step in the manufacture and distribution of product such that at any time successive steps of manufacture and distribution may be traced (see 21 CFR 600.12).

For storage conditions, see 21 CFR 610.50 and 53.

For shelf life/expiry date, see 21 CFR 610.50 and 53.

<1241> WATER–SOLID INTERACTIONS IN PHARMACEUTICAL SYSTEMS

INTRODUCTION

This general chapter is harmonized with the corresponding texts of the *European Pharmacopoeia* and/or the *Japanese Pharmacopoeia*. These pharmacopoeias have undertaken not to make any unilateral change to this harmonized chapter.

Portions of the present general chapter text that are national USP text, and therefore not part of the harmonized text, are marked with symbols (♦) to specify this fact.

Pharmaceutical solids as raw materials or as constituents of dosage forms most often come in contact with water during processing and storage. This may occur (a) during crystallization, lyophilization, wet granulation, or spray drying; and (b) because of exposure upon handling and storage to an atmosphere containing water vapor or exposure to other materials in a dosage form that contain water capable of distributing it to other ingredients. Some properties known to be altered by the association of solids with water include rates of chemical degradation in the “solid-state”, crystal growth and dissolution, dispersibility and wetting, powder flow, lubricity, powder compactibility, compact hardness, and microbial contamination.

Although precautions can be taken when water is perceived to be a problem, i.e., eliminating all moisture, reducing contact with the atmosphere, or controlling the relative humidity of the atmosphere, such precautions generally add expense to the process with no guarantee that during the life of the product further problems associated with moisture will be avoided. It is also important to recognize that there are many situations where a certain level of water in a solid is required for proper performance, e.g., powder compaction. It is essential for both reasons, therefore, that as much as possible is known about the effects of moisture on solids before strategies are developed for their handling, storage, and use.

Some of the more critical pieces of required information concerning water–solid interactions are:

- total amount of water present;
- the extent to which adsorption and absorption occur;
- whether or not hydrates form;
- specific surface area of the solid, as well as such properties as degree of crystallinity, degree of porosity, and glass transition and melting temperature;
- site of water interaction, the extent of binding, and the degree of molecular mobility;
- effects of temperature and relative humidity;
- essentially irreversible hydration;
- kinetics of moisture uptake;
- various factors that might influence the rate at which water vapor can be taken up by a solid;
- for water-soluble solids capable of being dissolved by the sorbed water, under which conditions dissolution will take place.

PHYSICAL STATES OF SORBED WATER

Water can physically interact with solids in different ways. It can interact at the surface (adsorption) or it can penetrate the bulk solid structure (absorption). When both adsorption and absorption occur, the term sorption is often used. Adsorption is particularly critical in affecting the properties of solids when the specific surface area is large. Large values of specific surface area are seen with solids having very small particles, as well as with solids having a high degree of intraparticle porosity. Absorption is characterized by an association of water per gram of solid that is much greater than that which can form a monomolecular layer on the available surface, and an amount that is generally independent of the specific surface area.

Most crystalline solids will not absorb water into their bulk structures because of the close packing and high degree of order of the crystal lattice. Indeed, it has been shown that the degree of absorption into solids exhibiting partial crystallinity and partial amorphous structure is often inversely proportional to the degree of crystallinity. With some crystalline solids, however, crystal hydrates may form. These hydrates may exhibit a stoichiometric relationship, in terms of water molecules bound per solid molecule, or they may be non-stoichiometric. Upon dehydration, crystal hydrates may either retain their original crystal structure, lose their

crystallinity and become amorphous, or transform into a new anhydrous or less-hydrated crystal form.

Amorphous or partially amorphous solids are capable of taking up significant amounts of water because there is sufficient molecular disorder in the solid to permit penetration, swelling, or dissolution. Such behavior is observed with most amorphous polymers and with small-molecular-mass solids rendered amorphous during preparation, e.g., by lyophilization, or after milling. The introduction of defects into highly crystalline solids will also produce this behavior. The greater the chemical affinity of water for the solid, the greater the total amount that can be absorbed. When water is absorbed by amorphous solids, the bulk properties of the solid can be significantly altered. It is well established, for example, that amorphous solids, depending on the temperature, can exist in at least one of two states: “glassy” or “fluid”; the temperature at which one state transforms into the other is the glass transition temperature, T_G .

Water absorbed into the bulk solid structure, by virtue of its effect on the free volume of the solid, can act as an efficient plasticizer and reduce the value of T_G . Because the rheological properties of “fluid” and “glassy” states are quite different, i.e., the “fluid” state exhibits much less viscosity as the temperature rises above the glass transition point, it is not surprising that a number of important bulk properties dependent on the rheology of the solid are affected by moisture content. Because amorphous solids are metastable relative to the crystalline form of the material, with small-molecular-mass materials, it is possible for absorbed moisture to initiate reversion of the solid to the crystalline form, particularly if the solid is transformed by the sorbed water to a “fluid” state. This is the basis of “cake collapse” often observed during the lyophilization process. An additional phenomenon noted specifically with water-soluble solids is their tendency to deliquesce, i.e., to dissolve in their own sorbed water, at relative humidities, RH_i , in excess of the relative humidity of a saturated solution of the solid, RH_0 . Deliquescence arises because of the high water solubility of the solid and the significant effect it has on the colligative properties of water. It is a dynamic process that continues to occur as long as RH_i is greater than RH_0 .

The key to understanding the effects water can have on the properties of solids, and vice versa, rests with an understanding of the location of the water molecule and its physical state. More specifically, water associated with solids can exist in a state that is directly bound to the solid, as well as in a state of mobility approaching that of bulk water. This difference in mobility has been observed through such measurements as heat of sorption, freezing point, nuclear magnetic resonance, dielectric properties, and diffusion.

Such changes in mobility have been interpreted as arising because of changes in the thermodynamic state of water as more and more water is sorbed. Thus, water bound directly to a solid is often thought as unavailable to affect the properties of the solid, whereas larger amounts of sorbed water may become more clustered and form water more like that exhibiting solvent properties. In the case of crystal hydrates, the combination of intermolecular forces (hydrogen bonding) and crystal packing can produce very strong water–solid interactions. Recognizing that the presence of water in an amorphous solid can affect the glass transition temperature and hence the physical state of the solid, at low levels of water, most polar amorphous solids are in a highly viscous glassy state because of their high values of T_G . Hence, water is “frozen” into the solid structure and is rendered immobile by the high viscosity, e.g., 10^{13} Pa · s. As the amount of water sorbed increases and T_G decreases, approaching ambient temperatures, the glassy state approaches that of a “fluid” state and water mobility along with the mobility of the solid itself increases significantly. At high RH , the degree of water plasticization of the solid can be sufficiently high so that water and the solid can now achieve significant amounts of mobility. In general, therefore, this picture of the nature of sorbed water helps to explain the rather significant effect moisture can have on a

number of bulk properties of solids such as chemical reactivity and mechanical deformation. It suggests strongly that methods of evaluating chemical and physical stability of solids and solid dosage forms take into account the effects water can have on the solid when it is sorbed, particularly when it enters the solid structure and acts as a plasticizer.

Rates of Water Uptake

The rate and extent to which solids exposed to the atmosphere might either sorb or desorb water vapor can be a critical factor in the handling of solids. Even the simple act of weighing out samples of solid on an analytical balance and the exposure, therefore, of a thin layer of powder to the atmosphere for a few minutes can lead to significant error in, for example, the estimation of loss on drying values. It is well established that water-soluble solids exposed to relative humidities above that exhibited by a saturated solution of that solid will spontaneously dissolve via deliquescence and continue to dissolve over a long time period. The rate of water uptake in general depends on a number of parameters not found to be critical in equilibrium measurements because rates of sorption are primarily mass-transfer controlled with some contributions from heat-transfer mechanisms. Thus, factors such as vapor diffusion coefficients in air and in the solid, convective airflow, and the surface area and geometry of the solid bed and surrounding environment, can play an important role. Indeed, the method used to make measurements can often be the rate-determining factor because of these environmental and geometric factors.

DETERMINATION OF SORPTION–DESORPTION ISOTHERMS

Principle

The tendency to take up water vapor is best assessed by measuring sorption or desorption as a function of relative humidity, at constant temperature, and under conditions where sorption or desorption is essentially occurring independently of time, i.e., equilibrium. Relative humidity, RH, is defined by the following equation:

$$RH = (P_c \times 100)/P_0$$

P_c = pressure of water vapor in the system

P_0 = saturation pressure of water vapor under the same conditions

The ratio P_c/P_0 is referred to as the relative pressure. Sorption or water uptake is best assessed starting with dried samples and subjecting them to a known relative humidity. Desorption is studied by beginning with a system already containing sorbed water and reducing the relative humidity. As the name indicates, the sorption–desorption isotherm is valid only for the reference temperature, hence a special isotherm exists for each temperature. Ordinarily, at equilibrium, moisture content at a particular relative humidity must be the same, whether determined from sorption or desorption measurements. However, it is common to see sorption–desorption hysteresis.

Methods

Samples may be stored in chambers at various relative humidities. The mass gained or lost for each sample is then measured. The major advantage of this method is convenience, while the major disadvantages are the slow rate of reaching constant mass, particularly at high relative humidities, and the error introduced in opening and closing the

chamber for weighing. Dynamic gravimetric water sorption systems allow the on-line weighing of a sample in a controlled system to assess the interaction of the material with moisture at various programmable levels of relative humidity at a constant temperature. The major benefit of a controlled system is that isothermal conditions can be more reliably established and that the dynamic response of the sample to changing conditions can be monitored (see Figure 1). Data points for the determination of the sorption isotherm (e.g., from 0% to approximately 95% RH, noncondensing) are only taken after a sufficiently constant signal indicates that the sample has reached equilibrium at a given level of humidity. In some cases (e.g., deliquescence), the maximum time may be restricted although the equilibrium level is not reached. The apparatus must adequately control the temperature to ensure a good baseline stability as well as accurate control of the relative humidity generation. The required relative humidities can be generated, e.g., by accurately mixing dry and saturated vapor gas with flow controllers. The electrostatic behavior of the powder must also be considered. The verification of the temperature and the relative humidity (controlled with, for example, a certified hygrometer, certified salt solutions, or deliquescence points of certified salts over an adequate range) must be consistent with the instrument specification. The balance must provide a sufficient mass resolution and long-term stability.

It is also possible to measure amounts of water uptake not detectable gravimetrically using volumetric techniques. In the case of adsorption, to improve sensitivity, the specific surface area of the sample can be increased by reducing particle size or by using larger samples to increase the total area. It is important, however, that such comminution of the solid does not alter the surface structure of the solid or render it more amorphous or otherwise less ordered in crystallinity. For absorption, where water uptake is independent of specific surface area, only increasing sample size will help. Increasing sample size, however, will increase the time to establish some type of equilibrium. To establish accurate values, it is important to get desolvation of the sample as thoroughly as possible. Higher temperatures and lower pressures (vacuum) facilitate this process; however, care must be taken to note any adverse effects this might have on the solid such as dehydration, chemical degradation, or sublimation. Using higher temperatures to induce desorption, as in a thermogravimetric apparatus, likewise must be carefully carried out because of these possible pitfalls.

Report and Interpretation of the Data

Sorption data are usually reported as a graph of the apparent mass change in percent of the mass of the dry sample as a function of relative humidity or time. Sorption isotherms are reported both in tabular form and as a graph. The measurement method must be traceable with the data.

Adsorption–desorption hysteresis can be interpreted, for example, in terms of the porosity of the sample, its state of agglomeration (capillary condensation), the formation of hydrates, polymorphic change, or liquefying of the sample. Certain types of systems, particularly those with microporous solids and amorphous solids, are capable of sorbing large amounts of water vapor. Here, the amount of water associated with the solid as relative humidity is decreased, is greater than the amount that originally sorbed as the relative humidity was increased. For microporous solids, vapor adsorption–desorption hysteresis is an equilibrium phenomenon associated with the process of capillary condensation. This takes place because of the high degree of irregular curvature of the micropores and the fact that they “fill” (adsorption) and “empty” (desorption) under different equilibrium conditions. For nonporous solids capable of absorbing water, hysteresis occurs because of a change in the degree of vapor–solid interaction due to a change in the equilibrium state of the solid, e.g., conformation of polymer

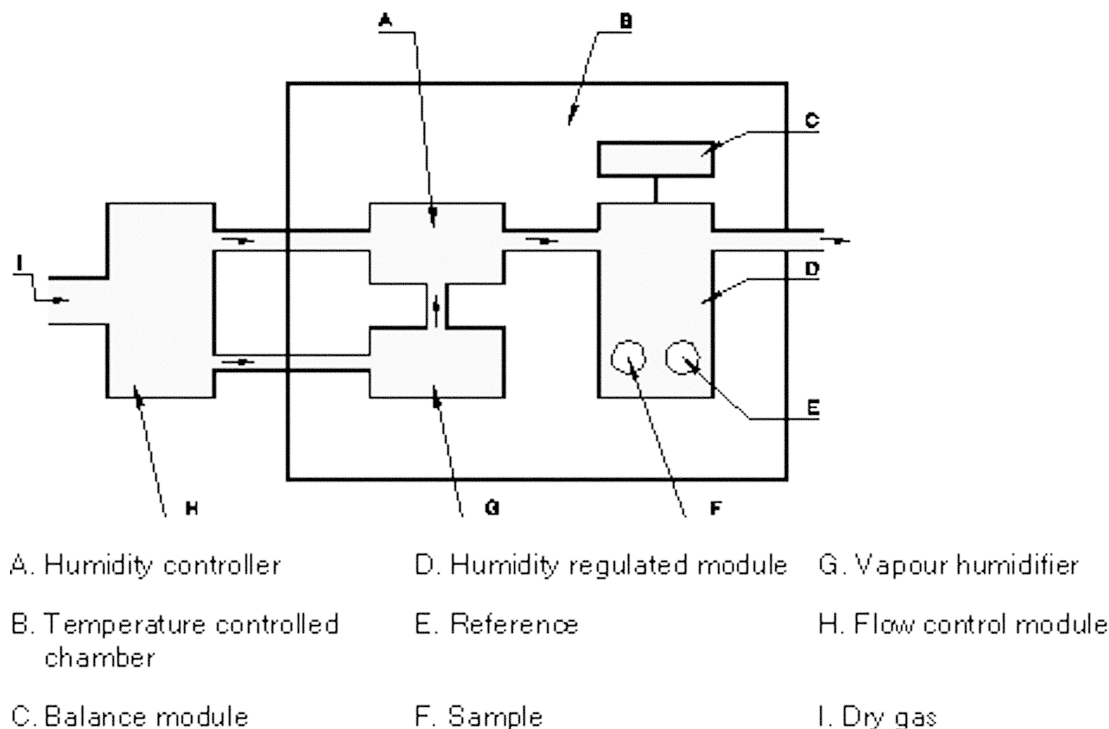

Figure 1. Example of an apparatus for the determination of the water sorption (other designs are possible).

chains, or because the time scale for structural equilibrium is longer than the time scale for water desorption. In measuring sorption–desorption isotherms, it is therefore important to establish that something close to an equilibrium state has been reached. Particularly with hydrophilic polymers at high relative humidities, the establishment of water sorption or desorption values independent of time is quite difficult, because one is usually dealing with a polymer plasticized into its “fluid” state, where the solid is undergoing significant change.

In the case of crystal hydrate formation, the plot of water uptake versus pressure or relative humidity will in these cases exhibit a sharp increase in uptake at a particular pressure and the amount of water taken up will usually exhibit a stoichiometric mole:mole ratio of water to solid. In some cases, however, crystal hydrates will not appear to undergo a phase change or the anhydrous form will appear amorphous. Consequently, water sorption or desorption may appear more like that seen with adsorption processes. X-ray crystallographic analysis and thermal analysis are particularly useful for the study of such systems.

For situations where water vapor adsorption occurs predominantly, it is very helpful to measure the specific surface area of the solid by an independent method and to express adsorption as mass of water sorbed per unit area of solid surface. This can be very useful in assessing the possible importance of water sorption in affecting solid properties. For example, 0.5% m/m uptake of water could hardly cover the bare surface of 100 m²/g, while for 1.0 m²/g this amounts to 100 times more surface coverage. In the case of pharmaceutical solids that have a specific surface area in the range of 0.01 m²/g to 10 m²/g, what appears to be low water content could represent a significant amount of water for the available surface. Because the “dry surface area” is not a factor in absorption, sorption of water with amorphous or partially amorphous solids can be expressed on the basis of unit mass corrected for crystallinity, when the crystal form does not sorb significant amounts of water relative to the amorphous regions.

DETERMINATION OF THE WATER ACTIVITY

Principle

Water activity, A_w , is the ratio of vapor pressure of water in the product (P) to saturation pressure of water vapor (P_0) at the same temperature. It is numerically equal to 1/100 of the relative humidity (RH) generated by the product in a closed system. RH can be calculated from direct measurements of partial vapor pressure or dew point, or from indirect measurement by sensors whose physical or electric characteristics are altered by the RH to which they are exposed. Ignoring activity coefficients, the relationship between A_w and equilibrium relative humidity (ERH) are represented by the following equations:

$$A_w = P/P_0$$

$$\text{ERH}(\%) = A_w \times 100$$

Method

The water activity is determined by placing the sample in a small airtight cup inside which the equilibrium between the water in the solid and the headspace can be established. The volume of the headspace must be small in relation to the sample volume in order not to change the sorption state of the sample during the test. The equilibration as a thermodynamic process takes time but may be accelerated by forced circulation within the cell. The acquired water activity value is only valid for the simultaneously determined temperature. This requires a precise temperature-measuring device as part of the equipment. Furthermore, the probe must be thermally insulated to guarantee a constant temperature during the test. The sensor measuring the humidity of the headspace air above the sample is a key component.

Theoretically, all types of hygrometers can be used, but for analytical purposes miniaturization and robustness are a precondition. The A_w measurement may be conducted using the dew point/chilled mirror method.¹ A polished, chilled mirror is used as a condensing surface. The cooling system is electronically linked to a photoelectric cell into which light is reflected from the condensing mirror. An air stream, in equilibrium with the test sample, is directed at the mirror which cools until condensation occurs on the mirror. The temperature at which this condensation begins is the dew point from which the ERH is determined. Commercially available instruments using the dew point/chilled mirror method or other technologies need to be evaluated for suitability, validated, and calibrated when used to make water activity determinations.

These instruments are typically calibrated over an adequate range, for example, using some saturated salt solutions at 25° such as those listed in Table 1.

Table 1. Standard Saturated Salt Solutions

Saturated Salt Solutions at 25°	ERH (%)	A_w
Potassium sulfate (K_2SO_4)	97.3	0.973
Barium chloride ($BaCl_2$)	90.2	0.902
Sodium chloride (NaCl)	75.3	0.753
Magnesium nitrate ($Mg(NO_3)_2$)	52.9	0.529
Magnesium chloride ($MgCl_2$)	32.8	0.328
Lithium chloride ($LiCl_2$)	11.2	0.112

<1251> WEIGHING ON AN ANALYTICAL BALANCE

Weighing is a frequent step in analytical procedures, and the balance is an essential piece of laboratory equipment in most analyses. In spite of this, weighing is a common source of error that can be difficult to detect in the final analytical results. The procedure described here applies directly to electronic balances; therefore, certain portions of the procedure are not applicable to other types of balance. The weighing procedure can be separated into three basic steps: planning, checking the balance, and weighing the material.

PLANNING

The initial step is to assemble the proper equipment, such as containers for weighing, receiving vessels, forceps, pipets, spatulas of proper size, and so forth. Use containers of size such that the loading capacity of the balance is not exceeded. Make sure that the containers selected to receive the weighed material are clean and dry. Assemble the necessary chemicals if solutions or reagents are required.

Preparation of the material to be weighed is often necessary. The material may require grinding or drying. Some materials may have been heated or stored in a refrigerator. Materials must be brought to the temperature of the balance before they are weighed. To avoid condensation of moisture, refrigerated materials must be allowed to come to room temperature before the container is opened.

¹ AOAC International Official Method 978.18.

CHECKING THE BALANCE

In the next step it is important to remember that, unless the balance is checked before each weighing operation is performed, errors can easily occur, resulting in faulty analytical data. The balance user should check the *Balance Environment*, *Calibration*, and *Balance Uncertainties*. Do not assume that the balance has been left in the proper operating condition by the previous user.

Balance Environment

The balance is placed in a suitable location with sufficiently low levels of vibration and air current. It must have a constant electrical supply. The balance and the surrounding work area have to be kept neat and tidy. It is good practice to use a camel's hair brush or its equivalent to dust the balance pan before any weighing so as to remove any materials that may have been left by the previous operator. [NOTE—Individuals must clean up debris, dispose of any spilled materials or paper, and remove the vessels and apparatus used in making the measurements.] When a balance is moved, it must be allowed to adjust to the temperature of its new environment and be recalibrated.

Calibration

If necessary, turn on the power, and allow the balance to equilibrate for at least 1 hour before proceeding with the calibration. (Microbalances may require up to 24 hours to reach equilibrium.) If the balance power has gone off and then has come back on, as in a power outage, certain types of balance may display a message indicating that the balance must be calibrated before a weighing is made. If the operator touches the balance bar, the message may be cleared and the balance may display zeros; however, the balance will not give the correct weighing until it has been calibrated. Electronic analytical balances have an internal calibration system based on an applied load. The calibration applies for the current ambient temperature.

Balance Uncertainties

DRIFT REDUCTION

Drift is one of the most common errors, and it is also one of the easiest to reduce or eliminate. Balance drift can be present without the operators being aware of the problem. Check the sample, the balance, and the laboratory environment for the following causes of errors, and eliminate them:

1. A balance door is open.
2. Temperatures of the balance and the material to be weighed are not the same.
3. The sample is losing or gaining weight.
4. The balance has been recently moved but has not been allowed to equilibrate to its surroundings or has not been recalibrated.
5. Air currents are present in the laboratory.
6. Temperatures in the laboratory vary.
7. The balance is not properly leveled.
8. Laboratory operations are causing vibration.
9. Hysteresis of the mechanical parts occurs during weighing.

MECHANICAL HYSTERESIS

Hysteresis in the balance is caused by excessive stretching of the springs, and it is primarily due to overloading or to the accidental dropping of an object onto the pan. Microbalances are very sensitive to overload and shock.

When using a microbalance, set the lever to the rest position when adding or removing material; turn the lever to the weigh position to register the weight. In some cases, drift due to hysteresis can be eliminated by allowing the balance to stand without weighing long enough for it to recover. If stretching of the springs is excessive, an expensive balance overhaul may be needed. In the case of electronic force restoration balances, springs are replaced by flexures, and the term *creep* is more appropriate than *hysteresis*.

QUALITY ASSURANCE PROCEDURE FOR MEASUREMENT OF BALANCE DRIFT

Over an extended period of time, balance drift and other day-to-day variations are monitored by weighing a fixed check-weight on a regular basis; this check should be performed after the balance has been calibrated at the ambient laboratory temperature. The check should be made before the first weighing of the day or after any event that might disturb the balance's calibration (power failure, moving the balance to a new location, etc.). The check-weight may be any object whose mass remains constant and does not exceed the load limit of the balance. A balance weight makes a reliable check-weight. Each balance should be provided with a check-weight, which should be stored in a protective container near the balance.

Perform the following procedures to reduce balance errors and the possibility of an incorrect reading because of drift:

1. Make certain that the electrical power to the balance is on and that the level bubble is in the center of the indicator.
2. Calibrate the analytical balance or the microbalance. [NOTE—Some balances have a calibration lever, which must be returned fully to its original weighing position. Do not depend upon any prior calibration.]
3. The first person to use the balance each day should weigh the check-weight and record the weight in the log book for comparison with previous readings. If a deviation greater than those indicated below for *Analytical Balances* and *Microbalances* is observed, the balance should be reported for service. [NOTE—Check-weights tend to gain weight upon standing because of mishandling and exposure to contaminants in the atmosphere. These weights can be cleaned by wiping with a lint-free cloth moistened with a small amount of an appropriate solvent such as diethyl ether.]

Analytical Balances—Select a check-weight of an appropriate mass to examine an analytical balance. If possible, set the balance to read to 5 decimal places. Follow the manufacturer's operating instructions. Pick up the check-weight with a forceps, place it carefully on the balance pan, and weigh it. [NOTE—Do not drop the weight on the balance pan, because damage to the balance could result.] Place the weight in the center of the pan to eliminate corner-weighing differences. The accuracy of the weight is not important; the only factor of interest is whether any drift has occurred. If no drift has taken place, the value should remain constant. Periodic weighing of a fixed weight will determine whether the boards (or knife edges in mechanical balances) in the instrument are defective. The check for drift at the most sensitive position will show whether a problem exists; the variation in the observed weight does not exceed ± 0.2 mg. For example, with a 20-g weight, if the mean value of the readings were 19.9984, the tolerance would be from 19.9982 to 19.9986 g. Thus, several readings must be taken before one can establish a tolerance. [NOTE—The check-weight need not be of high accuracy, but it is essential that its mass remain constant. In addition, the tolerance does not correspond to the value of 0.1%, specified under *Weights and Balances* (41), for weighing material accurately.

Rather, the tolerance is purposefully tight to reveal possible drift or calibration errors; this tolerance is readily achievable with modern electronic balances.]

Microbalances—Proceed as directed for *Analytical Balances*, but use a check-weight appropriate for the particular balance. For example, a 100-mg check-weight might be selected for a balance that has a load limit of 150 mg; or a 10-mg check-weight might be used for an ultramicrobalance with a load limit of 15 mg. (The operator must know the maximum capacity of the balance to select the correct check-weight.) The balance indicates the weight in milligrams. Record the weight as soon as the reading is stable for a few seconds. The variation in weighings ought to be within a range commensurate with the specifications given by the balance manufacturer, but not greater than 0.1% of the amount of material typically weighed on the particular balance. For example, if 10-mg samples are routinely weighed, the variation in the weighings of the check-weight cannot exceed 0.01 mg.

WEIGHING THE MATERIAL

In this final step, select the number of decimal places required for the analytical procedure. In most pharmaceutical analyses small quantities of material are used, requiring the balance reading to be set to the fifth decimal place to achieve the necessary accuracy. Weighing read with four decimal places is preferred for weighing near-gram quantities. Do not allow the material to remain on the balance for an extended period of time because changes, caused by interaction with atmospheric water or carbon dioxide, may take place.

Load Limit

Select the appropriate balance for the quantity and accuracy needed. Each balance has a load limit, which should not be exceeded. Each balance manufacturer supplies the maximum loading condition, and this limit varies with the type of balance. The operator should know this limit so that the balance will not be damaged. [NOTE—Electronic balances operate on a "load cell" principle that produces an electrical output proportional to the movement of the strain gauge and is linear over the range.]

Receivers

The proper receiver for the material must be selected. The receiver's weight plus the weight to be measured must not exceed the maximum load for the balance; the size and shape of the receiver should permit it to fit into the space and on the balance pan without interfering with any operation. It is important that the receiver be clean and dry. Common receivers are weighing bottles, weighing funnels, flasks, and weighing paper. The correct receiver depends upon the quantity and type of material (liquid, solid, or powder) to be weighed. All other things being equal, a vessel of low mass should be chosen when small amounts of material are to be weighed. It is recommended that gloves, forceps, or another type of gripping device be used when handling receivers, because oils from the hands will add weight.

The weighing funnel is often the most satisfactory receiver, because it can function as both a weighing dish and a transfer funnel, allowing easy transfer to volumetric flasks. Weighing funnels come in various sizes; the size suitable for the operation should be selected.

Weighing paper may be used for solids. Paper receivers must be handled by hand, and great care must be used to prevent spills.

Weighing by Difference

Weighing is usually done by difference. The following methods are acceptable for good analytical results.

METHOD 1

Tare the empty receiver as follows. Place the receiver on the balance in the center of the pan, and press the appropriate tare key on the balance. This operation electrically sets the signal from the strain gauge to zero so that the weight of the receiver is no longer indicated. Add the material to the receiver, and record the weight. Transfer the weighed material to the final flask or receiver; then reweigh the original weighing receiver by placing it in the same position on the pan. [NOTE—Do not change the set tare of the balance between these two weighings.] The second weight represents the untransferred material and is subtracted from the total material weight to determine the weight of the transferred material.

METHOD 2

If the empty receiver is not going to be tared, add the material to the receiver, and place the receiver on the balance in the center of the pan. Record the weight, and transfer the weighed material to the final flask or receiver; then reweigh the original weighing receiver by returning it to the same position on the pan. The second weight represents the sum of the weights of the receiver and the untransferred material; subtract this sum from the sum of the total material weight and the receiver weight to determine the weight of the transferred material.

METHOD 3

This method may be described as quantitative transfer. The material is added to the tared receiver, the amount is determined by difference, and then the whole amount is transferred quantitatively (e.g., by using a solvent) to the final receiver.

Materials-Handling Safety Procedures

The operator must be familiar with precautions described in the Material Safety Data Sheet for the substance before weighing it. Hazardous materials must be handled in an enclosure having appropriate air filtration. Many substances are extremely toxic, are possibly allergenic, and may be liquids or finely divided particles. A mask that covers the nose and mouth should be used to prevent any inhalation of chemical dust. Gloves should be used to prevent any contact with the skin. [NOTE—The use of gloves is good practice for handling any chemical. If it is necessary to handle the container being weighed, the operator should put on gloves, not only for self-protection but also to prevent moisture and oils from being deposited on the weighed container.] During a weighing, the operator may be exposed to high concentrations of the pure substance; therefore, the operator must carefully consider these possibilities at all times.

Weighings are made on many different types of materials, such as large solids, finely divided powders, and liquids (viscous or nonviscous, volatile or nonvolatile). Each type of material requires its own special handling.

Weighing Solids

Solids come in two forms: large chunks, with or without powdery surface, and finely divided powders or small crys-

tals. If large chunks with a powdery surface are to be weighed, at least a piece of weighing paper must be placed on the balance pan to protect it from damage. Large nonreactive chunks that have no powdery surface may be placed directly on the pan (for example, a coated tablet). [NOTE—Solid pieces must be handled with forceps, never by hand.]

STATIC CHARGE

Fine powders have a tendency to pick up static charge, which will cause the particles to fly around. This static charge must be eliminated before a suitable weighing can be made. An antistatic device may be used to minimize this problem. [NOTE—Such devices may use piezoelectric components or a very small amount of a radioactive element (typically polonium) to generate a stream of ions that dissipate the static charge when passed over the powder to be weighed.] The static charge depends upon the relative humidity of the laboratory, which in turn depends upon the atmospheric conditions. In certain conditions, static charge is caused by the type of clothing worn by the operator; this charge causes large errors in the weighing when discharged.

WEIGHING PROCEDURE

Place the receiver on the balance pan, close the balance door, and weigh as indicated for *Weighing by Difference*, with the following additions. Carefully add the powdered material from a spatula until the desired amount is added. Use care to avoid spilling. Close the balance door, and record the weight as soon as the balance shows a stable reading.

SPILLS

If solids are spilled, remove the receiver, and sweep out all of the spilled material from the balance. The spilled material must be properly disposed of and must not be swept out onto the balance table where other operators may come in contact with the chemical. Then either start the process over or reweigh the remaining material. [NOTE—Never return any excess material to the original container. Any excess material must be disposed of in a proper manner.]

Weighing Liquids

Liquids may be volatile or nonvolatile and viscous or nonviscous. Each type requires special attention.

WEIGHING PROCEDURE

Weigh as directed for *Weighing by Difference*, with the following additions. Liquids should always be weighed into a container that can be closed so that none of the material is lost. It is best if the liquid can be added to its receiving container outside the balance because of the possibility of a spill. [NOTE—Liquids spilled within the balance housing can cause serious damage to the balance, and they may be difficult to remove.]

Nonviscous liquids can be handled with a Pasteur capillary pipet equipped with a small rubber bulb such as a medicine dropper bulb. The liquid is discharged into its receiver, the top is closed or stoppered, and the receiver and contents are weighed. Small quantities of viscous liquids can be handled by touching a glass stirring rod to the surface of the liquid and then carefully touching the rod to the side of the receiving vessel, which allows some of the material to be transferred.

Weighing Corrosive Materials

Many chemicals, such as salts, are corrosive, and materials of this nature should not be spilled on the balance pan or inside the balance housing. Extreme care is essential when materials of this nature are being weighed.

CONCLUSION

By carefully following the procedures outlined above, laboratory personnel will eliminate many errors that might be introduced into weighing procedures. However, it is important for each balance to be serviced and calibrated regularly by a specially trained internal or external service person. The balance should be tested using weights traceable to standardization by the National Institute of Standards and Technology. No repairs should be made to any balance by anyone other than a qualified maintenance person.

(1265) WRITTEN PRESCRIPTION DRUG INFORMATION— GUIDELINES

The purpose of these guidelines—comprising format, content, and accessibility of prescription drug leaflets—is to help ensure that leaflets are useful. In this context, “useful” means that recipients receive, understand, and are motivated to apply written information about their medicines to achieve maximum benefit and minimize harm. Dispensers, prescribers, health care providers who counsel patients about their medicines, and the patients themselves are intended to be the primary beneficiaries for these guidelines.

CRITERIA (from the Keystone Action Plan¹)

Written prescription medicine information should be based on the following criteria:

1. Scientifically accurate,
2. Unbiased in content and tone,
3. Sufficiently specific and comprehensive,
4. Presented in an understandable and legible format that is readily comprehensible to consumers,
5. Timely and up-to-date, and
6. Useful.

FORMAT GUIDELINES

1. Group all information from the same category, using brief, clear titles and bullets or subheadings as needed. Avoid symbols and subheadings not directly connected to the information they mark.
2. Be consistent in the placement and labeling of categories of information in all leaflets.
3. Provide information at the sixth-grade reading level or below, if possible (never above eighth-grade level).

¹ In December 1996, the “Action Plan for the Provision of Useful Prescription Medicine Information” was presented to the Secretary of Health and Human Services. The plan, commonly known as the “Keystone Plan,” described certain criteria for written prescription medicine information. These criteria are described in detail in the action plan, which can be found at www.fda.gov/cder/offices/ods/keystone.pdf.

Do not exclude information to achieve a lower reading level.

4. Use simple, common, accurate terms (for example, use “noise in the ears”, not “tinnitus”).
5. Use direct language that avoids words with opposite meanings (for example, use “decrease blood pressure”, not “increase low blood pressure effect”).
6. Provide reasons for instructions (for example, “take with food to avoid upset stomach”).
7. Emphasize the most important information. Clearly distinguish warnings from instructions or from other text that may be misinterpreted as warnings.
8. Accompany each pictogram, if used, with corresponding text placed close to the pictogram. Use the simplest pictograms possible. For pictograms intended to prompt patients to ask questions or inform health care providers, add text such as “Tell Doctor” or “Ask Pharmacist”.
9. Make text readable by using 12-point or larger type, both uppercase and lowercase letters, an easy-to-read font (for example, a serif font), and adequate space between lines and paragraphs. To call attention to important information, use a larger, boldface type.
10. Evaluate format by performing tests of readability, comprehension, memory, problem solving, and behavioral efficacy and intention, using representative samples of the target population.

CONTENT GUIDELINES

1. Provide enough detail to facilitate correct use, achieve maximum benefit, and minimize harm, including a statement that identifies activities (such as driving or sunbathing) that the patient should avoid.
2. Write text that is unbiased in content and tone and scientifically accurate. The uses described should be consistent with FDA-approved labeling or otherwise permitted by FDA, or should appear in federally recognized drug compendia. Distinguish unlabeled from labeled use.
3. For drugs sold under a brand name, provide both brand and generic names, and include a pronunciation guide for each.
4. Describe the drug and its dosage form. Include indications and contraindications, specific directions for use, what to do if a dose is missed, and what to do in the event of an overdose or poisoning.
5. Do not use abbreviations.
6. Indicate the intended type of benefit (for example, “cure”, “prevention”, “to help relieve symptoms”). Indicate how—and how soon—the patient should recognize the benefit and what to do if none is observed.
7. Give a balanced evaluation of risks and benefits.
8. List side effects, in order of severity, such as “serious”, “most common”, and other similar type groupings. It may not be appropriate to provide sufficient detail for the patient to be able to monitor serious or common side effects. Provide guidance to consult the doctor or pharmacist, and indicate that not all the side effects are listed.
9. List sufficiently specific and comprehensive information that includes the provision of all important risk information. Patients should be advised to be sure to inform the provider about all the medicines they are taking.
10. Indicate the potential for therapeutic duplication if the drug is available under multiple names or over-the-counter, or if the active ingredient is contained in other products.
11. If known, include a statement concerning the safety of use in the presence of other conditions and during pregnancy or breast-feeding. Direct affected patients to discuss their condition with health care providers.

If the safety of use during pregnancy or breast-feeding has not been established, say so.

12. State whether safety and efficacy have been established in pediatric, geriatric, and other special populations. Patients should be encouraged to discuss with their health care provider any recommendations for dosage adjustment.
13. Illustrate information with diagrams when appropriate. Label the diagram components (for example, device parts) if they are not obvious. The words on the label should be prominently placed thereon with such conspicuousness and in such terms as to render them likely to be read and understood by the ordinary individual under customary conditions of purchase and use.
14. Include the following:
 - a. A statement that the product is to be used only by the person for whom it was prescribed,
 - b. Storage information,
 - c. A completeness disclaimer advising the patient to discuss this issue with the health care provider,
 - d. The publisher of the leaflet and the date the leaflet was developed or revised,
 - e. Sources of in-depth information and answers to questions, and
 - f. Other relevant general statements.
15. The patient should be advised about risks of developing dependence on, or tolerance to, the medication.

ACCESSIBILITY GUIDELINES

1. Write text that is relevant to the intended use of the drug.
2. Design the leaflets to be easy to recognize, consistent in format, and easy to store and retrieve.
3. Supplement the leaflets with oral counseling of patients, including children, the elderly, and caregivers.
4. Include a statement asking the patient to reread the leaflet.
5. Distribute the leaflets with all prescription medicines to consumers (namely, persons independently responsible for any aspect of medicine use or for giving medicines to others).
6. Produce leaflets in Spanish, English, or other languages; and establish criteria for producing them in other languages and for special populations (for example, children, visually handicapped) [NOTE—Ideally, prescription drug information leaflets would be customized for the patient's condition and for other relevant information (for example, gender, age, or physical limitations), and would be available in the patient's primary language. Currently, such customization is neither feasible nor practical, but it remains a goal.]

(1601) PRODUCTS FOR NEBULIZATION—CHARACTERIZATION TESTS

Products used for nebulization and intended for pulmonary delivery are characterized using the following tests:

- *Drug Substance Delivery Rate and Total Drug Substance Delivered;*

— *Aerodynamic Assessment of Nebulized Aerosols.*

These tests standardize the approach to the assessment of the dose that would be delivered to a patient but are not intended to provide assessment of the nebulizer device itself.¹ The mass rather than the number-weighted size distribution is more appropriate to evaluate product performance. Drug substance mass as a function of aerodynamic diameter is more indicative of therapeutic effect within the respiratory tract.

DRUG SUBSTANCE DELIVERY RATE AND TOTAL DRUG SUBSTANCE DELIVERED

These tests are performed to assess the rate of delivery to the patient and the total drug substance delivered to a patient using standardized conditions of volumetric flow rate. Breath-enhanced and breath-actuated nebulizers should be evaluated by a breathing simulator because the output of these types of device is highly dependent on inhalation flow rate. The methodology below describes the use of a standard breathing pattern defined for adults. Should a particular product for nebulization be indicated only for pediatric, i.e., neonate, infant, or child use, then pediatric breathing pattern(s) must be used.² Breathing patterns are used, rather than continuous flow rates, to provide a more appropriate measure of the mass of drug substance that would be delivered to patients.

Drug substance delivery rate and total drug substance delivered are appropriate characteristics because they allow the mass delivered to be characterized in a standard way regardless of the nebulizer used. Accordingly, the test methodology described below (a) measures the mass of drug substance delivered in the first period (typically 1 min) consequently giving an assessment of drug substance delivery rate and (b) captures the total drug substance mass delivered.

Apparatus

Breathing Simulator—A commercially available breathing simulator that is able to generate the breathing profiles specified in *Table 1* is used for the test. The breathing profile indicated for adults is used unless the medicinal product is specifically intended for use in pediatrics, when alternate patterns should be used, as indicated in *Table 1*.

Filter System—A suitably validated low-resistance filter, capable of quantitatively collecting the aerosol and enabling recovery of the drug substance with an appropriate solvent, is used for the test. The dead volume of the filter casing does not exceed 10% of the tidal volume used in the breath simulation.

Procedure

Attach the filter (contained in the filter holder) (A) to the breath simulator (B) according to *Figure 1*. Fill the nebulizer (C) with the volume of the drug product as specified in the patient instructions. Attach the mouthpiece of the nebulizer to the inhalation filter using a mouthpiece adapter if required, ensuring that connections are airtight. Position the nebulizer in the same orientation as intended for use. This

¹ European Standard 13544-1:2001. *Respiratory Therapy Equipment*. Part 1: Nebulizing systems and their components. European Committee for Standardization. Brussels, Belgium. 2001.

² Suitable breathing patterns for pediatric use may be found, for example, in Canadian Standard CAN/CSA/Z264.1-02:2002, *Spacers and Holding Chambers for Use with Metered Dose Inhalers*. Canadian Standards Association, Mississauga, Canada 2002.

Table 1. Breathing Simulator Specification

Item	Specification			
	Adult	Neonate	Infant	Child
Total volume	500 mL	25 mL	50 mL	155 mL
Frequency	15 cycles/min	40 cycles/min	30 cycles/min	25 cycles/min
Waveform	sinusoidal	sinusoidal	sinusoidal	sinusoidal
Inhalation:exhalation ratio	1:1	1:3	1:3	1:2

A. inhalation filter and filter holder B. breathing simulator C. nebulizer

Figure 1. Experimental Set-Up for Breathing Simulator Testing.

may require tilting the breathing simulator and filter holder. Set the breathing simulator to generate the specified breathing pattern.

Start the breathing simulator and at the beginning of an inhalation cycle, start the nebulizer. Operate the nebulizer for a defined initial time period. The length of the time interval ensures that sufficient drug substance is deposited on the inhalation filter for quantitative analysis. A time of 60 ± 1 s typically enables direct determination of the drug substance delivery rate. The time chosen, usually 60 ± 1 s, must allow sufficient drug substance deposition on the inhalation filter to allow quantitative analysis. If the quantity of drug substance deposited on the inhalation filter in 60 s is insufficient for this analysis, the length of the time interval for aerosol collection can be increased. If the filter is soaked with the product, this time can be decreased. At the end of this initial period, stop the nebulizer.

Place a fresh filter and filter holder in position and continue until nebulization ceases. Interrupt nebulization and exchange filters, if necessary, to avoid filter saturation.

Results

Using a suitable method of analysis, determine the mass of drug substance collected on the filters and filter holders during each time interval. Determine the drug substance delivery rate by dividing the mass of drug substance collected on the first inhalation filter by the time interval used for collection. Determine the total mass of drug substance delivered by summing the mass of drug substance collected on all inhalation filters.

AERODYNAMIC ASSESSMENT OF NEBULIZED AEROSOLS

Nebulized products need to be size-characterized at flow rates lower than the range that is typically used for powder inhalers and metered-dose inhalers. The CEN standard recommends a flow rate of 15 L/min because this value represents a good approximation to the mid-inhalation flow rate achievable by a healthy adult breathing at 500 mL tidal volume.

Although low-angle laser light-scattering instruments (laser diffractometers) can provide rapid size-distribution measurements of nebulizer-generated aerosols, these techniques do not detect the drug substance. Rather, they measure the

size distribution of the droplets irrespective of their content. This may not be a problem with homogeneous solutions, but it can result in significant error if the product to be nebulized is a suspension, or if droplet evaporation is significant, as can be the case with certain nebulizer types. Cascade impactors enable the aerosol to be characterized unambiguously in terms of the mass of drug substance as a function of aerodynamic diameter. Laser diffraction may be used if validated against a cascade impaction method.

Apparatus 5 (see general information chapter *Aerosols, Nasal Sprays, Metered-Dose Inhalers, and Dry Powder Inhalers* <601>), a cascade impactor, has been calibrated at 15 L/min specifically to meet the recommendation of the CEN Standard and is therefore used for this test.³ Determining mass balance in the same way as for powder inhalers and metered-dose inhalers is not straightforward because the dose is being captured as a continuous output and hence is not included. Recovery experiments must be performed as part of method development and validation. Control of evaporation of droplets produced by nebulizers may be critical to avoid bias in the droplet size assessment process. Evaporation can be minimized by cooling the impactor to a temperature of about 5°, typically achieved by cooling the impactor in a refrigerator for about 90 min.

Typically, at least after each day of use, the apparatus must be fully cleaned, including the inter-stage passageways, because of the greater risk of corrosion caused by the condensation/accumulation of saline-containing droplets on inter-stage metalwork associated with cooling the impactor. All surfaces of the apparatus should be dried after each test, e.g. with compressed air. [NOTE—The micro-orifice collector (MOC) should not be dried with compressed air.]

Apparatus

A detailed description of Apparatus 5 and the induction port is contained in <601>, and includes details of critical dimensions and the qualification process for the impactor (stage mensuration).

A back-up filter in addition to the MOC must be used to ensure quantitative recovery of drug substance from the nebulized aerosol at the specified flow rate of 15 L/min. The filter is located below the MOC (internal filter option), or a

³ Marple VA, Olson BA, Santhanakrishnan K, et al. Next generation pharmaceutical impactor: A new impactor for pharmaceutical inhaler testing. Part III: Extension of archival calibration to 15 L/min. *J Aerosol Med* 2004; 17(4):335–343.

Figure 2. Apparatus 5 for Measuring the Size Distribution of Products for Nebulization.

filter in holder external to the impactor is used to capture any fine droplets that pass beyond the last size fractionating stage. A pre-separator is not used for testing nebulizer-generated aerosols.

Method Validation

Impactor Stage Overloading—During method development and validation, confirm that the volume of liquid sampled from the nebulizer does not overload the impactor. Visual inspection of the collection surfaces on stages collecting most of the droplets may reveal streaking if overloading has occurred. This phenomenon is usually also associated with an increase in mass of drug substance collected on the final stage and back-up filter. Reducing the sampling period (T_0) is the most effective way to avoid overloading in any given system, balancing overloading with analytical sensitivity.

Re-entrainment—Droplet bounce and re-entrainment are less likely with nebulizer-produced droplets than with solid particles from inhalers, thus coating would not normally be required.

Procedure

Pre-cool the assembled impactor and induction port in a refrigerator (set at about 5°) for not less than 90 min, and start the determination within about 5 min of impactor removal from the refrigerator. Other methods that maintain the impactor at a constant temperature (e.g. use of a cooling cabinet) can also be employed when validated.

Set up the nebulizer with a supply of driving gas (usually air or oxygen), or use a compressor at the pressure and flow rate specified by the manufacturer of the nebulizer. Ensure that the gas supply line does not become detached from the nebulizer when under pressure. Fill the nebulizer with the volume of the medicinal product as specified in the patient instructions.

Remove the impactor from the refrigerator. Attach the induction port to the impactor, and connect the outlet of the impactor/external filter to a vacuum source that is capable of withdrawing air through the system at 15 L/min, as specified in Figure 2. Turn on the flow through the impactor.

Connect a flow meter, calibrated for the volumetric flow leaving the meter, to the induction port. Adjust the flow control valve located between the impactor and the vacuum source to achieve a steady flow through the system at 15 L/min ($\pm 5\%$). Remove the flow meter.

Position the nebulizer in the same orientation as intended for use, then attach the mouthpiece of the nebulizer to the induction port, using a mouthpiece adapter if required. Switch on the flow/compressor for the nebulizer. Sample for a predetermined time (T_0). Once determined, this time (T_0) must be defined and used in the analytical method for a particular drug product to ensure that mass fraction data can be compared. At the end of the sampling period, switch

off the driving gas flow/compressor to the nebulizer, remove the nebulizer from the induction port, and switch off the flow from the vacuum source to the impactor. Dismantle the impactor and, using a suitable method of analysis, determine the mass of drug substance collected in the induction port on each stage and on the back-up filter as described for Apparatus 5 (see <601>). Add the mass of drug substance collected in the MOC to that deposited on the back-up filter/external filter and treat as a single sample for the purpose of subsequent calculations.

Calculate the fine particle mass of the drug substance based on the predetermined time (T_0). Calculate the mass fraction ($F_{m,comp}$) of the drug substance deposited on each component of the impactor, commencing with the induction port and proceeding in order through the impactor, using the following expression:

$$F_{m,comp} = m_{comp}/M$$

m_{comp} = mass associated with the component under evaluation;

M = total mass collected by the system.

Present $F_{m,comp}$ in order of location within the measurement equipment, beginning at the induction port and ending with the back-up filter of the impactor (see Figure 3). $F_{m,comp}$ values for adjacent stages of the impactor may be combined in order to report the mass fraction collected on a group of stages as a single value.

Figure 3. Example of Mass Fraction of Droplets Presented in Terms of Location within the Sampling System.

Determine the cumulative mass-weighted particle-size distribution of the aerosol size-fractionated by the impactor in accordance with the procedure given in <601>. Starting at

the filter, derive a cumulative mass versus effective cut-off diameter of the respective stages (see Table 2 for the appropriate cut-off diameters at 15 L/min). Plot the cumulative fraction of drug substance versus cut-off diameter in a suitable format, e.g., logarithmic or log-probability format. Where appropriate, use this plot to determine by interpolation the fraction either less than a given size or between an upper and lower size limit.

Table 2. Cut-off Sizes for Apparatus 5 at 15 L/min

Stage	Cut-off Diameter (μm)
1	14.1
2	8.61
3	5.39
4	3.30
5	2.08

7	0.98

If necessary, and as appropriate, use this plot to determine values for the mass median aerodynamic diameter (MMAD) and the geometric standard deviation (GSD).

<1644> THEORY AND PRACTICE OF ELECTRICAL CONDUCTIVITY MEASUREMENTS OF SOLUTIONS

This general chapter provides information in support of instrumental methods for procedures that measure electrical conductivity. Pharmaceutical applications include: chemical dosing, cleaning in place, fermentation control, and liquid mixing verification, among others. Although the general chapter focuses on aqueous systems, conductivity measurements can be extended to organic fluids. The general chapter also focuses on contacting conductivity measurements and does not cover applications which may use noncontacting inductive conductivity. After an introduction, the general chapter covers the following major topics: theory of operation, operational considerations, calibration, and operation for at-line, in-line, and off-line measurement procedures.

INTRODUCTION

Conductivity is the measurement of the ability of a fluid to conduct electricity via its chemical ions. The ability of any ion to electrically conduct is directly related to its ion mobility. Some of the common applications of conductivity measurements include water treatment and purification, clean-in-place process fluid management, fermentation process monitoring, dosing applications, nutrient media preparation, buffer production (e.g., distribution and dilution for dialysis and chromatography applications), chromatography detection of gradient and eluent, active pharmaceutical ingredient chemical synthesis, and concentration determination of basic chemicals. Fluids should be measured in a single homogeneous phase—i.e., conductivity should not be applied to mixed immiscible fluids unless they are separated. Electrical conductivity measurements cannot be applied to solids or gases, but they can be applied to the condensate of gases.

Besides its use to monitor ionic concentrations of process fluids, conductivity is also useful for the detection of ionic impurities in compendial waters (see *Water Conductivity* <645>) and for the detection of ionic impurities in organic matrices.

The measurement is non-ion-specific, and all ions respond with different efficiency or equivalent conductance, λ . Despite the lack of ionic specificity, conductivity is a valuable laboratory and process tool for measurement and control of total ionic content because it is proportional to the sum of the concentration of each ionic species (anions and cations) as described in Equation 1:

$$\kappa = 1000 \sum_i^{\text{all ions}} C_i \lambda_i$$

where κ is the conductivity (S/cm), C_i is the concentration of chemical ion i (mole/L), and λ_i is the specific conductance of ion i (S · cm²/mole). Though S/m is the appropriate SI unit for conductivity (i.e., the base SI units are the ampere and the meter) units of S/cm historically have been selected as the accepted unit of expression.

At low ion concentrations (typically <10⁻³ mole/L), the conductivity-concentration relationship is linear and valid because λ is constant for each ion, but there are three notable exceptions to this strict linearity and proportionality. First, at higher concentrations (approximately 10⁻³ to 1 mole/L) small negative deviations from linearity (<5% per decade) arise because of the decrease in λ for each ion, and the negative deviations vary from ion to ion. Second, at higher concentrations for weak acids and bases the extent of dissociation into ions decreases depending on their dissociation constants. As the concentration of a weak acid/base increases, the conjugate cation/anion concentration increases as the square root of the acid/base concentration. Third, at high concentrations (>20%) of certain strong acids such as HNO₃ and H₂SO₄, the negative deviations persist, and, in some cases, the conductivity decreases with increasing concentration. The conductivity of high-concentration acid systems is well documented.

Another variable that influences conductivity measurements is the fluid temperature. A stricter expression of Equation 1 is shown below as Equation 2:

$$\kappa(T) = 1000 \sum_i^{\text{all ions}} C_i(T) \lambda_i(T)$$

where the conductivity measurement, ion concentrations, and specific ion conductances are temperature (T) dependent. As fluid temperature increases, the ions become more efficient electrical conduits, making this physicochemical phenomenon the predominant reason for the temperature-compensation requirement when testing conductive fluids. The specific ion conductance of all ions increases with increasing temperature. In addition, the concentration of ions can also change as a function of temperature. For example, the auto-dissociation constant of water, K_w , increases with temperature from 0° to 100°, resulting in the increased production of H⁺ and OH⁻.

Strictly speaking, it is challenging to temperature-compensate perfectly the conductivity measurement to a reference temperature unless the ionic species are well known. In many applications the ionic species are well known, and in most other cases simple assumptions make this issue less demanding. Temperature compensation is discussed in further detail in *Temperature Compensation*, below.

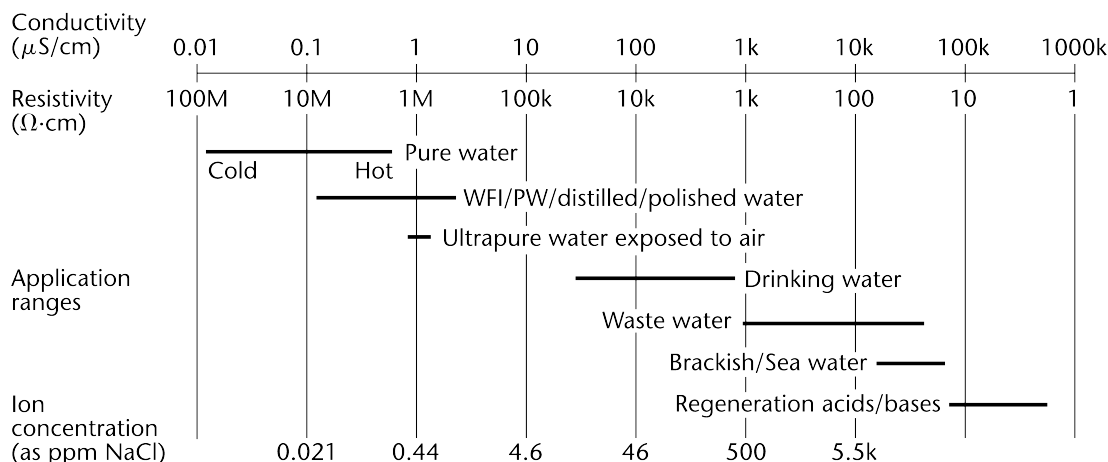

Figure 1. Relationships among conductivity, resistivity, and some example process fluids of various grades of purity.

THEORY OF OPERATION

Alternating Current Measurement Method

Conductivity is measured by applying a voltage (or current) between two conducting electrodes and measuring the resistance of the fluid using Ohm's Law. Various methods are used to apply the voltage/current, but all have the property of using an alternating voltage/current (AC) in order to minimize polarization (or collection of ions) at the electrodes or any electrolytic reaction. If a direct voltage/current (DC) is used, then the positive ions will collect at the negative electrode, and negative ions will collect at the positive electrode. The collection of ions at the electrode prevents the flow of current and adversely affects the accuracy and stability of the conductivity measurement. The measuring frequency of the AC signal depends on the technology and can range from as low as 30 Hz in low-conducting fluids and up to 4 kHz in highly conductive fluids. The specific frequencies are not relevant to operation of the system because the drive frequency is embedded in the instrument's measurement systems and is integrally linked to the supplier's measurement technology. This chapter does not seek to evaluate different measurement technologies because they are usually microprocessor-controlled systems and are proprietary.

The two-electrode AC measurement technique is valid for use with all concentrations of ionic species ranging from acids and bases (high conductivity) to *Water for Injection* and *Purified Water* (low conductivity) and even to organic, weakly ionic species such as alcohols and glycols. The measurement can be sensitive to ion concentrations as low as 0.05 μg/L. For high ion concentrations, analysts can use an alternative 4-electrode measurement method in which the current is applied between two of the electrodes and the voltage is measured between the two other electrodes. Ions are driven to the current electrodes while the voltage electrodes make the measurement with limited polarization effects.

Units of Expression

There is no difference in the physical measurement of conductivity and resistivity—they are multiplicative inverse measurements of each other. Therefore, if one measurement is known, then the other value is readily calculated by taking the reciprocal of the numerical value and the units. There is also no difference in the instrumentation or the sensors. The only difference is how the measured value is reported or displayed for the convenience of the analyst. For

example, $18.2 \text{ M}\Omega \cdot \text{cm} = 0.0550 \text{ }\mu\text{S/cm}$ and $5.23 \text{ k}\Omega \cdot \text{cm} = 0.191 \text{ mS/cm} = 191 \text{ }\mu\text{S/cm}$. Although the proper SI units are $\Omega \cdot \text{m}$ or S/m , the traditionally used units are $\Omega \cdot \text{cm}$ or S/cm .

Figure 1 shows relationships among conductivity, resistivity, and some example process fluids of various grades of purity. The conductivity of fluids in pharmaceutical systems varies over approximately 8 orders of magnitude. In high-purity water systems, the quantity of ions present in *Purified Water* or *Water for Injection* is very low, resulting in a conductivity $<5 \text{ }\mu\text{S/cm}$ and often approaching $0.055 \text{ }\mu\text{S/cm}$ or less. [NOTE—The conductivity of the purest waters at temperatures less than 25° is less than $0.055 \text{ }\mu\text{S/cm}$.] In drinking waters, the conductivity may vary from 30 to 2000 $\mu\text{S/cm}$. In chromatographic separations, the conductivity of the eluent may vary from 0.1 to 100 mS/cm . For hot concentrated acids, the conductivity may be as high as 1 S/cm .

Cell Constant Determination

The purpose of the sensor's cell constant is to normalize the conductance/resistance measurement for the geometrical construction of two electrodes. When two electrodes are placed in a conducting fluid and a voltage is applied to them, there is a conductance (resistance) between the electrodes. If the electrodes are placed farther apart, the conductance decreases (resistance increases). If the area of the electrodes increases, then the conductance increases (resistance decreases). In both cases, the ion concentrations between the electrodes do not change, but the geometrical construction of the sensor (cell constant) alters the measured conductance (resistance). The conductivity of a solution (κ , S/cm) is related to the conductance, G (siemens) according to Equation 3:

$$\kappa = G \times \left(\frac{d}{A} \right) = G \times \theta$$

where A is the area of the conducting electrodes (cm^2) and d is the distance between the electrodes (cm). The other common unit of expression is the reciprocal of conductivity, or resistivity, ρ ($\Omega \cdot \text{cm}$), as described in Equation 4:

$$\rho = \frac{1}{\kappa} = \frac{1}{G \times \theta} = \frac{R}{\theta}$$

where R is the resistance of the fluid between the electrodes ($1 \text{ }\Omega = 1 \text{ S}^{-1}$). The geometrical ratio, d/A (or θ), is known as the cell constant (cm^{-1}) of the sensor.

Determination of the cell constant by the direct measurement of d and A is impractical because of variations in the geometrical configurations and the nonuniformity of the electric field between the electrodes. Practically, the cell constant is determined by the measurement of aqueous solutions of known conductivity. See *Calibration* below.

Temperature Compensation

Temperature compensation is a typical requirement for most conductivity measurements, although there are exceptions such as those contained in *Water Conductivity* <645>. As noted previously, the conductivity of a fluid is related to its temperature. As the temperature increases, ions become more mobile and the conductivity increases. The effect of temperature depends on the type and concentration of the ion, but for most solutions $>10 \mu\text{S}/\text{cm}$ the impact of temperature is in the range of $1.9\%/^{\circ}$ to $2.2\%/^{\circ}$. For strong acids, this may be as low as $1.5\%/^{\circ}$. For high-purity compendial waters, the temperature coefficient varies from $2.0\%/^{\circ}$ to $7.5\%/^{\circ}$ depending on the temperature and purity of the water. For each case described here, some knowledge of the type of impurity is needed in order to ensure adequate temperature compensation. If the conductivity vs. temperature function is linear and the temperature coefficient is constant, the equation that relates the compensated conductivity to the non-temperature-compensated conductivity is described in *Equation 5*:

$$\kappa_{25} = \frac{\kappa_T}{[1 + \alpha(T - 25)]}$$

where T is the measured temperature, κ_{25} is the conductivity compensated to 25° , κ_T is the conductivity at T , and α is 0.02 for a temperature coefficient of $2\%/^{\circ}$.

Most conductivity measurement systems measure the uncompensated conductivity/resistivity and the temperature, and the temperature-compensated conductivity is determined via mathematical algorithms (e.g., by application of *Equation 5*) in the microprocessor of the transmitter. Depending on the application and knowledge of the content of the fluid, different compensation algorithms may be available. For most process control applications, temperature compensation is recommended because when the uncompensated conductivity changes it is impractical to distinguish whether this change is caused by temperature fluctuation or a change in ionic content. Temperature compensation allows the analyst to distinguish between changes in temperature and ionic content. Compensation to a reference temperature of 25° is standard practice, but some methods specify temperature compensation to 20° .

Most conductivity sensors have temperature devices such as a platinum RTD (resistance temperature device) or NTC (negative temperature coefficient) thermistor embedded inside the sensor, although external temperature measurement is possible.

OPERATIONAL CONSIDERATIONS

System Components

The usual components of a conductivity measurement system are the sensor, the transmitter, and the cable that connects the sensor to the transmitter. The sensor is the device that is in direct contact with the fluid. The sensor consists of the electrodes, usually an embedded temperature device, and a process connection (e.g., a tri-clamp if the sensor is intended for in-process sanitary applications). Traditionally, sensors are passive electromechanical devices and do not contain measurement circuitry. The transmitter is the device that measures the resistance between the sensor's

electrodes, measures the resistance of the temperature-measuring device, converts the resistance measurement to a conductivity (or resistivity), and performs temperature corrections to compensate the signal to a reference temperature. The cable connects the sensor to the transmitter. In process control or monitoring systems, the cable allows the sensor to be attached to a process tank or pipe, and the transmitter can be located at a control panel or other remote location, if necessary. The distance between the sensor and the transmitter may affect measurement accuracy caused by the added cable resistance and the susceptibility of the cable to external noise. Therefore, this distance should be considered during selection of the measurement system. In some conductivity measurement systems, the measurement circuitry is directly attached to the conductivity sensor, allowing digital transfer of the measurement results to a remote display at greater distances than traditional measuring systems with wire transmission of analog signals.

Materials of Construction

The sensor's materials of construction are critical when the sensor may be in contact directly or indirectly with the product. For most laboratory applications, materials of construction are less critical. All sensors contain measuring electrodes and an insulating material between the electrodes. Technically, the only requirements are for electrodes to be electrically conducting and to be able to withstand the physical and chemical environment. Electrodes can be made of various grades of stainless steel, titanium, graphite, and many other metals. The insulating materials must isolate the electrodes from each other so that only the fluid conductivity is measured. Insulating materials are usually made of an inert polymer, epoxy, or ceramic.

If the sensor is connected directly to a process vessel or the piping system, then the sensor's materials of construction must meet the thermal and hydraulic (pressure) requirements of the process system. The sensor must have a proper process connection to the vessel/piping. Depending on the application, the sensor also may be required to meet biological compatibility, material, or hygienic design requirements. The sensor must not degrade during installation and operation. The sensor must be able to withstand any other processes that the system may encounter such as clean-in-place or steam-in-place processes. Otherwise analysts may need to remove the sensor from the process. When immersion of the sensor into the process places the process at risk, the sensor should be installed in a housing that is attached to the sidestream. In this case, a fraction of process fluid flows to the housing and sensor and then to drain. This allows indirect measurement of the process fluid without harm to the process or product.

If the conductivity measurement is performed off-line, e.g., in a laboratory environment, then the operating considerations are reduced because the thermal, hydraulic, and other product-contact concerns are reduced or eliminated.

CALIBRATION

The process of calibrating a complete conductivity measurement system generally consists of three parts. First, the transmitter's electronic circuitry is calibrated. Second, the temperature sensor device is calibrated. Third, the cell constant of the conductivity sensor is determined. In each case, verification may precede any calibration to determine if an adjustment is necessary. In most cases for microprocessor-controlled instrumentation, there is no formal mechanical or electronic adjustment of these subsystems. Instead, these adjustments are usually made in software-controlled calibrations that are computed automatically by the transmitter.

A calibrated transmitter should be used in order to calibrate the temperature sensor and cell constant. The transmitter used to calibrate the temperature sensor and cell

constant can be the transmitter used in normal operation, or another transmitter can be used instead. Because of differences in a supplier's wiring and electronic compatibility, it may be necessary to use the same type of transmitter.

As is the case for all instrument-based methods, calibration frequency depends on many factors. Depending on the type of conductivity sensor and transmitter, calibration cycles vary from weekly to annually based on manufacturers' recommendations, historical performance of the instrumentation, internal requirements, and the criticality of the application. For robust process instrumentation, typical calibration cycles for the electronics and the sensor take place approximately every 12 months. When the sensor's cell constant can be altered by the fluid or the process conditions, more frequent calibration may be needed.

Instrument Calibration

The transmitter's electronic circuitry is calibrated by disconnecting the sensor from the transmitter, connecting precision resistors (resistors of known value) to the transmitter, and comparing the traceable resistance value to the measured resistance value. The resistance values should be traceable to a competent national authority. The resistance values should be selected so that they are in the range of (1) the measurement capability of the transmitter, and (2) the resistance that will be measured during operation. The transmitter may have multiple circuits internally, so verification of the appropriate circuit (or all circuits) and measurement range is necessary. Comparison of the measured resistance to the actual resistance verifies if the transmitter is properly calibrated. The resulting difference must be within a predetermined $x_1\%$ of the actual resistance, where x_1 indicates the desired conductivity circuit electronics performance. Typical conductivity circuit electronics performance is usually in the range of 2% or less of the target value. Otherwise, adjustment of the resistance measurement circuit is recommended.

An example of the transmitter's measurement electronics calibration process follows: A typical operating range for a clean-in-place process may be in the 50 to 75 mS/cm range. A sensor with a cell constant of 5.0 cm^{-1} is used in this example. Based on Equation 4, this requires a measuring resistance of 67 to 100 Ω . To verify the conductivity measuring circuit during calibration, analysts should use a resistor(s) with a traceable value in or near this range. When compendial waters are used, typical measurements are in the range of 1 to 20 $\text{M}\Omega \cdot \text{cm}$ and use sensors with a cell constant of 0.1 cm^{-1} . This computes to a resistance of 0.1 to 2 $\text{M}\Omega$. Resistors with a traceable value in this range should be used. If the recorded values are within the range of the pre-established acceptance criteria ($x_1\%$), then adjustment is not required.

Temperature Measurement and Sensor Calibration

If a temperature measurement circuit is integrated into the transmitter and is used as part of the measurement system, then verification and/or calibration of this circuit is required. Depending on the type of temperature device in the sensor, an appropriate signal source (e.g., resistance) should be input to the transmitter. Comparison of the measured temperature and the simulated temperature verifies if the temperature measurement circuit is properly calibrated. The resulting difference must be within x_2° of the simulated temperature where x_2 indicates the desired temperature circuit electronics performance. Typical temperature circuit electronics performance usually is in the range of $\pm 1^\circ$ or less. If the difference meets the pre-established acceptance criteria, no further action is required. Otherwise, adjustment of the temperature measurement circuit is recommended using the protocol in the transmitter's calibration function.

If a temperature sensor is integrated into the conductivity sensor, the temperature sensor can be calibrated by comparison of the sensor's temperature measurement to a reference system. This is accomplished by immersing the process and reference sensors in the same fluid. The reference system can be another traceable temperature measurement device or a fluid system of known temperature such as boiling water (corrected for elevation, if this degree of accuracy is necessary) or an ice-water bath.

The accuracy of the calibration is related to the accuracy of the reference sensor, the thermal homogeneity of the fluid, and the elimination or reduction of any artifacts that can negatively influence accuracy. For example, if the sensor is not fully immersed in the fluid, thermal conduction from the ambient environment can alter the temperature measurement. Careful insulation of the sensor from the ambient environment may improve the accuracy of temperature measurements, particularly if the reference temperature is substantially different than the ambient temperature.

Comparison of the measured temperature and the reference temperature verifies if the temperature sensor is properly calibrated. The resulting difference must be within x_3° of the reference temperature where x_3 indicates the desired temperature accuracy that is required for the process. Temperature sensor accuracy is usually in the range of $\pm 2^\circ$ or less. If the difference meets the pre-established acceptance criteria, no further action is required. Otherwise, adjustment of the temperature sensor calibration factors is recommended using the protocol in the sensor's calibration function.

Cell Constant Calibration

The cell constant of the sensor is determined by comparing the conductivity measurement of the system to that from a reference conductivity system and adjusting the cell constant. Place the sensor in a reference solution of known conductivity whose value is traceable to a competent authority. The reference solution can be a solution of known conductivity in one of three ways:

- (1) The solution can be produced according to a standard method that is traceable to a competent authority. One method is to prepare one of the solutions listed in ASTM D1125. Another method is to use ultra-pure deionized water with no exposure to air whose conductivity is known.
- (2) The solution can be procured from a third-party supplier with traceability to an acceptable authority. Cell constant calibration should be performed in the recommended temperature range of the reference solution.
- (3) The solution can be any fluid whose conductivity is known by measurement from an alternative and traceable reference conductivity measurement system.

In all three cases, regardless of the type of calibration methodology, there are some fundamental requirements. The sensor's cell constant should be calibrated at a conductivity that is in the measurement range of the measuring system. For example, if the system is designed to measure in the 0–100 $\mu\text{S}/\text{cm}$ range, then use of a 1000 $\mu\text{S}/\text{cm}$ reference solution is not advised.

Because the cell constant is a geometrical property of the sensor and is a constant, the determination and/or calibration of the cell constant does not need to be in the operational range of the pharmaceutical process as long as the conductivity is in the operational range of the measurement system. Also, because the cell constant is a geometrical property of the sensor, a single-point calibration typically is sufficient. In some applications, a 2-point calibration can provide improved accuracy at very high conductivity. Depending on the reference solution, cell constant calibration can be performed with or without temperature compensation. For reference solutions exceeding 10 $\mu\text{S}/\text{cm}$, if temperature compensation is needed a temperature coefficient (α)

of 2%/° is sufficient over the range of $25 \pm 10^\circ$ unless otherwise specified.

Adjustment of the cell constant is recommended if the difference between the measured and reference conductivity exceeds $x_r\%$ of the reference conductivity where x_r indicates the conductivity accuracy that is required for the process. Typical conductivity accuracy is 5% or less. If the accuracy measurement meets the pre-established acceptance criteria, no further action is required. Otherwise, adjustment of the sensor's cell constant is recommended using the protocol within the sensor's calibration function.

OPERATION

In-line, At-line, and Off-line Measurements

Depending on the application, in-line, at-line, and off-line measurements have specific universal requirements. Each has advantages and disadvantages depending on the application, but the fundamental technologies (AC measurement) supporting each measurement type are constant. The primary differences between the in-line/at-line and the off-line systems are sensor features related to process robustness and transmitter features related to output functions, external communication capabilities, and system installation costs. In-line and at-line systems have added benefits of real-time measurements and continuous data acquisition. They also have added one-time electrical and plumbing installation costs, and the instrumentation is fixed in a specific location for a single process and purpose. Also, sample is diverted to drain, resulting in product loss. Note that the fluid flow velocity should be high enough that the velocity does not affect the measurement. Off-line (or laboratory-based) systems have the benefit of measuring many sample types under controlled conditions. Off-line batch testing has added costs associated with cleaning containers and collecting samples as well as risks of sample contamination.

In-line conductivity measurements are suitable when the following conditions are met: (1) there is a need for or value of real-time, continuous data; (2) the sensor and the application/fluid are compatible and cause no harm to each other; and (3) atmospheric contamination must be avoided. In these cases, continuous process control, decisions, and intervention are available.

At-line (or sidestream) conductivity measurements are used when the following conditions are met: (1) a need exists for or value of real-time, continuous data; (2) the sensor and the application are compatible with each other; (3) the sensor can cause harm to the application and/or fluid; and (4) atmospheric contamination must be avoided. In such cases the measurement is made by delivering the sample from the tank/piping using hydraulic pressure (flow) to the conductivity sensor, and the fluid passes through the sensor and goes to drain. In these cases, continuous process control, decisions, and intervention are available and have no effect on product or application. The only requirement is positive pressure upstream from the sensor to prevent backstreaming of the sample fluid back into the process.

Off-line conductivity measurements are used when the following conditions are met: (1) no need exists for or value of real-time or continuous data; (2) the sensor and the application are compatible with each other, but the sensor can cause harm to the application and/or fluid; and (3) sampling needs are infrequent or are needed on a limited basis.

Sample Preparation and Off-line Measurement

When performing off-line measurements, analysts must ensure that the container used to collect the fluid sample(s) is sufficiently clean so that the container does not alter the result. Collect an amount of fluid needed for rinsing and measuring. For samples such as *Purified Water* where the

analysis can be affected by gasses, containers should be filled completely to reduce headspace. The volume of fluid needed to make a measurement depends on the design of the sensor and can range from <10 mL to 1 L. Transfer a portion of the sample fluid to the clean measuring container to rinse the container walls. Discard the fluid. The sample container also can be used as the measuring vessel. The sensor should be rinsed with a suitable quality of water or other appropriate fluid before use so the measurement is not affected and then rinsed at least once with the solution to be measured, which then is discarded. This rinse with sample solution removes any residue or fluids with which the conductivity sensor previously was in contact. The exact procedure varies depending on the solution tested. For example, when testing very low conductivity samples such as *Purified Water*, analysts must do more rinsing to remove any remaining residue from the sensor. Maximum holding time, temperature, and container type must be controlled for some low-conductivity samples, e.g., high-purity waters, because of the potential impact of ionic leachables from certain containers.

Transfer the fluid to the measuring container, immerse the sensor into the fluid, and ensure acceptable clearance around the sensor's measurement area. Stir or agitate the sample to prevent bubbles from attaching to the electrodes and disturbing the measurement. If a temperature-compensated measurement is used, then select the appropriate temperature-compensation algorithm in the transmitter, and adjust the sample temperature to the recommended range, if necessary, using an appropriate temperature bath. Otherwise, disable the temperature compensation. Verify that the temperature is sufficiently stable (<0.25° change per min), and record the conductivity reading and the temperature, if necessary.

In-line Measurement

For in-line testing, the sensor is installed into the process piping or vessel. The orientation of the sensor relative to the flow of the fluid is critical to ensure that (1) particles and sediment do not collect between the measuring electrodes, and (2) no air pockets are trapped between the measuring electrodes. Both factors can adversely affect the measurement accuracy. Depending on the electrode design, manufacturers usually provide recommendations. Ensure the sensor is clean before installation.

After the sensor is immersed in the closed process, such as a piping system or tank, the sensor does not require removal and cleaning before a measurement. If a temperature-compensated measurement is used, then select the appropriate temperature-compensation algorithm. Otherwise, disable the temperature compensation. Although temperature stability is desirable, it may not be possible depending on the temperature control of the process. Record the conductivity reading and the temperature, if necessary.

At-line Measurement

For at-line testing, a piece of tubing is used to connect the process vessel/piping to the sensor and its housing. The tubing should be cleaned or flushed with an appropriate cleaning agent to remove any impurities that could alter the conductivity measurement. The tubing can be made of metal or plastic depending on the application and chemical compatibility. Installation of the sensor into a housing permits fluid to be directed into the sensor and then to drain. Installation considerations are similar to those for in-line installations. Ensure the sensor and housing are clean before installation.

After the sensor and housing are connected to the sidestream, the sensor does not require removal and cleaning before a measurement. If a temperature-compensated measurement is used, then select the appropriate temperature-compensation algorithm. Otherwise, disable the tem-

perature compensation. Although temperature stability is desirable, it may not be possible depending on the temperature control of the process. Record the conductivity reading and the temperature, if necessary.

Other Considerations

In all cases mentioned above, the use of abrasive materials to clean the sensor typically is discouraged. Two reasons to avoid abrasive cleaning materials are that (1) the passive layer of stainless steel sensors (when used) can be destroyed, and (2) the surface of the measurement area can affect the measurement accuracy. For these reasons, the use of appropriate chemically compatible fluids is preferred instead of mechanical methods for cleaning.

Unlike the requirements for many electrochemical measurements, the need for flowing, circulating, or agitating fluid is not a fundamental requirement for a conductivity measurement. In general, there is no difference in the conductivity measurement of a static or a flowing sample, but two conditions must be met for static samples: First, bubbles cannot be allowed to collect on the measuring area of the electrodes because they can interfere with the flow of current conductivity measurement. Second, if sample homogeneity is affected by the lack of agitation or circulation, then the conductivity measurement may not represent the conductivity of the bulk fluid.

In all cases, the installation of the sensor should take into consideration wall effects from the vessel, piping, or laboratory container. If the proximity of the wall interferes with the electromagnetic field for the conductivity measurement, then the measurement could be positively or negatively altered. Some 2-electrode sensor designs, such as coaxial concentric electrodes, are not affected by nearby objects. The sensor's installation instructions may indicate if this must be considered.

If unstable conductivity readings are observed, some common causes could be inadequate grounding of the water system, electronic noise from pumps and other high-frequency generators, or internal leakage of the sensor. Various diagnostic approaches are available and can help identify the cause.

Add the following:

▲ (1761) APPLICATIONS OF NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY

PRINCIPLES OF NMR

Nuclear magnetic resonance (NMR) spectroscopy is an analytical technique based on the magnetic properties of

certain atomic nuclei. NMR is similar to other types of spectroscopy in that absorption of electromagnetic energy at characteristic frequencies provides analytical information. NMR differs from other types of spectroscopy because the discrete energy levels between which the transitions take place are created by placing the nuclei in a magnetic field of strength H_0 . Although the initial field strength of the applied field is H_0 , when the sample is inserted into the magnet, the field strength throughout the sample becomes B_0 , defined as follows:

$$B_0 = \mu_s H_0 \quad [1]$$

in which μ_s is the magnetic susceptibility of the sample.

Atomic nuclei behave as if they were spinning on the nuclear axis. The angular momentum, ρ , of the nucleus is characterized by a spin quantum number (I). The maximum observable component of the angular vector, ρ , is

$$\rho = \hbar/2\pi = I\hbar \quad [2]$$

in which \hbar is Planck's constant and \hbar is modified Planck's constant.

Table 1 shows the values of I as a function of the mass number and the atomic number.

Table 1. Nuclear Spin Values as a Function of Mass and Atomic Numbers

Mass Number	Atomic Number	Nuclear Spin (I)
Odd	Even or odd	1/2, 3/2, 5/2 ...
Even	Even	0
Even	Odd	1, 2, 3 ...

The angular momentum creates a magnetic moment, μ , which is parallel to and directly proportional to ρ .

$$\mu = \gamma\rho = \gamma\hbar I \quad [3]$$

where γ is the magnetogyric ratio and is a constant for all nuclei of a given isotope, regardless of their position in a molecule.

Nuclei that have a spin quantum number $I \neq 0$, when placed in an external uniform static magnetic field, align with respect to the field in $(2I + 1)$ possible orientations. Thus, for nuclei with $I = 1/2$, which includes most isotopes of analytical significance (Table 2), there are two possible orientations, corresponding to two different energy states. The energies of these two states are $\pm \mu B_0$, and their separation is

$$E = \mu B_0 - (-\mu B_0) = 2\mu B_0 \quad [4]$$

with more nuclei populating the lower energy state ($-\mu B_0$) than the higher energy state ($+\mu B_0$). The populations are in accordance with the Boltzmann distribution:

$$N_+/N_- = \exp(-E/kT) \quad [5]$$

where N_+ and N_- are the populations of the high and low energy states, respectively; k is the Boltzmann constant; and T is the temperature in K.

Table 2. Properties of Some Nuclei Amenable to NMR Study

Nucleus	<i>I</i>	Natural Abundance (%)	Sensitivity	Resonance Frequency (MHz) at		
				1.4093 T ^a	7.0463 T	11.7440 T
¹ H	1/2	99.98	1.00	60.000	300.000	500.000
¹³ C	1/2	1.108	0.0159	15.087	75.432	125.721
¹⁹ F	1/2	100	0.83	56.446	282.231	470.385
³¹ P	1/2	100	0.0663	24.289	121.442	202.404
¹¹ B	(3/2)	80.42	0.17	19.250	96.251	160.419

^a T = tesla: 1.4093 T = 14.093 kilogauss.

A nuclear resonance is the transition between these states, and upward as well as downward transitions are possible. In a static magnetic field the nuclear magnetic axis precesses (Larmor precession) about the B_0 axis. The precessional angular velocity is often referred to as the Larmor frequency, ω_0 , and is related to B_0 :

$$\begin{aligned}
 E &= h\nu = 2\mu B_0 \\
 &= 2\gamma\hbar B_0 \\
 &= \gamma\hbar B_0 \\
 \nu &= \gamma B_0 / 2\pi \\
 \omega_0 &= \gamma B_0 \quad [6]
 \end{aligned}$$

If energy from an oscillating radio-frequency (rf) field is introduced, then resonance is achieved when the rf frequency is the same as the precessional angular velocity. Although the probability of an upward transition is equal to that of a downward transition, more upward transitions take place than downward transitions because N_- is greater than N_+ . Hence, an overall absorption of energy takes place. As shown in Table 2, the resonance frequency of a nucleus increases in direct proportion with the increase of the magnetic field strength.

NMR is a technique of high specificity but relatively low sensitivity. The basic reason for the low sensitivity is the comparatively small difference in energy between the upper and lower energy states (0.08 Joules at 1.5 to 2.0 T field strength), which results in a population difference between the two levels of only a few parts per million. Another important aspect of the NMR phenomenon, with negative effects on sensitivity, is the long lifetime of most nuclei in the excited state. Long lifetimes affect the design of the NMR analytical test, especially in repetitive pulsed experiments. Simultaneous acquisition of the entire range of resonant frequencies instead of frequency-swept spectra can give increased sensitivity per unit time.

All characteristics of the signal—chemical shift, multiplicity, linewidth, coupling constants, relative intensity, and relaxation time contribute analytical information. The analytical usefulness of NMR arises from the observation that the same types of nuclei, when located in different molecular environments, exhibit different resonance frequencies. The reason for this difference is that the effective field associated with a particular nucleus is a composite of the external field provided by the instrument and the field generated by the circulation of the surrounding electrons. The latter field is generally opposed to the external field and lowers the overall field strength at the nuclear site. The phenomenon is termed *shielding*. Hence, the more shielded nuclei have lower Larmor frequencies.

It is not convenient to accurately measure the absolute values of transition frequencies, as is done with other spectroscopic procedures. However, it is convenient to accurately measure the difference in frequencies between two resonance signals. The position of a signal in an NMR spec-

trum is described by its separation from another resonance signal arbitrarily taken as standard. This separation is called *chemical shift*, which may be expressed in units of magnetic field or in frequency units that are readily interconverted by the equation for the resonance condition, Equation 6. This equation shows that when the separation is expressed in frequency units, it is directly proportional to the field strength. It is more convenient, therefore, to express the chemical shift in terms of the dimensional unit δ , which is independent of the field strength, and is defined by

$$\delta = (v_{ss} - v_{rs})/v_0 \quad [7]$$

where v_{ss} is the test substance resonance frequency, in Hz; v_{rs} is the reference resonance frequency in Hz; and v_0 is the instrument frequency, in MHz. When v_0 is expressed in units of MHz, then Equation 7 is expressed in units as parts per million (ppm). Hence, it is common to use the unit ppm to express the chemical shift difference between the resonance peak of the test substance and that of the reference.

By using this equation, one can use (with appropriate caution) the chemical shift of any known species (such as the residual ¹H-containing species in a deuterated solvent) as a chemical shift reference. This equation, now in common use, is applicable to nearly all nuclei.

Tetramethylsilane (TMS) is the most widely used chemical shift reference for proton and carbon spectra. It is chemically inert, exhibits only one peak (which is more shielded than most signals), and is volatile, which allows ready specimen recovery. Either 2,2,3,3- d_4 sodium 3-(trimethylsilyl)propionate (TMSP) or sodium 2,2-dimethyl-2-silapentane-5-sulfonate (DSS) is used as an NMR reference for aqueous solutions. The resonance frequency of the TMSP or DSS methyl groups closely approximates that of the TMS signal. Where the use of an internal NMR reference material is not desirable, an external reference may be used, such as a reference standard in a separate NMR tube.

Conventional NMR spectra are shown with shielding increasing and chemical shift decreasing from left to right because less shielded nuclei have higher Larmor frequencies than do more shielded nuclei. Resonances on the left are said to be deshielded (i.e., they show lower electron density). Resonance peaks appearing at the right are termed more shielded (i.e., they show greater electron density) than those appearing at the left. Resonances from the more shielded and the less shielded nuclei often are inappropriately called the high-field or upfield peaks and the low-field or downfield peaks, respectively, as a result of the outdated method of acquiring data by sweeping the magnetic field. Today, the overwhelming majority of spectra are acquired on a pulsed Fourier transform (FT) spectrometer, which sweeps neither the magnetic field nor the transmitter frequency. Therefore, it is more appropriate to refer to resonances at the left side of the spectrum as high-frequency or deshielded resonances and those on the right as low-frequency or shielded resonances.

The coupling between two nuclei can be described in terms of the spin-spin coupling constant, J , which is the separation (in Hertz) between the individual peaks of the multiplet. When two nuclei interact and cause reciprocal

splitting, the measured coupling constants in the two resulting multiplets are equal. Furthermore, J is independent of magnetic field strength.

Coupled spin systems are usually referred to as weak or strong. These terms depend on the separation of the Larmor frequencies of the coupled nuclei compared to the coupling constant between them. Both of these values are easily measured from the spectrum. For a weakly coupled system, the separation expressed in Hz ($\Delta\nu$) is large compared to J , which is always expressed in Hz. Thus, the ratio of the two is dimensionless. For a weakly coupled system, the ratio is large. Typically, spectroscopists consider a ratio above 10 to be weak. Only weakly coupled spin systems produce first-order spectra, which are comparatively easy to analyze. The number of individual peaks that are expected to be present in a multiplet and the relative peak intensities are predictable. The number of peaks is determined by $2nI + 1$, where n is the number of identical nuclei on adjacent groups that are active in splitting and I is the spin of those nuclei causing the splitting. For protons this becomes $(n + 1)$ peaks. In general, the relative intensity of each peak in the multiplet follows the coefficient of the binomial expansion $(a + b)^n$. These coefficients can conveniently be found by use of Pascal's triangle, which produces the following relative areas for the specified multiplets: doublet, 1:1; triplet, 1:2:1; quartet, 1:3:3:1; quintet, 1:4:6:4:1; sextet, 1:5:10:10:5:1; and septet, 1:6:15:20:15:6:1. Two examples of first-order spectra arising from weak coupling are shown in Figure 1.

Figure 1. Diagrammatic representation of simple spectra resulting from weakly coupled spin systems.

Coupling may occur between ^1H and other nuclei, such as ^{19}F , ^{13}C , and ^{31}P . This type of coupling can frequently be observed between nuclei separated by 1–5 bonds.

Magnetically active nuclei with $I \geq 1$, such as ^{14}N , possess a nuclear quadrupole moment, which produces line broadening of the signals from neighboring nuclei.

Another characteristic of an NMR signal is its relative intensity, which has wide analytical applications. In carefully designed experiments, the area or intensity of a signal is directly proportional to the number of protons that give rise to the signal. As a result, NMR can be used for quantitation (see *Quantitative Analysis* in this chapter and in *Nuclear Magnetic Resonance, Qualitative and Quantitative NMR Analysis* (761)). NMR spectra may contain spinning side bands,

peaks that appear symmetrically located around each signal. These signals are due to the failure to optimize the off-axis (x and y) shims. The homogeneity of modern superconducting magnets, coupled with computer shimming techniques, reduce the need for sample spinning and completely eliminate these sidebands.

NMR SPECTROMETERS

Introduction

NMR spectrometers have evolved since the first commercial instrument, a Varian HR-30 that operated at 30 MHz, was produced in 1952. Initially NMR spectrometers used a data acquisition technique known as continuous wave (CW), which was based on sweeping the magnetic field. The limitations of a CW spectrometer include low sensitivity and long analysis time.

Today's spectrometers operate at frequencies up to 1 GHz and apply an rf pulse to the sample to produce a time-domain signal known as a free induction decay (FID), which is then Fourier transformed into a frequency-domain signal. This technique is known as FT NMR spectroscopy. Current NMR spectrometers are composed of several key components: the magnet, the probe, the console, and the computer.

The instruments are described by the approximate resonance frequency of the ^1H resonance, e.g., 600 MHz, or by their field strength, e.g., 14.1 T.

The Magnet

Until the early 1970s, NMR magnets were either ferromagnetic-core electromagnets or permanent magnets that operated at field strengths of 1.41–2.35 T, corresponding to ^1H resonance frequencies of 60, 80, 90, and 100 MHz. The first NMR magnets based on superconducting magnets were introduced in the 1960s and allowed access to much higher field strengths that currently are as high as 23.5 T (1 GHz).

The superconducting magnet is the most expensive component of an NMR spectrometer and can cost up to several million dollars. These magnets consist of miles of Nb_3Sn or NbTi wire. When these materials are wound into a solenoid that is immersed in liquid helium at 4.2 K, they become superconducting. That is, an electrical current can be induced in them by an energizing power supply, and that current will persist for many years even after the power supply is removed. This essentially constant electrical current is used to generate high static magnetic fields that can be several times higher than those obtained with ferromagnetic-core magnets. Ensuring that the superconducting coil is immersed in liquid helium at all times is the only maintenance needed to sustain these high fields.

Figure 2 contains a diagram of a typical superconducting magnet. The superconducting solenoid is immersed in a liquid-helium Dewar at 4.2 K. This unit is itself contained in a liquid-nitrogen Dewar at 77.4 K. Each Dewar is surrounded by a vacuum space and reflective film coating to prevent outside heat of the laboratory from entering the helium Dewar. The central core or room-temperature bore provides room for the stack that contains the shim coils for room-temperature shimming. Finally the probe is inserted into the stack. Samples are injected or ejected from the probe by means of a jet of filtered and dried air or nitrogen.

Figure 2. Schematic representation of a superconducting magnet.

An important recent advance in magnet technology has been the construction of shielded magnets with stray fields that can extend only one or two meters from the center of the magnet in three dimensions, thereby making magnet siting a far easier task than it was with unshielded magnets.

In addition to the main solenoid, the helium Dewar also contains several other superconducting coils that are used to shim the main magnetic field as a first step in attaining very high field homogeneity. Further shimming is accomplished by 20–30 shim coils in the room-temperature shim stack that is inserted in the bore of the magnet. These coils operate at ambient temperature and are used to generate small magnetic fields that oppose and cancel inhomogeneities caused by the surroundings, the probe, or the sample itself. Computer software has taken over a large amount of the tedious job of shimming the magnet homogeneity, a critical task for obtaining good NMR data. Using the lock signal from the sample, spectroscopists can generate a field map for each of the shim coils. Using this map, the computer then calculates the amount of current that should be applied to each of the shim coils to maximize the magnet homogeneity. Typically this operation takes less than a minute for shimming the on-axis (z_1 to z_6) shim coils. The off-axis (x/y) inhomogeneities can be compensated for in a similar manner but usually in a longer period of time (15–20 minutes) because of the larger number of off-axis coils.

The Probe

The NMR probe may be the most important part of the instrument. The probe consists of one or two rf coils. Each coil, which is inductive (L), is in a circuit that contains several tunable capacitive (C) elements. These elements are adjusted to enable the probe to transmit and receive at the Larmor frequency, ν_0 . For a given nucleus, the probe tuning is determined by $[\nu = 1/(2\pi(LC)^{1/2})]$. A pulse of rf at the Larmor frequency results in an applied magnetic field (B_1). To induce a transition, B_1 must be applied perpendicular to the static field generated by the magnet superconducting coil. The rf coil not only transmits the excitation pulse but is also electronically switched to receive the rf signal from the sample.

The most common NMR sample tube is the 5-mm (od) NMR tube. However, probes have been designed in many forms. Some probes can accommodate 10- or 20-mm tubes for samples that are not in limited supply, such as petroleum and polymers. For limited amounts of precious samples, probes have been made to accept tubes as small as 1 mm, which can accommodate solutions as small as 5 μ L. Also, flow probes are available to obtain data directly from a liquid chromatography effluent.

Probes are available in a large number of coil configurations. The most common probe usually contains a broadband observe coil that is tunable over a wide range of frequencies (^3P to ^{109}Ag), a decoupler (^1H) coil, and a coil tuned to deuterium (^2H) for field-frequency lock. Usually, the decoupler coil is double-tuned for both ^1H and ^2H . Probe configurations can include as many as four channels for multidimensional work with biological macromolecules.

The probe can come in a format where the X-nucleus observe-coil (e.g., ^{13}C) is wound closest to the sample for highest sensitivity, and the decoupler coil (^1H) is farther away. The inverse configuration is also available to provide the maximum signal-to-noise (S/N) ratio for ^1H , the detected nucleus in two-dimensional (2-D) indirect heteronuclear experiments, such as heteronuclear single-quantum coherence spectroscopy (HSQC) and heteronuclear multiple-bond correlation (HMBC) where the X-nucleus is indirectly detected via the ^1H frequency. Recent advances in probe technology have resulted in a single probe combining the sensitivity of the direct and inverse detection probes described above. Another advancement in probe design is the cryogenically cooled probe wherein the rf coils and their preamplifiers are held at close to liquid helium temperatures (20 K). Because rf electronics generate lower noise levels at colder temperatures, S/N ratios can be increased by at least a factor of four in these probes. Because the S/N ratio of a spectrum is given by $n^{1/2}$, where n is the number of acquisitions, an enhancement by a factor of four to the initial S/N ratio translates to a savings of 16 in time or to a four-fold reduction in sample size.

Probes can also be equipped with gradient coils that can apply a magnetic field gradient in the z only or x , y , and z directions. These gradients are used to study diffusion or, more commonly, to be integral parts of pulse sequences because they provide an efficient means for selecting specific coherences in 2-D experiments.

In addition to the electronic coils, probes usually come equipped with a heater coil that enables variable temperature work from -100° to $+150^\circ$. Probes also have gas outlets to allow sample insertion and ejection from the probe as well as sample spinning.

For solid-state samples the probes come with cylindrical rotors that are filled with the sample and capped. The entire rotor can then be oriented at an angle of 54.74° (known as the magic angle) relative to the magnetic field direction and spun at rates up to 70 kHz. Rapid rotation at this angle helps remove the chemical shift anisotropy and dipolar coupling so that the very broad resonances observed in the solid state can be reduced considerably.

The Console and Computer

The NMR console has the primary function of generating the various Larmor frequencies required for a given experiment, amplifying and transmitting these frequencies to the probe, and detecting the resulting signals that are transmitted from the probe so that they can be used to create an NMR spectrum. In addition to these primary functions, the console performs many more operations, all of which are computer-controlled. Figure 3 contains a schematic diagram illustrating the various components of the current majority of spectrometer consoles.

The computer continually controls the signal to the lock transmitter (A) so the resonance of the lock material can be detected in the lock receiver to maintain field/frequency

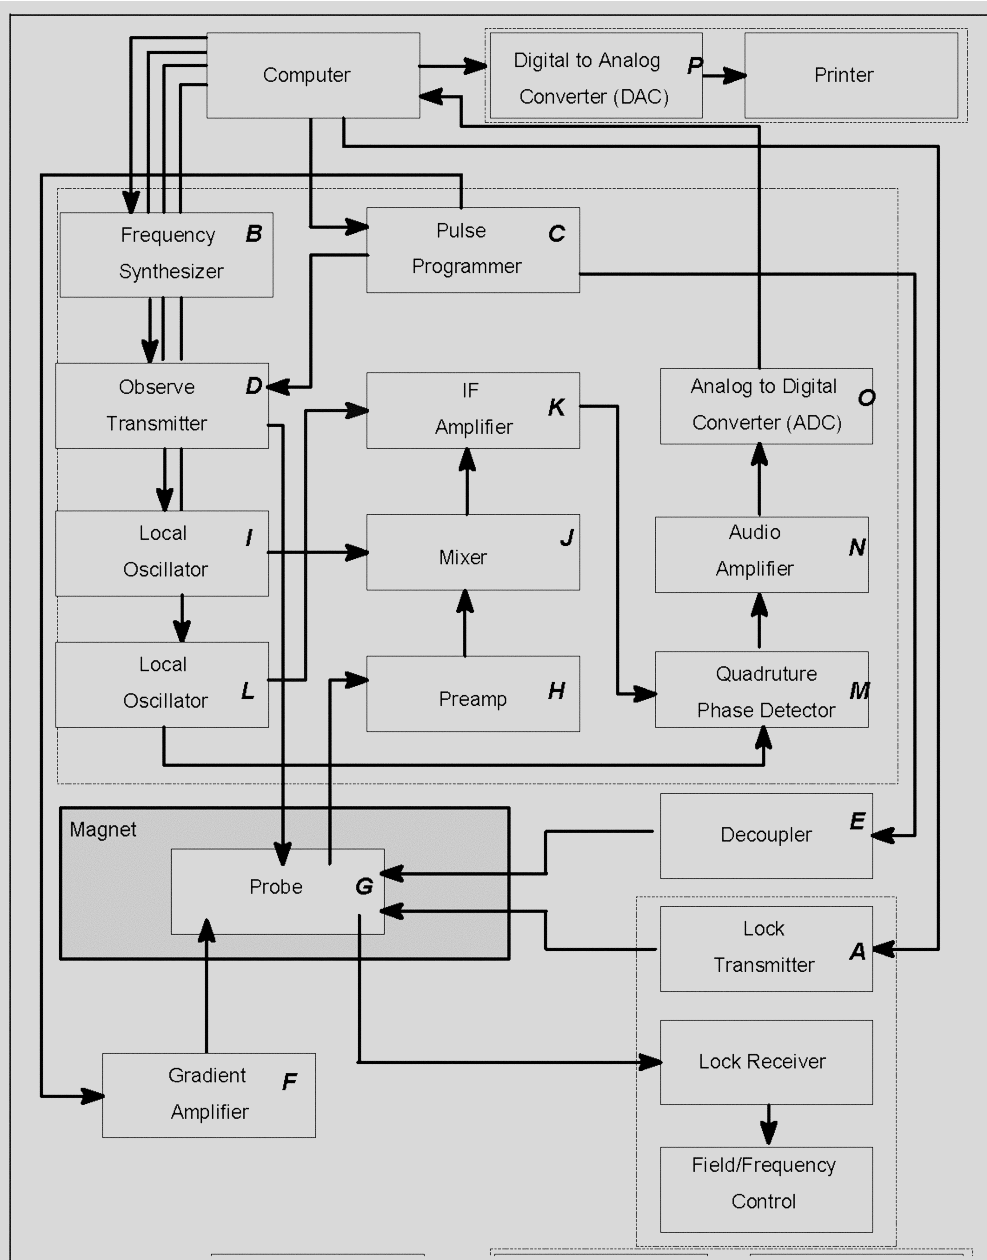

Figure 3. Schematic diagram of an NMR spectrometer.

control. The computer also controls the frequency synthesizer (**B**) that generates the various frequencies that are close to the Larmor frequencies of the observed or perturbed nuclei. For a specific experiment, the computer triggers the pulse programmer (**C**), which, in turn, sends timing signals (pulse width, phase, and shape) to the observer transmitter (**D**), the decoupler (**E**), and the gradient amplifier (**F**), depending on which of these units are needed for that experiment. Once the observed nucleus in the probe (**G**) is excited by a pulse from the observed transmitter, the resultant rf signal is amplified in the preamplifier (**H**). Then the signal is mixed (**J**) with a local oscillator (**I**) to generate a lower rf frequency, called the intermediate frequency (IF) that is further amplified (**K**). A second mixing stage, this time with a different local oscillator (**L**), results in an audio signal that is then detected in quadrature (**M**) before being amplified (**N**), converted (**O**) from an analog to a digital signal, and stored

in the computer. After the signal is processed to create a spectrum, the digital data can be converted back to an analog signal in a digital-to-analog converter (**P**) and printed.

The output from the phase-sensitive detector (**M**) is the free induction decay (FID), which is a time-domain signal, $f(t)$.

When two detectors are used (**M**) with their reference frequencies shifted from each other by 90° , frequencies that are positive with respect to the reference can be distinguished from those that are negative. This system is referred to as quadrature phase-sensitive detection (QPD). Each detector produces an FID, but they will always be 90° out of phase with respect to each other. One FID is called the real FID, and the other is called the imaginary FID. The Fourier transform that is performed in this case is called a complex Fourier transform. The combination of the real and imaginary FIDs yields the frequency spectrum, $F(\omega)$.

$$F(\omega) = \int_{-\infty}^{+\infty} f(t) \exp^{-i\omega t} dt \quad [8]$$

In addition to the Fourier transform process, the computer is also used for post-acquisition processing of the data. The frequency-domain spectrum that results from the complex Fourier transform can then be phased, baseline corrected to remove distortions, integrated to obtain peak areas, and peak picked to provide chemical shift information. The computer is also capable of providing spectra calculated from chemical shift and coupling values, curve-fitting resonances, and deconvoluting complex overlapped peaks. Finally, the digital data can be converted to their analog form by a DAC (O) and printed.

RELAXATION

NMR includes two types of relaxation: *Spin-Spin Relaxation*, sometimes referred to as *Transverse Relaxation*, or T_2 Relaxation, and *Spin-Lattice Relaxation*, sometimes referred to as *Longitudinal Relaxation*, or T_1 Relaxation. At least two mechanisms contribute to *Transverse Relaxation*: loss of signal due to B_0 inhomogeneity and the natural relaxation that would take place even in a perfectly homogeneous field. The combined effects of these two mechanisms produce a new time constant for the relaxation, which is referred to as T_2^* .

Spin-Spin Relaxation (Transverse Relaxation)

After an rf pulse, the component of M_0 in the (x, y) plane, M_{xy} , will gradually decay toward zero. The process is first order, and as it is in other types of first-order processes, the instantaneous rate of decay of M_{xy} is directly proportional to its displacement from equilibrium. The further M_{xy} is displaced from zero, the faster it decays, and as it approaches zero it decays more and more slowly. Hence, Equation 9 applies.

$$dM_{xy}/dt \propto (-M_{xy}) \quad [9]$$

The process is analogous to the decay of a radioactive element. However, spectroscopists do not speak of the rate of decay of an FID in terms of its half-life. Instead, they speak of its 1/e-life, that is, how long it takes for the FID to decay to a value that equals 1/e of its original value at time zero. Standard mathematical manipulations of Equation 9 yield

$$M_{xy} = M_0 \exp(-t/T_2^*) \quad [10]$$

where M_0 is the equilibrium distribution given by Equation 9, and T_2^* is the rate constant for the decay. T_2^* is a measure of how fast the signal decays, not how long it takes to de-

cay. The rate of decay is fastest immediately after the pulse because then it is furthest from its equilibrium position, zero. If the rate remained constant at this initial rate, then the signal would be completely decayed after one T_2^* .

Table 3 was prepared from Equation 10. It shows the percentage of M_{xy} remaining as a function of time after a 90° pulse. In Table 3 time is given as the number of T_2^* s.

M_{xy} asymptotically approaches zero, and it would take infinitely long for complete decay, but the decay is normally considered to be complete when the time has reached 3 to 5 times T_2^* . Hence, these times are commonly used as acquisition times. If acquisition times that are shorter than 3 times T_2^* are used, the FID is truncated and subsequent Fourier transform leads to visible baseline artifacts.

The decay of the FID produces the peak width in the final spectrum. The faster the decay, the broader is the line. The mathematical relationship is:

$$\Delta\nu_{1/2} = 1/(\pi T_2^*) \quad [11]$$

where $\Delta\nu_{1/2}$ is the width of the peak at its half-height.

Spin-Lattice Relaxation (Longitudinal Relaxation)

After an rf pulse, nuclei are excited from the low-energy state into the high-energy state. The nuclei will eventually relax back to establish the Boltzmann distribution (see Equation 5), and this process is called spin-lattice relaxation. The recovery process is first-order, and as it is in other types of first-order processes, the instantaneous rate of growth of M_z is directly proportional to its displacement from equilibrium. The farther M_z is displaced from M_0 , the faster it grows back, and as it approaches M_0 it grows back more and more slowly. Hence, Equation 12 applies.

$$dM_z/dt \propto (M_0 - M_z) \quad [12]$$

Standard mathematical manipulations yield

$$M_z = M_0(1 - \exp(-t/T_1)) \quad [13]$$

Note that T_1 is a measure of how fast M_z grows back to M_0 —it is not how long it takes to grow back. Table 4 was prepared from Equation 13 and shows the percentage of recovery of M_z as a function of time after a 90° pulse. In this table, time is given as the number of T_1 s.

As M_z asymptotically approaches M_0 , it takes infinitely long for 100% recovery. However, recovery is normally considered to be complete when it has reached 99%. Hence, relaxation delays of $5T_1$ are commonly used in pulse sequences. The rate of return to M_0 is fastest immediately after the pulse because that is when M_0 is farthest from its equilibrium position. If the rate remained constant at this initial rate, then full recovery would be achieved after one T_1 .

Table 3. Percent of M_{xy} Remaining as a Function of Time, in Units of T_2^*

Time/ T_2^*	0.0	0.5	1.0	1.5	2.0	3.0	4.0	5.0
% Remaining	100.0	60.7	36.8	22.3	13.5	5.0	1.8	0.7

Table 4. Percent Recovery of M_z as a Function of Time, in Units of T_1

Time/ T_1	0.0	0.5	1.0	1.5	2.0	3.0	4.0	5.0
% Recovery	0.0	39.3	63.2	77.7	86.5	95	98.2	99.3

TIP ANGLE

During an rf pulse, a magnetic field (B_1) is applied to the sample. The magnetization vector M precesses about B_1 according to

$$\omega_1 = \gamma B_1 \quad [14]$$

where ω_1 is the precessional frequency and B_1 is the strength of the magnetic field applied to the sample. During the time that the pulse is applied, M precesses to an angle (α) given by the precessional rate multiplied by the width of the pulse, in time, (PW). Then,

$$PW \times \omega_1 = \alpha = PW \times \gamma B_1 \quad [15]$$

Tip angles typically are expressed in units of degrees or in radians. For example, a 90° pulse is sometimes referred to as a $\pi/2$ pulse.

Optimum Tip Angle or Ernst Angle

Time averaging to improve the S/N ratio is accomplished by a delay-pulse-acquire sequence that is repeated as necessary. Suppose that during the first pulse, M_0 precesses 30° about B_1 before the pulse is turned off. At this time the magnitude of M_z is $M_0 \cos 30^\circ$. At the end of the pulse, M_z will begin to grow back toward its equilibrium value, M_0 . Typically, the second pulse is applied before M_z reaches M_0 , driving M_z down even farther away from M_0 . Consequently, M_z begins to grow back faster because it is even farther away from its equilibrium value. After 6–10 pulses, M_z will grow back an amount that is equal to the incremental displacement caused by each succeeding pulse and will reach a new equilibrium or steady state. Each succeeding pulse continues to tip this new steady-state value of M_z by 30° , resulting in signal intensity for each pulse.

The position of the steady-state equilibrium is determined by three factors: the T_1 , the tip angle, and the time between pulses. On the one hand, for a given T_1 and time between pulses, if the tip angle is too large then the steady-state value of M_z will be close to the origin, affording only a small signal. On the other hand, if the tip angle is too small, e.g., 5° , then the steady-state value will be large, but with a small angle the value of $M_z \sin 5^\circ$ will also be small, again affording a small signal. The optimum angle is frequently called the Ernst angle, which is given by:

$$\cos \alpha_{\text{opt}} = \exp(-PR/T_1) \quad [16]$$

$$\alpha_{\text{opt}} = \arccos[\exp(-PR/T_1)] \quad [17]$$

where PR is the time between pulses, or pulse-repetition time. This time is the sum of the acquisition time used to collect the FID plus any relaxation delay used. This angle provides a reasonably large steady-state value combined with a reasonably large angle and will produce the best S/N ratio per unit time. The value of T_1 to be used in Equation 17 should be for the longest relaxing nucleus in the molecule.

RELAXATION DELAY

Surprisingly, the optimum S/N ratio per unit time is obtained when no relaxation delay is used for a given T_1 . That is when PR equals to AT , the acquisition time. However, because the nuclei in most molecules do not have the same T_1 values, the relative intensity relationship will be lost.

For typical quantitation experiments, a relaxation delay is used and should be at least five times the longest T_1 expected for any of the nuclei in the molecule; and the pulse width should be set to 90° . Further details are provided in the section *Quantitative Applications*.

RESOLUTION

In NMR spectroscopy the typical definition of resolution is the ability to distinguish between two closely spaced resonance peaks in a spectrum. The industry standard for measuring resolution is to measure the width of a single peak, in units of Hz, at the half-height of the peak.

The uncertainty principle determines the best resolution that can be achieved in an NMR spectrum. The maximum resolution possible, or the minimum separation that can be observed between two frequencies, $\Delta\nu$, in a spectrum is equal to the reciprocal of the acquisition time, AT , of the FID.

$$\Delta\nu = 1/\Delta t = 1/AT \quad [18]$$

The time set by the spectrometer operator should not exceed the required AT , because this would result in the collection of only noise after the signal has decayed to near zero. Collecting this noise does not improve the resolution.

POSTACQUISITION DATA PROCESSING

The final appearance of the spectrum can usually be improved by applying a variety of mathematical procedures to the FID before the Fourier transform is performed. The two most common procedures are multiplying the FID by a mathematical function, generally known as a *window function*; or appending zeros to the end of the FID, generally known as *zero filling*.

Window Functions

Two types are generally used: one for increasing the resolution and another for increasing the S/N ratio.

INCREASING THE RESOLUTION

The decay of the signal produces a peak width in the spectrum, and if this decay can be removed, then the resonance peak would consist of a single point, i.e., an infinitely narrow peak. The decay of the signal can be represented by $\exp(-t/T_2^*)$. Hence the full equation representing the decaying signal is

$$A(t) = A_0 \exp(-t/T_2^*) \cos(\omega t + \theta) \quad [19]$$

If the FID is multiplied by an increasing function that exactly cancels the decay, then the peak width will be removed. This can be achieved by multiplying the FID by $\exp(t/T_2^*)$. Then Equation 19 becomes

$$A(t) = A_0 \exp(0) \cos(\omega t + \theta) = A_0 \cos(\omega t + \theta) \quad [20]$$

Unfortunately, the application of this function as described above will also disproportionately increase the noise power at the tail of the FID. The S/N ratio in the final spectrum is so poor that this function is not used without modifications. Typically, the beginning of the FID, where the S/N ratio is better, is multiplied up but then the tail of the FID, where S/N ratio is poorer, is multiplied down. Two commonly used functions that accomplish this are the Gaussian function and the transform of reversed-added FIDs (TRAF) function for resolution. The latter is sometimes given the name TRAFR by instrument manufacturers. It affords the same resolution enhancement as the Gaussian function but with much less degradation in overall S/N ratio. Numerous other window functions have been proposed though not always widely used. It should also be noted that in the quantitative experiments increasing the resolution should be used with caution because it may change the accuracy of signal integration in the spectrum.

INCREASING THE S/N RATIO

The overall S/N ratio in the spectrum can be increased by weighting the points at the beginning of the FID more highly than at the tail. This is because the S/N ratio is the highest in the beginning and the lowest at the tail. The weighting is often accomplished by multiplying the raw FID by a function that decreases with time. A popular function that gives the greatest increase in the S/N ratio is called the *matched filter*. It weights each point in the FID by an amount proportional to the S/N ratio at that point. A function that accomplishes this must match the decay. Hence, the FID is multiplied by $\exp(-t/T_2^*)$.

The penalty for the use of the matched filter is a loss of resolution that equals a doubling of the peak width. When the original decay is multiplied by the matched filter, then the new decay is given by the following:

$$\frac{\exp(-t/T_2^*) \times \exp(-t/T_2^*)}{\exp(-2t/T_2^*)} = \exp(-t/0.5T_2^*) \quad [21]$$

The FID then appears to have decayed with a T_2^* equal to one-half of the original, and according to *Equation 11* and *18* the peak width will double. Multiplying the FID by a steeper decay in an attempt to weight the beginning points more results only in less of an increase in S/N ratio and a greater increase in peak width.

Another function that accomplishes the same increase in S/N ratio, but without any change in resolution, is the TRAF function for sensitivity, which is sometimes given the name TRAFS by instrument manufacturers.

Zero Filling

Spectroscopists can improve the overall appearance of the spectrum considerably by appending zeros to the end of the FID before the Fourier transform is performed. This process results in placing more points on every resonance peak in the spectrum. The most common procedure is to append a number of zeros equal to the number used to collect the FID. Adding more zeros will result in only a very slight further improvement.

Although all of the peaks are better defined with zero filling, the resolution is not increased. For example, in a case where the separation between two lines is closer than the peak widths, only a single broadened line will result. Zero filling will not resolve these peaks—it will only place more points on an already broadened line. Only an increase in the acquisition time of the signal or the use of a window function could resolve the peaks.

Zero filling has a beneficial effect on quantitation. Integration of a digital spectrum is accomplished by taking the intensity at a given point and adding to it the intensity at successive points. If the number of data points is insufficient to depict the actual peak shape, the resultant integral of that peak will not be accurately determined. Therefore, zero filling until each peak is represented by at least 7–10 data points results in a more accurate integration. To obtain reliable peak representation and quantitative peak integration there should be at least 4–5 data points above the full width at half height of a peak.

GENERAL PROCEDURE FOR STRUCTURE IDENTIFICATION

NMR spectroscopy is a powerful technique for structure identification because of its specificity of detecting certain nuclei such as ^1H , ^{13}C , ^{31}P , and ^{19}F . Typically, a routine identification test can be performed by ^1H NMR spectroscopy in a short period of time for simple molecules. The basis for identification is provided by a comparison of the signals from the test sample with the expected signals from a qualified reference standard. A positive identification can be con-

cluded when the chemical shifts, multiplicities, and coupling constants of the spectrum of the test sample match those of the reference standard or, in the case of a *USP* monograph, the values listed in the monograph.

Data may be made unacceptable for analysis if incorrect sample preparation or poor adjustment of spectrometer parameters leads to poor resolution, decreased sensitivity, and spectral artifacts. It is preferable that the operator be familiar with the basic theory of NMR and operation of the spectrometer. Frequent checks of instrument performance are essential.

The procedures discussed here refer specifically to ^1H and ^{13}C NMR, but they are applicable, with modification, to other nuclei. The discussion assumes that the NMR spectra are obtained from solutions in suitable solvents.

Selection of Solvent

Deuterated solvents are usually used to prepare solutions for NMR analysis because they are readily available, have greatly reduced ^1H signals from solvents in ^1H spectra, and have the added advantage of providing a lock signal. Select a solvent whose residual ^1H signals will not interfere with signals of the analyte. If a residual ^1H solvent peak might interfere with any signals from the sample solution and another solvent is not possible, then the ^2H isotopic purity of the solvent should be as high as possible. Some solvents (e.g., D_2O or CD_3OD) have labile protons that can enter into fast exchange reactions with the labile protons in the analyte. This may eliminate resonance signals from $-\text{COOH}$, $-\text{OH}$, and $-\text{NH}_2$ structural groups. The most commonly used solvents for proton and carbon NMR are listed in *Table 5* along with their residual ^1H and ^{13}C chemical shifts as well as the multiplicities of these resonances caused by coupling to deuterium.

Table 5. Solvents Commonly Used for $^1\text{H}/^{13}\text{C}$ NMR Chemical Shifts

Solvent	Residual $^1\text{H}/^{13}\text{C}$ Signal ($\delta^{\text{a,b}}$) and Multiplicity	
	^1H	^{13}C
CDCl_3	7.27	77.23 (3)
CD_3OD	3.35, 4.78	49.15 (7)

^a Chemical shifts were measured at 295 K.

^b δ in ppm relative to TMS at 0 ppm.

^c Labile hydrogen.

Sample Preparation

For *USP* procedures, directions are usually given in individual monographs. The solute concentration depends on the objective of the experiment. Typically, NMR sample solutions are prepared so that they contain from a few to 50 mg/mL. Detection of minor contaminants may require higher concentrations. In some cases such as polymers, even higher concentrations can be used. The solutions are prepared in separate vials and are transferred to the NMR tube. The volume required depends on the size of the NMR tube and on the geometry of the probe. The level of the solution

Figure 4. Pulse sequence for a COSY experiment.

in the tube must be high enough to extend beyond the coils when the tube is inserted in the instrument probe.

The NMR tubes must meet narrow tolerance specifications in diameter, wall thickness, concentricity, and camber. The most widely used tubes have a 5- or 10-mm outside diameter (OD) and a length between 15 and 20 cm, but 1- and 3-mm (OD) NMR tubes are becoming more common, and tubes as large as 20 mm (OD) have been used.

Procedure

The NMR tube is placed in a probe located in the magnetic field. Although samples traditionally have been spun to average the nonradial field gradients, the quality of the shim coils no longer makes spinning a requirement, and, in the case of many 2-D experiments, the sample should not be spun. The magnetic field's homogeneity is optimized by shimming, a function that is largely being taken over by the computer in most modern spectrometers. Probe tuning is optimized for the frequency being observed and is matched to the impedance of the spectrometer.

The computer serves to control all operations of the spectrometer from running the pulse program to storing and processing the data. The experimental setup involves selecting values for a large number of variables, including the spectral width to be examined, the duration of the excitation pulse (PW), the time interval over which data will be acquired (AT), the number of transients to be accumulated, and the delay between one acquisition and the next (relaxation delay). The acquisition time for one transient is on the order of seconds. The number of transients is a function of the specimen concentration, the type of nucleus, and the objective of the experiment and can vary from a few for most ^1H experiments to several thousand for ^{13}C spectra. At the end of the experiment, the signal (FID) is stored in digitized form in the computer memory and may be displayed on the monitor. The signal can be processed mathematically to enhance either the resolution or the sensitivity, and it can be Fourier-transformed into a frequency-domain spectrum, which can be further analyzed to obtain peak positions (chemical shifts) and intensities.

Structure Elucidation by NMR

The simplest case of using NMR spectroscopy to elucidate an unknown structure is to obtain a match with a spectrum from a reference standard or from a database. The informational content of an NMR spectrum is sufficient for deduc-

ing structures of organic molecules even when qualified reference standards or spectra are not available. Relatively simple structures can be identified using chemical shifts, coupling patterns, and intensities obtained from one-dimensional (1-D) ^1H and ^{13}C spectra. For more complex structures, spectroscopists may have to obtain two-dimensional (2-D) spectra from experiments that have been developed to determine homo- or heteronuclear connectivities.

Two-dimensional spectra are characterized by two frequency axes. The intensity, which is mathematically another dimension, is not considered to be a dimension in 2-D NMR because it is not an axis that spreads out the chemical shift. All modern 2-D experiments consist of at least two pulses separated by a time period, labeled t_1 , the evolution period, and a period of time used for collecting the signals, labeled t_2 , the detection period. A CORrelation SpectroscopY (COSY) sequence is the simplest of all and is shown in Figure 4.

A series of such sequences is performed using an incremental increase in the evolution period. Fourier transforms of the FIDs produced during each of the t_2 detection periods are stacked, a second Fourier transform is performed along this t_1 new axis, resulting in a plot of amplitude along two frequency axes, F_2 and F_1 .

The next simplest addition to the COSY sequence is another pulse. The Nuclear Overhauser Effect SpectroscopY (NOESY) sequence is an example and is shown in Figure 5.

The evolution period is again the time between the first two pulses and is incremented as in the COSY experiment. The time between the second and third pulses is fixed and is not incremented. This period of time is labeled τ_m and is called the mixing time. Cross-polarization occurs during this period.

The COSY and NOESY sequences described above are the two simplest 2-D experiments to perform. Many other experiments have been developed and contain a very complicated series of pulses with different pulse widths, time delays, gated decoupling, and pulsed field gradients. Some of these experiments are described below.

Strategies for Establishment of Homonuclear Connectivities

Assigning signals based on chemical shifts, spin multiplicity, and coupling constants serves as a starting point for structural elucidation. Structure elucidation is simplified if one can establish molecular connectivity between homonuclear spins. This can be done using correlations via

Figure 5. Pulse sequence for a NOESY experiment.

bonds (scalar coupling, sometimes referred to as J coupling) or via spatial (dipolar coupling) interactions. This section describes NMR techniques that can be used for the study of homonuclear connectivity. Popular experiments in this category are COSY, total correlated spectroscopy (TOCSY), NOESY, and rotating frame Overhauser effect spectroscopy (ROESY).

COSY

COSY has become a routine 2-D ^1H NMR experiment that can quickly provide the proton–proton connectivity for spin systems connected by two or three chemical bonds. In a COSY spectrum, the contour plot typically shows diagonal and off-diagonal cross-peaks. The diagonal peaks correspond to the places in 2-D space where chemical shifts of the same nucleus in the 1-D ^1H NMR spectrum intersect. The off-diagonal cross-peaks occur in 2-D space where the chemical shift of one nucleus intersects the chemical shift of a different nucleus to which it is coupled. The COSY spectrum enables the identification of scalar-coupled spins that are in geminal or vicinal positions. Generally, one starts the assignment process by selecting a resonance in the COSY spectrum that has already been identified in the 1-D ^1H NMR spectrum. Then, the off-diagonal peaks between this resonance and any others determine the resonances of the neighboring protons to which it is coupled. The neighboring protons identified in this way then serve as the next points to examine for cross-peaks to other protons, and so forth. The process continues until all coupled spin systems are identified.

Thus, a COSY experiment can provide useful information about proton–proton connectivity for various fragments of the molecules under examination. The relationship between these fragments may be difficult to establish because of an interruption of the coupling between the two fragments. For instance, if two segments are connected through quaternary carbons or heteronuclei, the very small four-bond coupling between two protons on the two separate fragments usually cannot be detected by COSY. Basic COSY experiments are usually processed using magnitude mode, which results in broad bases to the peaks. The diagonal peaks may be so broad that spin systems with close chemical shifts may not be observable because the broadness of the diagonal peaks will cause them to overlap the off-diagonal peaks. An example of a COSY experiment, specifically a gradient, or gCOSY, is shown in Figure 6.

A variety of COSY experiments have been devised to improve upon the original experiment. Perhaps the most important change has been to use gradients to acquire a gCOSY spectrum. The classic COSY experiment uses a 90°

pulse to generate transverse magnetization and relies on elaborate phase cycling to cancel unwanted signals over many scans, resulting in long experiment times. In a gCOSY experiment, which requires a probe capable of a pulsed field gradient (PFG), a magnetic field gradient pulse dephases any coherent magnetization in the xy plane. If a second gradient pulse of the proper strength is applied in the opposite direction, it will cause any dephased double-quantum magnetization to refocus. Hence, only those signals will be received. The strengths of the gradients can be used to select single-, double- or triple-quantum coherences.

The gradient pulses in a gCOSY experiment can be used to prevent the refocusing of magnetizations that cause the artifacts in the classic COSY experiment. Hence, instead of requiring a minimum of eight phase-cycled acquisitions for each data increment in the second dimension, a gCOSY spectrum requires only a single acquisition per increment. For samples that are sufficiently concentrated to produce an acceptable S/N in only one acquisition, this greatly shortens the experimental time.

Phase-sensitive COSY experiments have been developed to overcome the problem of overlap with closely spaced chemical shifts. A phase-sensitive COSY results in pure absorptive peaks with narrower peaks than are generated by the classic-magnitude COSY. These narrower peaks allow better resolution of resonances that are close to diagonal peaks.

Double-quantum filtered COSY (DQF-COSY) was developed to overcome the problem caused by intense signals from functional groups such as methyls. The singlets from these groups do not provide useful connectivity information, but their intensity often limits the dynamic range of the experiment, making it difficult to observe other weaker signals. The pulse sequences of DQF-COSY detect the spin systems that have only double-quantum transitions. Isolated singlets are not selected and thus are filtered out of the final 2-D spectrum. In addition, a reduction in the overall intensity of the diagonal signals is achieved with an increase in the intensities of off-diagonal signals.

TOCSY (OR HOHAHA—HOMONUCLEAR HARTMANN HAHN)

The ^1H – ^1H TOCSY experiment is closely related to COSY but differs because it yields correlations for every spin in a coupled network. This is especially useful when multiplets overlap or there is extensive strong coupling. For example, consider the network $-\text{CHa}-\text{CHb}-\text{CHc}-\text{CHd}-\text{CHE}-$, where each CHn stands for a spin that is coupled through three bonds to the adjacent spin. A COSY spectrum would show correlations for each adjacent pair of hydrogens. On the one hand, the Hb resonance would show connectivities to Ha

Figure 6. Partial COSY spectrum of sucrose. Dotted lines show how two off-diagonal (f3, f4 and g2, g3) contours are used to determine which nuclei are coupled to each other.

and Hc but not to Hd. A partial correlation is revealed for each CHn. On the other hand, a TOCSY spectrum would show all off-diagonal contours for every spin in this network. That is, for every peak in this coupling network there would be off-diagonal contours corresponding to CHa, CHb, CHc, CHd, and CHe. Thus, a TOCSY spectrum, such as the one shown in Figure 7, affirmatively identifies all of the spins within the same coupling network. This pattern is easily recognized, especially when there is extensive overlap with other coupled networks. However, a TOCSY experiment cannot establish connectivity between separate networks that are interrupted by heteronuclear atoms, quaternary carbons, or a carbon bearing only exchangeable protons. A TOCSY experiment is useful for the study of large molecules with many separated coupling networks such as peptides, proteins, oligosaccharides, and polysaccharides.

NOESY

The NOESY experiment gives correlations between protons that are close to each other in space even though they may not be connected by bonds. These through-space correlations are made via spin-lattice relaxation. Dipole interactions between protons close in space generate NOE transfers, and the magnetization is aligned along the z axis (B_0), producing positive or negative intensity changes that yield cross-peaks that are not normally observable in a COSY spectrum. The sign of the NOESY peaks depends on the size and mobility of the molecule under study. Used in combination with other techniques, a NOESY experiment can establish spatial relations for particular spins and can provide critical information about ring structures and conformations.

^1H – ^1H ROESY

The ROESY experiment is similar to a NOESY experiment insofar as it also provides correlations between protons that are close to each other in space, whether or not they are connected via bonds. A ROESY spectrum yields through-space correlations via spin-spin relaxation in the rotating frame. The ROESY experiment utilizes a spin-lock sequence as a mixing time during which NOE transfer occurs among

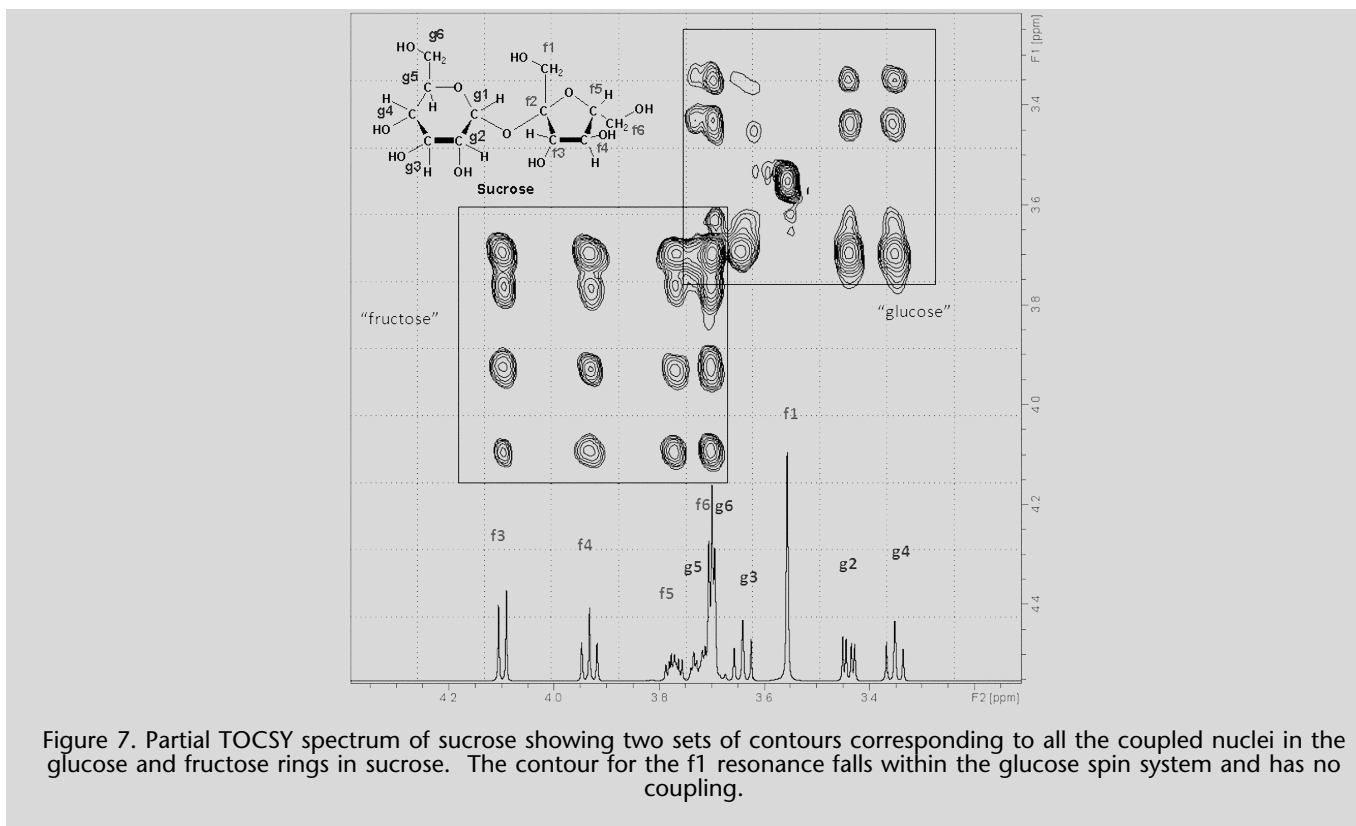

all components of the spins locked in the xy plane. In contrast to a NOESY experiment, in which NOE transfer occurs while magnetizations are aligned along the z axis (B_0) producing positive or negative intensity changes, the ROESY experiment depends on NOE transfers occurring in the rotating frame under the influence of a B_1 magnetic field. This always results in positive signals no matter how large the molecule or whether its motion is fast or slow. Therefore, a ROESY experiment frequently will provide through-space correlations when the same correlations in a NOESY experiment cannot be detected because of molecule mobility.

INCREDIBLE NATURAL ABUNDANCE DOUBLE QUANTUM TRANSFER EXPERIMENT

The Incredible Natural Abundance Double Quantum Transfer Experiment (INADEQUATE) uses a double quantum coherence to provide information about ^{13}C nuclei directly coupled to other ^{13}C nuclei. Thus it provides the same sort of information that is available using a COSY experiment for proton couplings. Because of the low probability of two ^{13}C nuclei being attached to each other (only 1 in 10,000 molecules), this technique is usually one of last resort. The ever-increasing sensitivity of cryogenically cooled probes used in modern instrumentation makes this experiment practical in some cases.

Strategies for Establishment of Heteronuclear Connectivities

Although homonuclear ^1H – ^1H connectivity is one important aspect of structure elucidation of organic molecules, the establishment of heteronuclear connectivities is equally important, although somewhat more difficult to obtain given the lower abundance of most heteroatoms. If one has partial assignments in either the ^1H or ^{13}C spectrum, the knowledge of this connectivity leads to a much fuller assignment of both spectra. Heteronuclear 2-D spectra do not exhibit a diagonal as is seen in homonuclear correlations. Rather, cross-peaks occur at the point of intersection of the

^1H and ^{13}C chemical shifts in the 2-D space as shown in Figure 8.

Heteronuclear 2-D spectra are designed so that ^1H is the detected nucleus and are usually acquired using inverse-

detection probes because the ^1H coil is wound closer to the sample than the broadband coil. This results in a better filling factor and a greater sensitivity for the ^1H coil. It should be noted that a newer configuration of coils has been devel-

oped that provides the same sensitivity but does not utilize the inverse-detection coil arrangement. Typical heteronuclear 2-D experiments include Heteronuclear Single Quantum Coherence (HSQC), Heteronuclear Multiple Quantum Coherence (HMQC), and Heteronuclear Multiple Bond Correlation (HMBC) experiments.

HMQC

The 2-D HMQC experiment provides information about correlation between protons and their attached heteronuclei via the heteronuclear scalar coupling. The sequence selects double quantum coherence transfer between scalar-coupled spins (^{13}C - ^1H).

HSQC

HSQC spectroscopy is also an inverse chemical shift correlation experiment that yields the same information as HMQC, i.e., the identification of directly bonded hydrogen-carbon interactions. The correlation between heteronuclei is detected via the selection of single quantum coherence transfer using the insensitive nuclear enhancement by polarization transfer (INEPT) sequences. The main advantage of using this sequence instead of the HMQC sequence is that the F_1 domain does not contain any proton-proton couplings. Hence, the resolution is improved.

An interesting modification of this sequence is an edited HSQC experiment. This is a phase-sensitive experiment that not only gives one-bond correlations between hydrogen and carbon but also gives methyl and methine correlation peaks that are 180° out of phase with methylene resonances.

HMBC

HMBC spectroscopy is a modified version of HSQC and is suitable for determining long-range (> 1 -bond) ^1H - ^{13}C connectivity. Long-range heteronuclear correlation spectroscopy can yield signals for those nuclei that are separated by 2-4 bonds. This experiment, in conjunction with the other 2-D experiments discussed above, allows one to define the structure of a molecule in great detail.

QUANTITATIVE APPLICATIONS

NMR is one of the most useful techniques for quantitative analysis in chemistry. If appropriate experimental conditions are chosen, the relative intensities of resonances are proportional to the population of the nuclei causing those resonances. NMR experiments can be designed for relative or absolute quantitation, either with an internal standard or without one.

Experimental Design for Quantitative NMR

Design for quantitation involves the elimination or precise measurement of differences in intensities due to spin-lattice relaxation and NOE. The spin-lattice relaxation time (T_1) for all resonances used in the procedure can be measured with an inversion recovery pulse sequence. If a 90° pulse is used for excitation, quantitation at the level of 99.3% may be achieved with a recycle time, T_r (the sum of the relaxation delay and acquisition time), of $5 \times T_1$, and improved to even higher levels by using longer recycle times or shorter pulses. The general equation for the degree of quantitation, Q , of a resonance as a function of the pulse angle, α , and T_r , and T_1 is given by:

$$Q = \frac{1 - e^{-T_r/T_1}}{1 - [e^{-T_r/T_1} \cdot \cos(\alpha)]} \quad [22]$$

If a 45° excitation pulse is used, with a $T_r = 5T_1$, $Q = 0.998$. However, the accuracy of quantitation in the final spectrum depends not only on the Q values of the resonances but also on the accuracy of the integration method and on the S/N ratio in the spectrum. Hence, Q values somewhat less than unity may be warranted and other angles and recycle times should be used.

The minimization of systematic quantitation bias should be sufficient for the intended use of the procedure. Alternatively, quantitative procedures may be developed using conditions for which Q is not unity for some or all resonances, provided the value of Q is precisely known and corrected for.

For quantitative methods using heteronuclei, the possibility of differential NOEs should be avoided by using a T_r at least 5 times the longest T_1 value and by using inverse gated decoupling (decoupler gated on only during the acquisition time). Preferably, 90° pulses should be used. For quantitative methods, relaxation agents are often used for shortening the T_1 values of heteronuclei.

The reproducibility of an NMR method depends on a variety of acquisition and processing parameters, all of which should be described in the procedure. These include pulse angle, acquisition time, relaxation delay, spectral width, number of points in the FID, number of acquisitions, number of points used (if any) for zero filling, line broadening, baseline correction, integral breaks, and temperature. For best reproducibility, integral breaks should be specified to 0.01 ppm for ^1H NMR methods and to 0.1 ppm for ^{13}C methods.

Quantitative analysis, as well as detection of trace impurities, has markedly improved with modern instrumentation. Stronger magnetic fields and improved probe technology have enhanced the sensitivity of NMR procedures in recent years.

SOLID-STATE NMR

The analytical usefulness of solid-state NMR spectroscopy for studying solid materials lies in the fact that the same types of nuclei in different *solid-state* environments exhibit different resonance frequencies. Applications of this technique in pharmaceutical analysis range from solid form (polymorph, solvate) identification and quantitation in bulk drug substances to physical/chemical profiling of dosage forms. The technique has the unique ability to probe electronic environments of specific nuclei in the solid state over a large timescale without the requirement of single-crystal substrates or even homogeneous samples. Methods and procedures presented herein are directed at observing ^{13}C , the most popular NMR nucleus for solids. The concepts may be equally applied to other relevant spin-1/2 nuclei such as low-natural-abundance ^{15}N as well as high-natural-abundance ^{31}P .

Cross-Polarization Magic Angle Spinning (CPMAS) NMR Technique

The basic principles of NMR are the same for solution and solid-state measurements, but conventional solution-phase 1-D NMR data acquisition techniques do not normally produce detectable spectra for solid samples because of low sensitivity and extensive line broadening. The sensitivity of the solid-state experiment is low for ^{13}C based on its 1.1% natural abundance and long spin-lattice (T_1) relaxation times. Line broadening arises primarily from dipole-dipole interactions and chemical shift anisotropy (CSA), which are not averaged to zero because of the fixed orientation of molecules in a packed solid sample vs the rapid molecular

Figure 9. ^{13}C CPMAS NMR spectra of polycrystalline α -glycine collected at different sample spinning (MAS) rates. Spinning sidebands appear in solid-state NMR spectra when the sample spinning frequency is less than the width of the CSA pattern.

tumbling of the molecules when they are in solution. If not averaged, CSA results in the simultaneous observation of all different orientations of molecules with respect to the applied magnetic field. CSA patterns may span the width of an entire liquid spectrum. Three modifications to standard solution methods—cross-polarization (CP), magic angle spinning (MAS), and high-power ^1H decoupling—are routinely used in combination to obtain high-resolution solid-state NMR spectra.

CROSS-POLARIZATION (CP)

CP addresses the low sensitivity associated with collecting NMR spectra of dilute spin-1/2 nuclei such as ^{13}C . CP is a double-resonance procedure wherein abundant ^1H and rare ^{13}C spins are brought into resonance by simultaneously applying two spin-locking rf fields ($B_{1\text{H}}$ and $B_{1\text{C}}$), the magnitude of which will satisfy the Hartmann–Hahn matching condition,

$$\gamma_{\text{H}}B_{1\text{H}} = \gamma_{\text{C}}B_{1\text{C}} \quad [23]$$

During this contact time, polarization transfer occurs allowing the rare ^{13}C spins to take on the magnetization and relaxation behavior of the abundant ^1H spins, leading to a sensitivity enhancement (up to four-fold based on the ratio of the ^1H and ^{13}C magnetogyric ratios) and a reduction in the pulse repetition time. Reducing the pulse repetition time allows a greater number of acquisitions to be accumulated per unit time, which yields a better S/N ratio. In instances where it may be difficult or impossible to record CP spectra because of weak ^{13}C – ^1H coupling or short spin-lattice relaxation times in the rotating frame ($T_{1\rho\text{H}}$), direct polarization (Bloch decay) may be the only approach to recording solid-state NMR spectra.

MAGIC ANGLE SPINNING (MAS)

Line broadening in solid-state NMR is eliminated or averaged by both MAS and high-power ^1H decoupling. MAS involves mechanically rotating the sample at an angle of 54.7° (the magic angle) relative to the static magnetic field in order to simulate rapid molecular tumbling in solution. Rotating a solid sample at the magic angle to minimize line broadening requires that the sample be spun faster (in Hz) than the width of the CSA. High spinning rates are possible

with current MAS probe technology, but complications can arise with CP and may require techniques such as ramped-amplitude CP (RAMP-CP) and variable-amplitude CP (VACP) to improve the efficiency of magnetization transfer from ^1H . Additionally, MAS can raise the sample temperature significantly if it is not controlled, and pressures at the periphery of the rotor may be thousands of times the ambient pressure. These stresses may induce phase transformations, loss of solvent, and other effects.

SIDEBAND SUPPRESSION

As shown in Figure 9, slower spinning rates can be used to avoid compromising the solid sample, but when CSA is incompletely averaged, spinning sidebands will appear in solid-state NMR spectra. These artifacts are separated from the centerbands by integer multiples of the spinning rate (in Hz) and can be readily identified as the peaks that shift in spectra acquired at different spinning speeds. Spinning sideband manifolds contain useful information but can interfere with the signals of interest and may be particularly problematic when one uses higher field instruments. The total suppression of spinning sidebands (TOSS) procedure is commonly used to eliminate spinning sidebands from solid-state NMR spectra.

HIGH-POWER ^1H DECOUPLING

High-power ^1H decoupling is used to further reduce the line broadening from dipolar coupling to ^1H spins in the solid state. Specialized hardware is required to deliver the rf power needed for ^1H decoupling in solids, an rf power that is two orders of magnitude greater than that required to remove scalar coupling in liquids. CW decoupling is commonly used in solid-state NMR, although two-pulse phase-modulated and small phase incremental alteration (SPINAL-64) decoupling are increasingly used to improve the sensitivity and resolution of dilute spin spectra.

Typically only ^1H – ^{13}C heteronuclear dipolar interactions are significant when one acquires solid-state ^{13}C NMR spectra of organic materials. Homonuclear ^{13}C – ^{13}C dipole–dipole and scalar coupling interactions are negligible. Because of their low natural abundance, the probability that two ^{13}C nuclei are in close proximity is very small. However, homonuclear ^{13}C – ^{13}C dipolar coupling can be a concern for ^{13}C -labeled substrates.

EXPERIMENTAL SETUP

The basic setup for a CPMAS experiment will necessarily include magic angle setting, shimming, pulse calibration, Hartmann–Hahn matching, and spectral referencing, each of which is typically conducted on standard samples. Accurate measurement of the pulse lengths and associated rf power levels is essential for solid-state NMR experiments. Setting up the magic angle, shimming a CPMAS probe, and measuring its sensitivity for different tuning ranges are parts of probe setup and performance assessment. Shimming a solid-state NMR probe for MAS is more complicated than that for a solution probe because shim gradients are designed for the vertical orientation of solution NMR tubes. Solid-state NMR probes have no ²H lock channel, so shimming must be performed manually. Because of the intrinsically broad peaks, shimming is not nearly as critical in solid-state NMR as it is in solution NMR.

Standard compounds used for setting the magic angle and optimizing pulse lengths and the associated rf power levels for CP are listed in Table 6. KBr is commonly used for magic angle adjustments, observing the ⁷⁹Br resonance and adjusting the sample spinning angle to maximize (to 10 ms and beyond) the duration of the rotational echo train in the FID. Liquid samples can be used to shim solid-state NMR probes, although solid adamantane is commonly used for this purpose. Adamantane, glycine, and hexamethylbenzene (HMB) are commonly used for Hartmann–Hahn matching and testing sensitivity. Typically, the reference sample for testing sensitivity is permanently packed into a rotor to ensure that the same amount of sample is used.

Solid-state NMR spectrometers are generally used without field/frequency locking, so the resulting chemical shifts are less accurate than those for solutions. Calibration of the chemical shift can be done using either a primary or secondary standard. Spectral referencing is typically performed by sample replacement (external referencing). Standard compounds commonly used for spectral referencing in solid-state NMR are listed in Table 7. Note that glycine is polymorphic, so its crystal form should be ensured before its use in referencing spectra.

General Test Procedure

Spectrometer performance should be demonstrated first for a reference sample as described in *Cross-Polarization Magic Angle Spinning (CPMAS) NMR Technique, Experimental*

Setup. The magic angle, pulse lengths, and associated rf power levels for CP that are established using the reference compounds are sample independent. To obtain a CP spectrum of the sample, only the recycle delay needs to be chosen, followed by the contact time. When quantitative signal intensities are not required, an optimum recycle delay, i.e., one that affords the best S/N ratio, is 1.2*T*_{1H}, and the contact time is generally that which provides the optimum S/N ratio or that which best shows the features of most interest. For quantitative CP, a recycle delay of at least five times the longest *T*_{1H} of a heterogeneous mixture is suggested to ensure full relaxation, and a full analysis of the CP signal as a function of contact time must be conducted. See the subsection *Quantitative Analysis*.

SAMPLE PREPARATION

Sample-handling procedures used in solid-state NMR are substantially different from those used in liquid NMR. Solid samples are packed in ceramic rotors that are capped with fluted drive tips specifically designed for MAS. Fine powders are typically tamped into MAS rotors, although solid plugs, e.g., whole tablets, can be cut to fit the exact inner dimensions of the rotor and can be inserted directly into the rotor. Crushing or grinding may be used to reduce the sample to a fine powder, but caution should be used in order not to induce phase transformations. Depending on the compressibility of the powder and the rotor volume, 40–400 mg of material is typically required to fill a sample rotor.

Physical Characterization

Specific components in heterogeneous systems can be searched based on unique nuclei or different NMR relaxation properties. The identification of crystalline and amorphous materials can be accomplished by comparison of the solid-state NMR spectrum of the sample preparation with that of a reference standard. Chemical shifts and relative peak intensities can be used in the comparison. Amorphous materials generally give good MAS spectra with broader peaks than those seen for crystalline materials. Highly crystalline samples typically give ¹³C linewidths of the order of a few tens of Hz. The shape of the signals generally is between Lorentzian and Gaussian, a fact that should be recognized in deconvoluting overlapped spectra.

Table 6. Standard Samples Commonly Used for Setting Up CPMAS Experiments

Setup Procedure	Nucleus	Standard Sample(s)
Setting the magic angle	⁷⁹ Br	KBr
Shimming	¹³ C	adamantane
Pulse calibration	¹ H, ¹³ C	adamantane, HMB
Hartmann-Hahn matching	¹ H/ ¹³ C	adamantane, HMB
Sensitivity	¹³ C	HMB, adamantane, α-glycine

Table 7. Reference Compounds Commonly Used for Solid-State NMR

Nucleus	Primary Standard	Secondary Standard(s)	Chemical Shift in ppm from Primary Standard
¹³ C	TMS	HMB adamantane α-glycine	17.35 (CH ₃) 38.48 (CH ₂) 176.45 (carboxyl)
¹⁵ N	nitromethane	NH ₄ ¹⁵ NO ₃ ¹⁵ NH ₄ Cl α-glycine- ¹⁵ N	–5.1 (NO ₃) –338.1 –349.5
³¹ P	85% H ₃ PO ₄	CaHPO ₄ · 2H ₂ O (brushite)	1.4
²⁹ Si	TMS	tetramethylsilylmethane	–1.4
¹⁹ F	CF ₃ Cl	perfluorobenzene	–166.4

Relaxation

Relaxation parameters of interest in solids include spin-lattice relaxation (T_1), spin-lattice relaxation in the rotating frame ($T_{1\rho}$), spin-spin relaxation (T_2), and cross-relaxation (T_{CP}). In organic solids, ^1H spin diffusion is generally efficient so that pure compounds normally give single values for each of the relaxation times, T_1 and $T_{1\rho}$. For CP experiments, T_{1H} is used to establish the recycle delay between acquisitions. T_{1H} relaxation times can be measured using either progressive saturation or inversion recovery pulse sequences. In CP experiments, T_{CP} and $T_{1\rho H}$ characterize the magnetization build-up and decay, respectively. $T_{1\rho H}$ is measured via the ^{13}C signal using a delayed contact CP pulse sequence that has a variable delay time before the CP contact.

Quantitative Analysis

To quantitatively assess solid-state NMR spectra under CP conditions, extra measures must be taken. In addition to ensuring that the sample spinning axis is precisely set to the magic angle (54.7°) to minimize CSA broadening, the temperature and spin rate must be carefully controlled and the MAS probe properly tuned. Suggested recycle delays of $5T_{1H}$ are allotted between successive pulses to ensure that the magnetization has returned to its full equilibrium value. Both T_{CP} and $T_{1\rho H}$ relaxation must then be accounted for in the selection of the contact time. Typically, the CP contact time chosen is that which provides maximum sensitivity for the signals of interest. Quantitative analysis can be performed using either internal or external referencing methods. The use of internal standards can compensate for variability in sample volume and B_1 inhomogeneity throughout the sample.

By properly setting data acquisition parameters (recycle time, pulse widths, contact time, Hartmann–Hahn match, and decoupling power for each chemical system), signals can be obtained that are proportional to the number of nuclei producing them. For quantitative analysis, integrated signal intensities should be used rather than peak heights because linewidths in solid-state spectra often vary. When spinning sidebands are not eliminated by MAS, the intensity of the spinning sideband manifold must be added to the centerband intensity.

Spectral Editing

A key step in the analysis of any NMR spectrum is the assignment of individual resonances to unique phases and, in some cases, to specific atoms in the molecule. Special pulse sequences are available and may assist in simplifying CP/MAS spectra and assigning signals. Dipolar dephasing, also known as nonquaternary suppression or interrupted decoupling, yields spectra that typically contain signals only from quaternary and methyl carbons. Spectral subtraction of dipolar dephasing spectra from normal CP spectra or short contact time CP may be used to produce subspectra that contain signals from methylene and methine carbons only. Polarization-inversion techniques can be used to identify methylene and methine carbons.

LOW-FIELD NMR

Low field NMR (LF-NMR), sometimes referred to as time domain NMR (TD-NMR), experiments are performed by measuring relaxation, relaxometry, or diffusion. Instrumentation for these applications is based on low-field permanent magnet technologies that operate in the 2–25 MHz frequency range. Inexpensive stationary bench-top and portable TD-NMR spectrometers are commercially available. Typical bore sizes are 10–50 mm in diameter. A recent

development in spectrometer design uses a mobile mouse probe as an alternative to a stationary magnet. This design allows analysis of samples of unrestricted size.

Most TD-NMR applications are based on simple pulsing sequences, including FID, Hahn–echo, Carr–Purcell–Meiboom–Gill, and solid–echo acquisition. The choice of pulse sequence depends on the physical and chemical properties of the sample as well as the information that is desired from the experiment. These systems can be used to measure longitudinal (spin-lattice, T_1) and transverse (spin-spin, T_2) relaxation times. Diffusion properties of compounds can be exploited using pulsed field gradient (PFG-NMR) experiments.

The classical application of relaxometry is for the determination of food product components based on differences in longitudinal and transverse relaxation times of water, fats, and proteins.

Relaxivity

The magnitude of a substance's capacity to enhance the relaxation rate of a nucleus is referred to as relaxivity, expressed in units of $\text{sec}^{-1}\text{mM}^{-1}$. An example of such a substance commonly used in NMR spectroscopy is paramagnetic chromium acetylacetonate. Paramagnetic species are used in the medical industry as contrasting agents for magnetic resonance imaging. The relaxivity of a substance is determined experimentally by measuring the spin-lattice relaxation time (T_1) of a test substance and plotting $1/T_1$ against the concentration in units of mM (mmol/L). The slope of the curve is the numerical relaxivity. ▲ USP36

(1788) METHODS FOR THE DETERMINATION OF PARTICULATE MATTER IN INJECTIONS AND OPHTHALMIC SOLUTIONS

Methodology for the determination of particulate matter in injections is contained in USP (788), which has been harmonized with the European Pharmacopoeia and the Japanese Pharmacopoeia. Sections on instrument standardization for light obscuration and other method details were excluded from the harmonized chapter. Chapter (789) *Particulate Matter in Ophthalmic Solutions* has not been harmonized. Chapter (1788) includes important instrument standardization and calibration information applicable to (788) and (789); it also includes recommendations for sample handling, laboratory environment, operator training and general advice applicable to the microscopic method.

Chapter 1 requires injections to be essentially free from particulate matter that can be observed on visual inspection. The term “essentially free” has been difficult to define because particle detectability is influenced by their number and size, among other factors. The absolute limit of visibility, or detectability, is equivocal and depends upon the test conditions and the nature of the particulate matter. The lower end of the visible range certainly crosses over sub-visible detection capabilities in (788) and (789). Literature reports visibility extending to 50 μm , 100 μm , and 150 μm size (see *References 1 and 2*), and membrane assay can isolate and size particles to 1000 μm and larger.

Chapter (788) specifies limits for the sub-visible particulate matter content in injections in two size thresholds. Likewise, Chapter (789) establishes particle content expectations for ophthalmic solutions in two (Light Obscuration, or LO) or three (Membrane Microscope, or MM) size thresholds. The tests described in (788) and (789) are physical limit tests performed for the purpose of enumerating sub-visible particles [particulate matter] within specific size ranges (see Figure 1).

Chapter (788) states, "Particulate matter consists of mobile undissolved particles, other than gas bubbles, unintentionally present in the solutions." Using the (788) test methods, any semi-solid to solid material (and even immiscible liquids) that trigger LO detector response above a selected size threshold will be tabulated.

There are two general categories of particulate matter sources: extrinsic and intrinsic. LO and MM methods will detect and tabulate particles of both categories. Extrinsic material is additive, foreign, and unchanging, and not part of the formulation, package, or assembly process.

Examples of extrinsic material include fibers, cellulosic matter, vegetative matter, corrosion products, paint/coatings, and building materials such as gypsum, concrete, metal, and plastic. Extrinsic particles are additive and generally non-changing over the life of the product, unless by fragmentation, swelling (hydration), or degradation. Fragments of rubber, plastic, metal, and glass are examples of extrinsic particulate matter deposited in the product during assembly or not removed in the container preparation process. However, if these typically extrinsic types have come from the specific package and/or process in a more consistent or chronic manner, then one may consider their presence to be an intrinsic variety, with a similar level of concern.

Intrinsic material is associated with the package, formulation ingredients and process or assembly process. Intrinsic material may also be extraneous material carried by the package or process and insufficiently removed. Intrinsic material may indeed change upon aging, due to concentration change, degradation, and acceleration of reaction.

Intrinsic sources are inherent in the product and process—formulation, package, and commercial assembly steps. Intrinsic sources represent a variety of phenomena yielding unwanted substances, such as: (a) extraction, (b) leaching, (c) degradation of ingredient (active or excipient), (d) change of ingredient by precipitation/salt form/crystalline form, (e) change of package physical integrity, (f) change of impurity level, (g) change of micellar association, (h) oligamerization, and (i) package- and process-related materials not removed during product assembly. Combinations of all of the above and physical phenomena such as aggregation, sedimentation, and coalescence by matrix (oils, semi-solids) may bring smaller particles ($<10\ \mu\text{m}$) into the detection zone of the test method ($\geq 10\ \mu\text{m}$). Intrinsic sources of detectable particulate matter are of great concern, since the substance may be present, however, not evident until particles form over time, even long after lot release.

The intrinsic categorization should be recognized as different from inherent formulation character. Solution properties such as a slight haze or faint coloration of high concentration formulae and protein formulations are typical examples of an inherent characteristic of the product fluid, and while the condition may cause difficulties in inspection or LO assay, are not particle-related.

Certain solution formulations may not be easily analyzed by LO. The LO method may encounter problems with a product that does not have clarity and a viscosity approximating those of water. Further, formulation characteristics such as color, high viscosity or inherent formulation properties, such as shear-induced changes, may generate erroneous LO data. Similarly, products that produce air or gas bubbles when drawn into the LO sensor, such as bicarbonate-buffered formulations may generate erroneous data. For these product types the MM method may have to be used. Documentation demonstrating that the LO procedure

is incapable of testing the test article or produces invalid results may aid regulatory filing strategy. It is expected that most test articles will meet the requirements on the basis of the LO test alone; however, it may be necessary to assay some test articles by the LO method followed by the MM method in order to reach a conclusion.

There may be a desire to test lower volumes of certain products, due to limited sample, high product cost, low container volume, or due to special fluid delivery characteristics. Examples include biopharmaceuticals, low-volume parenteral and ophthalmic products and formulations in novel packages intended for specific medical targets. The expectation is limits compliance for these products; however, one may employ methods validated by the manufacturer to demonstrate conformance with the test limits. Special low-volume "sippers" for LO sampling and the pooling of multiple containers may be necessary for these package presentations. Consider this example: a low-volume ($100\ \mu\text{L}$) product is packaged in a pre-filled sterile syringe. The nature of the package allows simple delivery of the solution product and may be used for direct sampling, but the $100\ \mu\text{L}$ volume precludes the pooling of the larger volumes ($\sim 25\ \text{mL}$) for the LO method. Direct sampling to a small membrane for microscopical counting and evaluating single and pooled package particle content may be the optimal means to collect data. Also in this example, careful statistical evaluation of the batch population using small sample volumes (but not doses) will be necessary to validate product acceptability.

Size domains considered in USP <1>, <788>, <789>

Figure 1. Increasing Probability of Visual Detection.

LIGHT OBSCURATION PARTICLE COUNT TEST

Test Apparatus

The apparatus is a liquid-borne particle counting system that uses a light-obscuration sensor with a suitable sample-feeding device to deliver controlled aliquots of sample for analysis. Suspended particles in the sample fluid flowing between a light source and sensor produce changes in signal that are correlated to particle dimension. Due to the nature of the detection and counting system, air bubbles and immiscible liquids may block sufficient light to be recorded along with the target suspended particles. These artifacts must be diminished through proper preparation techniques. Solutions with excessive immiscible liquids may not be amenable to LO analysis. A variety of suitable devices of this type are commercially available. It is the responsibility of those performing the test to ensure that the operating parameters of the instrumentation are appropriate to the required accuracy and precision of the test result, the artifacts and interferences inherent in certain products and with certain methods of preparation are eliminated or accommodated. An example is a protein formulation that may form shear-induced semi-solids due to mixing and counted as "particles." Adequate training must be provided for those responsible for the technical performance of the test.

It is important to note that for Pharmacopeial applications the ultimate goal is that the particle counter reproducibly size and count particles present in the material under investigation. The instruments available range from systems where calibration and other components of standardization must be carried out by manual procedures to sophisticated systems incorporating hardware- and software-based functions for the standardization procedures. Thus, it is not possible to specify exact methods to be followed for standardization of the instrument, and it is necessary to emphasize the required end result of a standardization procedure rather than a specific method for obtaining this result. This section is intended to emphasize the criteria that must be met by a system rather than specific methods to be used in their determination. It is the responsibility of the user to apply the various methods of standardization applicable to a specific instrument. Critical operational criteria consist of the following.

Sensor Concentration Limits—Use an instrument that has a concentration limit (the maximum number of particles per mL) identified by the manufacturer that is greater than the concentration of particles in the test specimen to be counted. The vendor-certified concentration limit for a sensor is specified as that count level at which coincidence counts due to the simultaneous presence of two or more particles in the sensor view volume compose less than 10% of the counts collected for 10- μ m particles.

Sensor Dynamic Range—The dynamic range of the instrument used (range of sizes of particles that can be accurately sized and counted) must include the smallest particle size to be enumerated in the products.

Instrument Standardization Tests

The following discussion of instrument standardization emphasizes performance criteria rather than specific methods for calibrating or standardizing a given instrument system. This approach is particularly evident in the description of calibration, where allowance must be made for manual methods as well as those based on firmware, software, or the use of electronic testing instruments. Appropriate instrument qualification is essential to performance of the test according to requirements. Since different brands of instruments may be used in the test, the user is responsible for ensuring that the counter used is operated according to the manufacturer's specific instruction; the principles to be followed to ensure that instruments operate within acceptable ranges are defined below. The following information for instrument standardization helps ensure that the sample volume accuracy, sample flow rate, particle size response curve, sensor resolution, and count accuracy are appropriate to performance of the test. Conduct these procedures at intervals of not more than six months.

SAMPLE VOLUME ACCURACY

Since the particle count from a sample aliquot varies directly with the volume of fluid sampled, it is important that the sampling accuracy is known to be within a certain range. For a sample volume determination, determine the dead (tare) volume in the sample feeder with particle-free water.¹ Transfer a volume of particle-free water that is greater than the sample volume to a container, and weigh. Using the sample feeding device, withdraw a volume that is appropriate for the specific sampler, and again weigh the container. Determine the sample volume by subtracting the tare volume from the combined sample plus tare volumes. Verify that the value obtained is within 5% of the appropriate sample volume for the test. Alternatively, the sample volume may be determined using a suitable Class A graduated cylinder (see *Volumetric Apparatus* (31)). [NOTE—Instru-

ments of this type require a variable tare volume. This is the amount of sample withdrawn before counting. This volume may be determined for syringe-operated samplers by setting the sample volume to zero and initiating sampling, so that the only volume of solution drawn is the tare. Subtract the tare volume from the total volume of solution drawn in the sampling cycle to determine the sample volume.]

SAMPLE FLOW RATE

Verify that the flow rate is within the manufacturer's specifications for the sensor used. This may be accomplished by using a calibrated stopwatch to measure the time required for the instrument to withdraw and count a specific sample volume (i.e., the time between beginning and ending of the count cycle as denoted by instrument indicator lights or other means). Sensors may be operated accurately over a range of flow rates. Perform the *Test Procedure* below at the same flow rate as that selected for calibration of the instrument.

CALIBRATION

USP (788) specifies the use of dispersions of spherical particles of known sizes between 10 μ m and 25 μ m in particle-free water. More options follow:

Manual Method—Calibrate the instrument with a minimum of three calibrators, such as near-mono-size polystyrene spheres having diameters of about 10, 15, and 25 μ m, in an aqueous particle-free vehicle. The calibrator spheres must have a mean diameter of within 5% of the nominal diameters and be standardized against materials traceable to NIST standard reference materials.² The total number of spheres counted must be within the sensor's concentration limit. Prepare suspensions of the calibrator spheres in water at a concentration of 1000 to 5000 particles per mL, and determine the channel setting that corresponds to the highest count setting for the sphere distribution. This is determined by using the highest count threshold setting to split the distribution into two bins containing equal numbers of counts, with the instrument set in the differential count mode (moving window half-count method). Use only the central portion of the distribution in this calculation to avoid including asymmetrical portions of the peak. The portion of the distribution, which must be divided equally, is the count window. The window is bounded by threshold settings that will define a threshold voltage window of $\pm 20\%$ around the mean diameter of the test spheres. The window is intended to include all single spheres, taking into account the standard deviation of the spheres and the sensor resolution, while excluding noise and aggregates of spheres. The value of 20% was chosen on the basis of the worst-case sensor resolution of 10% and the worst-case standard deviation of the spheres of 10%. Since the thresholds are proportional to the cross-sectional area of the spheres (and all particles) rather than the diameter, the lower and upper voltage settings are determined by the equations:

$$V_L = 0.64V_S$$

in which V_L is the lower voltage setting, and V_S is the voltage at the peak center, and

$$V_U = 1.44V_S$$

in which V_U is the upper voltage setting. Once the center peak thresholds are determined, use these thresholds for the standards to create a regression of log voltage versus log particle size, from which the instrument settings for the 10- and 25- μ m sizes can be determined.

² ASTM standard F658-00a provides useful discussions pertaining to calibration procedures applying near-monosize latex spheres.

¹ Passed through a filter having a nominal pore size of 1.2 μ m or finer.

Automated Method—The calibration (size response) curve may be determined for the instrument-sensor system by the use of validated software routines offered by instrument vendors; these may be included as part of the instrument software or used in conjunction with a microcomputer interfaced to the counter. The use of these automated methods is appropriate if the vendor supplies written certification that the software provides a response curve equivalent to that attained by the manual method and if the automated calibration is validated as necessary by the user.

Electronic Method—Using a multichannel peak height analyzer, determine the center channel of the particle counter pulse response for each standard suspension. This peak voltage setting becomes the threshold used for calculation of the voltage response curve for the instrument. The standard suspensions used for the calibration are run in order, and median pulse voltages for each are determined. These thresholds are then used to generate the size response curve manually or via software routines. The thresholds determined from the multichannel analyzer data are then transferred to the counter to complete the calibration.

SENSOR RESOLUTION

The particle size resolution of the instrumental particle counter is dependent upon the sensor used and may vary with individual sensors of the same model. Determine the resolution of the particle counter for 10- μ m particles, using the 10- μ m calibrator spheres. The relative standard deviation of the size distribution of the standard particles used is not more than 5%. Acceptable methods of determining particle size resolution are (1) manual determination of the amount of peak broadening due to instrument response; (2) using an electronic method of measuring and sorting particle sensor voltage output with a multichannel analyzer; and (3) automated methods.

Manual Method—Adjust the particle counter to operate in the cumulative mode or total count mode. Refer to the calibration curve obtained earlier, and determine the threshold voltage for the 10- μ m spheres. Adjust 3 channels of the counter to be used in the calibration procedure as follows:

Channel 1 is set for 90% of the threshold voltage.

Channel 2 is set for the threshold voltage.

Channel 3 is set for 110% of the threshold voltage.

Draw a sample through the sensor, observing the count in *Channel 2*. When the particle count in that channel has reached approximately 1000, stop counting, and observe the counts in *Channels 1* and *3*. Check to see if the *Channel 1* count and *Channel 3* count are $1.68 \pm 10\%$ and $0.32 \pm 10\%$, respectively, of the count in *Channel 2*. If not, adjust *Channel 1* and *Channel 3* thresholds to meet these criteria. When these criteria have been satisfied, draw a sample of suspension through the counter until the counts in *Channel 2* have reached approximately 10,000, or until an appropriate volume (e.g., 10 mL) of the sphere suspension has been counted. Verify that *Channel 1* and *Channel 3* counts are $1.68 \pm 3\%$ and $0.32 \pm 3\%$, respectively, of the count in *Channel 2*. Record the particle size for the thresholds just determined for *Channels 1, 2, and 3*. Subtract the particle size for *Channel 2* from the size for *Channel 3*. Subtract the particle size for *Channel 1* from the size for *Channel 2*. The values so determined are the observed standard deviations on the positive and negative side of the mean count for the 10- μ m standard. One commonly used method for calculating the percentage of resolution of the sensor is the following:

$$\% \text{ resolution} = (100/D) \times [(S_{\text{Obs}})^2 - (S_{\text{Std}})^2]^{1/2}$$

in which S_{Obs} is the highest observed standard deviation determined for the sphere standard; S_{Std} is the supplier's reported standard deviation for the spheres; and D is the diameter, in μ m, of the spheres as specified by the supplier. The resolution is not more than 10%.

Automated Method—Software that allows for the automated determination of sensor resolution is available for some counters. This software may be included in the instrument or used in conjunction with a microcomputer interfaced to the counter. The use of these automated methods is appropriate if the vendor supplies written certification that the software provides a resolution determination equivalent to the manual method and if the automated resolution determination is validated as necessary by the user.

Electronic Method—Record the voltage output distribution of the particle sensor, using a multichannel analyzer while sampling a suspension of the 10- μ m particle size standard. To determine resolution, move the cursor of the multichannel analyzer up and down the electric potential scale from the median pulse voltage to identify a channel on each side of the 10- μ m peak that has approximately 61% of the counts observed in the center channel. Use of the counter size response curve to convert the mV values of these two channels to particle sizes provides the particle size at within one standard deviation of the 10- μ m standard. Use these values to calculate the resolution as described under *Manual Method*.

PARTICLE COUNTING ACCURACY—SYSTEM SUITABILITY

Determine the particle counting accuracy of the instrument, using *Method 1* (for sensors requiring the moving window half-count (MWHC) method for calibration), *Method 2* (for multichannel sensors), or *Method 3* for any instrument (manual comparison to membrane microscope method).

Method 1—MWHC Instruments

Procedure—Prepare the suspension and blank using the USP Particle Count RS. With the instrument set to count in the cumulative (total) mode, collect counts at settings of greater than or equal to 10 μ m and greater than or equal to 15 μ m. Prepare the blank and suspension sample in the same manner. Degas the mixture by one of three means: by sonication (at 80 to 120 watts) for about 30 seconds, by allowing to stand, or by vacuum. Gently stir the contents by hand-swirling or by mechanical means, taking care not to introduce air bubbles or contamination. Stir continuously throughout the analysis. Withdraw directly from the container three consecutive volumes. Historically, these have been volumes of not less than 5 mL each, due to instrument limitations and the desire to maximize sample volume. However, where desired, volumes may be utilized that meet the standardization criteria and address the sensitivities of the formulation. Obtain the particle counts, and discard the data from the first portion. [NOTE—Complete the procedure within five minutes.] Repeat the procedure, using the suspension in place of the blank. From the averages of the counts resulting from the analysis of the two portions of the suspension at greater than or equal to 10 μ m and from the analysis of the two portions of the blank at greater than or equal to 10 μ m, calculate the number of particles in each mL by the formula:

$$(P_s - P_b)/V$$

in which P_s is the average particle count obtained from the suspension; P_b is the average particle count obtained from the blank; and V is the average volume, in mL, of the 4 portions tested. Repeat the calculations, using the results obtained at the setting of not less than 15 μ m.

Interpretation—The MWHC instrument meets the requirements for *Particle Counting Accuracy* if the count obtained at ≥ 10 μ m and the ratio of the counts obtained at greater than or equal to 10 μ m to those obtained at greater than or equal to 15 μ m conform to the values that accompany the USP Particle Count RS. If the instrument does not meet the requirements for *Particle Counting Accuracy*, and adequate test volumes remain, repeat the procedure with them; if in-

sufficient volumes remain, prepare new suspension and blank, and then repeat the procedure. If the results of the second test are within the limits given above, the instrument meets the requirements of the test for *Particle Counting Accuracy*. If on the second attempt the system does not meet the requirements of the test, determine and correct the source of the failures, and retest the instrument.

Method 2—Multichannel Instruments

Procedure—Use one of three standards: (1) a dilution of the USP Particle Count Reference Standard (USP PCRS); (2) commercial preparation of standard calibrator spheres of nominal diameter 15 to 30 μm in a suspension containing between 50 and 200 particles per mL, certified by the manufacturer; or (3) a laboratory-prepared suspension of standard calibrator spheres having a nominal diameter of 15 to 30 μm , containing between 50 and 200 particles per mL. Use of non-USP standards 2 and 3 is acceptable when they are compliant with USP standardization criteria: five successive counts are not more than $\pm 10\%$ of stated size.

Degas the suspension by one of three means: by sonication (at 80 to 120 watts) for about 30 seconds, by allowing to stand, or by vacuum. Gently stir the contents by hand-swirling or by mechanical means, taking care not to introduce air bubbles or contamination. Stir continuously throughout the analysis, and perform five counts on 5-mL volumes of the suspension, using the particle counter 10- μm size threshold. Obtain the mean cumulative particle count per mL.

Interpretation—The instrument meets the requirements for *Particle Counting Accuracy* if the count obtained at greater than or equal to 10 μm conforms to the values that accompany the USP Particle Count RS. If the instrument does not meet the requirements for *Particle Counting Accuracy*, repeat the procedure. If the results of the second test are within the limits given above, the instrument meets the requirements of the test for *Particle Counting Accuracy*. If on the second attempt the system does not meet the requirements of the test, determine and correct the source of the failures, and retest the instrument.

Method 3—Alternate Manual Method

Procedure—Prepare a suspension of standard calibrator spheres having a nominal diameter of 15 to 30 μm , containing between 50 and 200 particles per mL. Degas the suspension by one of three means: by sonication (at 80 to 120 watts) for about 30 seconds, by allowing to stand, or by vacuum. Gently stir the contents by hand-swirling or by mechanical means, taking care not to introduce air bubbles or contamination. Stir continuously throughout the analysis and perform five counts on 5-mL volumes of the suspension, using the particle counter 10- μm size threshold. Obtain the mean cumulative particle count per mL. Pipette a volume of this suspension containing 250 to 500 particles into a filter funnel prepared as described for *Microscope Particle Count Test, Filtration Apparatus*, below. After drying the membrane, count the total number of standard spheres collected on the membrane filter. This count should be within 20% of the mean instrumental count per mL for the suspension.

Test Environment

Specimens must be cleaned to the extent that the level of particles added by testing has a negligible effect on the outcome of the test.

Cleanse glassware, closures, and other required equipment, preferably by immersing and cleaning the items using warm, nonionic detergent solution. Rinse in flowing tap water, and then rinse again in flowing filtered water. Organic solvents may also be used to facilitate cleaning. [NOTE—These steps describe one way to clean equipment; alternatively, particulate-free equipment may be obtained from a suitable vendor.] Preferably, the test specimen, glass-

ware, closures, and other required equipment are then finally rinsed with filtered water, using a hand-held pressure nozzle with final filter or other appropriate filtered water source within an environment protected by high-efficiency particulate air (HEPA) filters. While conducting the assay, non-shedding garments and powder-free gloves are worn within the HEPA environment. Perform the test in an environment that does not contribute any significant amount of particulate matter.

To collect blank counts, use a cleaned vessel of the type and volume representative of that to be used in the test. Place a 50-mL or more volume of filtered water in the vessel, and agitate the water sample in the cleaned glassware by inversion or swirling. [NOTE—A smaller volume, consistent with the article to be counted, can be used.] Degas by the same method to be used for the product samples, by one of three means; sonication (at 80 to 120 watts) for about 30 seconds, by vacuum, or by allowing to stand. Swirl the vessel containing the water sample by hand or agitate by mechanical means to suspend particles.

As described in (788): *Determine the particulate matter in 5 samples of filtered water, each of 5 ml. If the number of particles of 10 μm or greater size exceeds 25 for the combined 25 ml (NMT 1/mL), the precautions taken for the tests are not sufficient.*

It is recommended that when utilizing the test for the (789) method, the blank test should be considered failed, if in addition, the number of particles of 25 μm or greater in size exceeds 3.

Test Procedure

TEST PREPARATION

Prepare the test specimens in the following sequence. Outside of the unidirectional airflow cabinet to be used for the test, remove outer closures, sealing bands, but not the sealing closure. If shedding is noted to be an issue, remove or tape over the product labels as well. Place the samples in the test cabinet, and rinse the exteriors of the containers with filtered water as directed under *Test Environment*. Protect the containers from environmental contamination until analyzed. After proper mixing, open and withdraw, pour or otherwise sample the contents of the containers under test in a manner least likely to generate particles that could enter the test specimen. Contents of containers with removable stoppers may be poured out directly after removing the closures. Sampling devices having a needle to penetrate the unit closure may also be employed. Products packaged in flexible plastic containers may be sampled by cutting the medication or administration port tube or a corner from the unit with a suitably cleaned razor blade or scissors. Dry or lyophilized products may be constituted using their internal diluent, by removing the closure to add supplied product diluent or by injecting filtered water via hypodermic syringe. If test specimens are to be pooled, remove the closure and empty the contents into a clean container.

NUMBER OF TEST SPECIMENS

USP (788) provides the sampling plan according to product volume. For all products, regardless of volume, comprehensive experience regarding the integrity and consistency of the batch is gained throughout development, allowing the proper sampling plans to be applied in commercial production that ensure sample selection is representative of batch quality. All batches must have sampling plans that accommodate desired statistical measures of batch quality and facilitate process control.

PRODUCT DETERMINATION

Depending upon the dosage form being tested, proceed as directed under the appropriate category below.

Liquid Preparations—

Volume in Container Less Than 25 mL—Prepare the containers as directed under *Test Preparation*. Mix and suspend the particulate matter in each unit by inverting the unit 20 times. [NOTE—Because of the small volume of some products, it may be necessary to agitate the solution more vigorously to suspend the particles properly.] Open and combine the contents of 10 or more units in a cleaned container to obtain a volume of not less than 25 mL. Degas the pooled solution by one of three means: sonication for about 30 seconds, or by vacuum, or by allowing the solution to stand.

Gently stir the contents of the container by hand-swirling or by mechanical means, taking care not to introduce air bubbles or contamination. Remove four portions, that conform to the volumes utilized in the IST, and count the number of particles equal to or greater than 10 μm and 25 μm . Disregard the result obtained for the first portion. [NOTE—For low-volume products, a pool of 15 or more units may be necessary to achieve a pool volume sufficient for four 5-mL sample aliquots. Smaller sample aliquots (i.e., less than 5 mL) can be used if the assay result obtained with the smaller aliquots is validated to give an assessment of batch suitability equivalent to that obtained with the 5-mL aliquots specified above.]

Volume in Container 25 mL or More—Prepare the containers as directed under *Test Preparation*. Mix and suspend the particulate matter in each unit by inverting the unit 20 times prior to opening the container for degassing. Degas the solution by one of three means: by sonication for about 30 seconds, or by vacuum, or by allowing the solution to stand. When sampling, ensure that the counter probe can be inserted into the middle of the solution. Gently stir the contents of the unit by hand-swirling or by mechanical means. Remove four portions, each of not less than 5 mL, and count the number of particles equal to or greater than 10 μm and 25 μm . Disregard the result obtained for the first portion.

Dry or Lyophilized Preparations—Prepare the containers as directed under *Test Preparation*. Open each container, taking care not to contaminate the opening or cover. Constitute as directed by the labeling, according to the *Test Preparation*. Alternately, depending on the experiment, use:

- filtered water or
- an appropriate laboratory-filtered diluent if suitable.

Replace the closure, and manually agitate the container sufficiently to ensure dissolution of the drug. [NOTE—For some dry or lyophilized products, it may be necessary to let the containers stand for a suitable interval, and then agitate again to effect complete dissolution.] After the drug in the constituted sample is completely dissolved, degas the solution by sonication for about 30 seconds, or by exposing to vacuum, or by allowing the solution to stand. When sampling, ensure that the counter draw or sipping probe can be inserted into the middle of the solution. Gently stir the contents of the unit by hand-swirling or by mechanical means to mix and suspend any particulate matter. Proceed as directed for the appropriate unit volume under *Liquid Preparations*, and analyze by withdrawing a minimum of four portions, each of not less than 5 mL, and count the number of particles equal to or greater than 10 μm and 25 μm . Disregard the result obtained for the first portion.

Products Packaged with Dual Compartments Constructed to Hold the Drug Product and a Solvent in Separate Compartments—Prepare the units to be tested as directed under *Test Preparation* and according to product insert directions. Mix each unit as directed in the labeling, activating and agitating so as to ensure thorough mixing of

the separate components and drug dissolution. Open and degas the units or pooled specimen to be tested by one of three means: sonication, or by vacuum, or by allowing the solution to stand. Proceed as directed for the appropriate unit volume under *Liquid Preparations*, mix and suspend the particulate matter present in each unit by inversion or swirling or by mechanical means and analyze by withdrawing a minimum of four portions, each of not less than 5 mL, and count the number of particles equal to or greater than 10 μm and 25 μm . Disregard the result obtained for the first portion.

Products Labeled “Pharmacy Bulk Package Not for Direct Infusion”—Proceed as directed for *Liquid Preparations* where the volume is 25 mL or more. Calculate the test result on a portion that is equivalent to the maximum dose given in the labeling. For example, if the total bulk package volume is 100 mL and the maximum dose volume is 10 mL, then the average LO particle count per mL would be multiplied by 10 to obtain the test result based on the 10-mL maximum dose. [NOTE—For the calculations of test results, consider this maximum dose portion to be the equivalent of the contents of one full container.]

LO Calculations

Note that the particle limits must be reported as all particles $\geq 10 \mu\text{m}$ and all particles $\geq 25 \mu\text{m}$. If the instrument has been configured to count in differential bins, such as $\geq 10\text{--}25 \mu\text{m}$, $\geq 25\text{--}50 \mu\text{m}$, $\geq 50 \mu\text{m}$, etc., all bins $\geq 10 \mu\text{m}$ must be added to yield total $\geq 10 \mu\text{m}$ count; all bins $\geq 25 \mu\text{m}$ need to be added to yield total count $\geq 25 \mu\text{m}$.

For example, the analyst has counted the test samples in eight bins: a) $\geq 10\text{--}15 \mu\text{m}$, b) $\geq 15 \mu\text{m}\text{--}25 \mu\text{m}$, c) $\geq 25 \mu\text{m}\text{--}40 \mu\text{m}$, d) $\geq 40 \mu\text{m}\text{--}75 \mu\text{m}$, e) $\geq 75 \mu\text{m}\text{--}100 \mu\text{m}$ and f) $\geq 100 \mu\text{m}$. They would then calculate $P_{\geq 10}$ as:

$$P_{\geq 10} = P_{\geq 10\text{--}15 \mu\text{m}} + P_{\geq 15\text{--}25 \mu\text{m}} + P_{\geq 25\text{--}40 \mu\text{m}} + P_{\geq 40\text{--}75 \mu\text{m}} + P_{\geq 75\text{--}100 \mu\text{m}} + P_{\geq 100 \mu\text{m}}$$

Pooled Samples—Average the counts from the two or more aliquot portions analyzed. Calculate the number of particles in each container by the formulae:

$$P_{\Sigma 10} V_T / V_A n$$

$$P_{\Sigma 25} V_T / V_A n$$

in which $P_{\Sigma 10}$ is the average particle count per threshold obtained from all portions analyzed and $P_{\Sigma 25}$ is the average particle count per threshold obtained from all portions $\geq 25 \mu\text{m}$ analyzed. V_T is the volume of pooled sample, in mL; V_A is the volume, in mL, of each portion analyzed; and n is the number of containers pooled.

Individual Samples—Average the counts obtained for the 5-mL or greater aliquot portions from each separate unit analyzed, and calculate the number of particles in each container by the formulae:

$$P_{\Sigma 10} V / V_A$$

$$P_{\Sigma 25} V / V_A$$

in which $P_{\Sigma 10}$ is the average particle count per threshold obtained from all portions analyzed; and $P_{\Sigma 25}$ is the average particle count per threshold obtained from all portions $\geq 25 \mu\text{m}$ analyzed. V is the volume, in mL, of the tested unit; and V_A is the volume, in mL, of each portion analyzed.

Individual Unit Samples—Average the counts obtained for the two or more 5-mL aliquot portions taken from the solu-

tion unit. Calculate the number of particles in each mL of product solution taken by the formulae:

$$P_{\Sigma 10}/V$$

$$P_{\Sigma 25}/V$$

in which $P_{\Sigma 10}$ is the average particle count per threshold obtained from all portions analyzed and $P_{\Sigma 25}$ is the average particle count per threshold obtained from all portions $\geq 25 \mu\text{m}$ analyzed. V is the volume, in mL, of the portion taken.

For all types of product, if the tested material has been diluted to decrease the viscosity, the dilution factor must be accounted for in the calculation of the final test result. For all test results, the particle count $\geq 10 \mu\text{m}$ represents all threshold bin counts.

MEMBRANE MICROSCOPE PARTICLE COUNT TEST

The microscope particulate matter test may be applied to both large-volume and small-volume parenteral injections and to ophthalmic solution products as well. This test enumerates essentially solid³ particulate matter $\geq 10 \mu\text{m}$ in these products, after collection, rinsing and drying on a microporous membrane filter. Since a wide range of test aliquots may be utilized, particle counts may be determined on a per-volume or per-container basis without dilution or extrapolation.

In the performance of the membrane microscope assay, one estimates the size of retained solids viewed at 100 \times magnification, tabulating them into specific size categories. In this process, one may encounter materials on the membrane surface that do not appear solid or substantial, showing little or no surface relief such as a "stain" or discontinuity on the membrane. Chapter 〈788〉 advises not to attempt to size or enumerate such semi-solid particles, due to historical comment from LVP terminal sterilization manufacturers that encountered stain-like brown residues after heat sterilization of Dextrose solutions. However, if not sampling a carbohydrate solution or similarly-performing formulation, recognizing the presence of such material is adds a measure of formulation robustness. Consistent evidence of such materials may be indication that further development research is warranted to understand their content. The nature of these materials and subsequent decision to count or investigate must be based upon product formulation experience. Interpretation of microscopical enumeration may be aided by testing a sample of the solution by the LO particle count or a validated, alternate method.

The Test Apparatus is described in 〈788〉. Additional comments are:

- Use a compound binocular microscope that corrects for changes in interpupillary distance by maintaining a constant tube length.
- The objective must be of 10 \times nominal magnification, a planar achromat or better in quality, with a minimum 0.25 numerical aperture.
- The objective must be compatible with an episcopic illuminator attachment.
- The eyepieces must be matched. In addition, one eyepiece must be designed to accept and focus an eyepiece graticule. The microscope must have a mechanical stage capable of holding and traversing the entire filtration area of a 25-mm or 47-mm membrane filter.
- Two illuminators are required. Both illuminators must be of sufficient output to provide a bright and even source of illumination and may be equipped with blue daylight filters to decrease operator fatigue during use.

- The USP graticule as described in 〈788〉 is used.

Stage Micrometer—Graduated in 10- μm increments, utilized each day-of-use. For initial calibration, utilize a stage micrometer that is certified by NIST to verify the USP graticule installation. Thereafter, for daily calibration/verification, one may utilize a commercial stage micrometer graduated in 10- μm increments to verify proper setup.

Filtration Apparatus—Use a filter funnel suitable for the volume to be tested, generally having an inner diameter of about 16 mm for 25-mm membranes or about 37 mm for 47-mm membranes. The funnel is made of plastic, glass, or stainless steel. Use a filter support made of stainless steel screen or sintered glass as the filtration diffuser. A solvent dispenser capable of delivering solvents filtered through a membrane filter at a range of pressures from 10 psi to 80 psi.

Membranes—As described by 〈788〉; however, finer pore size selections will have smoother surfaces, facilitating the microscopical examination; however, may impede more viscous sample fluid during the assay.

Test Environment

Following discussion is recommended operational detail to enhance the conductance of the MM assay.

It is ideal to use two unidirectional airflow hood (UAFH) or other unidirectional airflow enclosures, one for "wet" sample preparations, and the other an enclosure for the microscope counting phase. The UAFH having a capacity sufficient to envelop the area in which the analysis is prepared. The UAFH provides HEPA-filtered air which typically contains not more than 100 particles (0.5 μm or larger) per cubic foot. A blank determination is necessary at the beginning of each test sequence to verify minimal contribution from the background, equipment and personnel operations. What is the definition of a test sequence? Should it be one per shift, one per product family, one per series of filtrations (manifold) or one per sample? Any of these definitions may be suitable, dependant upon the operational needs of the lab system. The ability to clean glassware between samples, the number of different products being run, and the volume of samples through the lab will determine the appropriate control. However, consider the blank to be a system suitability check, and if it fails, all samples run prior to it up to the previous blank, are suspect.

To determine the blank count, duplicate the sample preparation process, in regard to the apparatus and membrane types. Assemble a clean filtration apparatus with a fresh membrane, rinse the interior with filtered water to drain, then deliver a 50-mL or more volume of filtered water to the filtration funnel while applying vacuum, and draw the entire volume of water through the membrane filter. Remove the membrane from the filter funnel base, and place onto a holding device as will be used for test specimens; typically atop a strip of double-sided tape on a microscope slide or in a commercial membrane holder or Petri dish. After allowing the membrane to dry (it must be counted dry), examine the entire filtration area microscopically at a magnification of 100 \times . If not more than 20 particles $\geq 10 \mu\text{m}$ and not more than 5 particles $\geq 25 \mu\text{m}$ or larger are present within the filtration area, the background particle level is sufficiently low for performance of the microscope assay for 〈788〉. If particle load exceeds these limits, repeat the procedure.

There is value in further limiting the background for both 〈788〉 and 〈789〉 testing in regard to good laboratory practice, and more specifically in regard to the 〈789〉 $\geq 25 \mu\text{m}$ and $\geq 50 \mu\text{m}$ limits, which may be considered more restrictive than injectable limits in consideration of total particle content allowed for the (usually) small unit volumes. Compare total particle load for a small SVI, small LVI versus a 5-mL ophthalmic product in Table 1.

³ Soft particles and semi-solid substances may also be retained.

Table 1. Comparison of Total At-Limit Load for Selected Products.

Size Limit	Blank Count	SVI, 5 mL	LVI, 125 mL	Ophthalmic Product, 5 mL
≥10 μm	20	3000 particles	1500 particles	250 particles
≥25 μm	5	300 particles	250 particles	25 particles
≥50 μm	not defined	N/A	N/A	10 particles

Therefore, in smaller volume (789) applications and in low-particle count injectable product, the laboratory should strive for consistent and lower blank counts such as NMT $5 \geq 10 \mu\text{m}$, NMT $1 \geq 25 \mu\text{m}$ and none $\geq 50 \mu\text{m}$ per blank.

Throughout the operational procedure (in the HEPA environment), it is preferable to use powder-free gloves, and low-shedding clothing. Prior to conducting the test, clean the work surfaces of the unidirectional flow enclosure with an appropriate filtered solvent. Glassware and equipment should be rinsed successively with a warm, residue-free solution of detergent, hot water, filtered distilled or deionized water, and isopropyl alcohol. [NOTE—Prior to use, pass the distilled or deionized water and the isopropyl alcohol through membrane filters having a nominal pore size of $0.2 \mu\text{m}$ or finer.] Perform the rinsing in the unidirectional airflow enclosure. Allow the glassware and filtration apparatus to dry in the unidirectional airflow enclosure, upstream of all other operations. Preferably, the enclosure is located in a separate room that is supplied with filtered air-conditioned air and maintained under positive pressure with respect to the surrounding areas.

MICROSCOPE PREPARATION

The microscope optical alignment and illumination are critical for success of this method. Although it is not difficult to differentiate a $10 \mu\text{m}$ from a $25 \mu\text{m}$ particle at $100\times$ with reflected light, the decision regarding the boundary at each size category will be difficult with poor equipment, maintenance or optical alignment. Also operator fatigue is caused by poor microscope alignment. We will have to make decisions such as “is this particle $9 \mu\text{m}$ or $11 \mu\text{m}$?” and “is that particle $24 \mu\text{m}$ or $26 \mu\text{m}$?” Optimized system resolution, that is, the ability to discern discrete points of minimal separation, relies upon good optical systems, aligned well. Factors including instrument cleanliness, resolution, e.g., objective N.A.,⁴ focus of both eyepieces and the graticule will play significant roles in attaining best images. In consideration of optimizing the use of the binocular compound microscope, it is best to utilize operators familiar with the instrument, and comfortable with alignment. The operator conducting the method should align the optics and illumination for their use, with supervisory/trainer approval.

It is recommended to start with alignment of the microscope for a typical transmitted illumination observation using a known sample. Any specimen familiar to the operator will suffice; however, a common particle count reference standard suspension such as the USP PCRS is a recommended selection, since it is also utilized in method system suitability evaluation. A drop of the USP PCRS is placed between a glass microscope slide and cover slip and viewed microscopically.⁵ With appropriate interpupillary distance and a comfortable sitting position at the microscope, the operator examines the fields of suspended spheres. One should observe the small standard spheres crisply in a combined field (with ease) for both eyes. One attains crisp focus

⁴N.A. is numerical aperture, an indicator of optical light-gathering capability, and thus resolution. High N.A. correlates to high resolution.

⁵The microscope objective requires a defined cover slip thickness, nominally $170 \mu\text{m}$, or No. 1 $\frac{1}{2}$.

and ease of view after separate focal adjustment of each eyepiece focus for a single point on the specimen.

Rotate the graticule in the right microscope eyepiece so that the linear scale is located at the bottom of the field of view, bringing the graticule into sharp focus by adjusting the right eyepiece diopter ring while viewing an out-of-focus specimen. Focus the microscope on a specimen, looking through the right eyepiece only. Then, looking through the left eyepiece, adjust the left eyepiece diopter to bring the specimen into sharp focus.

When the operator is not comfortable using the microscope or does not attain an equivalent crisp focus for each eye in a merged field of view, the counting will become a difficult experience and fatigue and flawed size comparison will result.

Nothing is better for preparing the operator for counting particles than to examine a test membrane as a positive control. Seasoned microscopists may not require this step, but for new operators or individuals conducting many different types of methods in the modern laboratory, familiarization is a prudent exercise. A filter membrane of the type being used for the method, such as a 25-mm color-contrast, plain $0.45\text{-}\mu\text{m}$ nominal pore size, containing particles, is a good choice. This may be a sample from previous method that contains a variety of particle types, or one prepared for familiarization. This positive test control will contain natural particles (flakes, threads, equant particles, various colors/opacity, a range of sizes, etc.) to effectively refresh the operator's sensitivity and facilitate microscope and illumination alignment for optimal viewing.

One would examine the membrane preparation, locate a typical array of particles and first bring the illumination into good alignment:

1. Adjust the external, incident illumination at an oblique angle ($10\text{--}20^\circ$ to the method) so that an even ellipse of reflected light is visible on the membrane and an even illumination evident through the eyepiece field of view (even across the full field). Shadows will be evident from larger particles, such as those with z axis $> 5 \mu\text{m}$ (z axis is the microscope optical axis).
2. Adjust the internal episcopic brightfield illuminator to yield an even illumination at a high setting on the transformer control, but more importantly, when dialing down the illumination one observes the evident shadow from the larger particles. In this manner, the high reflectivity of flat, glassy particles (find one) and the distinct shadows of more equant ($x:y:z \sim 1:1:1$) particles is evident.

USING THE CIRCULAR DIAMETER GRATICULE

The USP graticule is specifically fabricated for each microscope. The relative error of the graticule used must be $\pm 2\%$ and is initially measured with an NIST-certified stage micrometer. To accomplish this, align the graticule micrometer scale with the stage micrometer so that they are parallel. (Compare the scales, using as large a number of graduations on each as possible.) Read the number of graticule scale divisions, GSD, compared to stage micrometer divisions, SMD. Calculate the relative error by the formula:

$$100[(\text{GSD} - \text{SMD})/\text{SMD}]$$

A relative error of $\pm 2\%$ is acceptable and verifies good alignment, focus and proper magnification. Thereafter, a day-of-use verification by the microscope operator with the NIST stage micrometer or commercial stage micrometer is sufficient to demonstrate proper setup.

The basic technique of measurement applied with the use of the circular diameter graticule is to count all particles $10 \mu\text{m}$ and larger, further categorizing in $\geq 10 \mu\text{m}$ and $\geq 25 \mu\text{m}$. The circular zone or graticule field of view is a useful zone for active sizing and counting. Particles are compared to the

linear scale and/or circles to determine their size in equivalent circular diameter. This is conducted by transforming mentally the image of each particle into a circle and then comparing to the 10- and 25- μm graticule reference circles. The sizing process is carried out without superimposing the particle on the reference circles; particles are not moved from their locations within the graticule field of view (the large circle) for comparison to the reference circles. Compare the area of the particle being sized to that of the black or transparent circles. Use the area of the clear graticule reference circles to size white or transparent particles. Use the area of the black reference circles to size dark particles. The intent of comparing particles to an equivalent circular diameter is correlation to the LO particle sizing methodology, for which many manufacturers have extensive databases. In practice, particles with nearly circular areas will correlate well with the graticule circle diameters. For particles with one long axis, such as rods and needles, the conversion to circular area will produce more significant bias to smaller estimated sizes. It may be simpler, and most conservative, to count particles in longest chord. To use an extreme example, the total count of mono-dispersions of fine needle crystals would vary greatly dependant upon the size determination utilized.

In order to properly focus the ocular lenses and attain balanced single-field view, each operator must bring the USP graticule lines into sharp focus by adjusting the eyepiece diopter ring (it helps to have an "infinite" view, or out-of-focus specimen). Next, focus the microscope on a specimen, through this same eyepiece, and then looking only through the other eyepiece, adjust its diopter ring to bring the specimen into sharp focus. The USP graticule and specimen particles are now in focus on a well-balanced illumination field.

Preparation of Filtration Apparatus and Test Preparations are covered by (788). Further, prepare the test specimens in the following sequence. Outside of the unidirectional airflow cabinet to be used for the test, remove outer closures, sealing bands, and remove or tape over labels. Rinse the exteriors of the containers with filtered water as directed under Test Environment. Protect the containers from environmental contamination until analyzed.

Within the HEPA cabinet, open and withdraw, pour, or otherwise sample the contents of the containers under test in a manner least likely to generate particles that could enter the test specimen. Contents of containers with removable stoppers may be withdrawn directly by removing the closures. Sampling devices having a needle to penetrate the unit closure may also be employed. Products packaged in flexible plastic containers may be sampled by cutting the medication or administration port tube or a corner from the unit with a suitably cleaned razor blade or scissors.

For all products, regardless of volume, comprehensive experience regarding the integrity and consistency of the batch is gained throughout development, allowing the proper sampling plans to be applied in commercial production that ensure sample selection is representative of batch quality. All batches must have sampling plans that accommodate desired statistical measures of batch quality and facilitate process control.

PRODUCT PARTICLE COUNT DETERMINATION

Depending upon the dosage form being tested, proceed as directed under the appropriate category below.

Liquid Preparations—Thoroughly mix the units to be tested by inverting 20 times. Open the units in a manner consistent with the generation of the lowest possible numbers of background particles. For products less than 25 mL in volume, one may open them and drain to the filtration barrel individually, or combine the contents of 10 or more units in a cleaned container. [NOTE—When pooling containers, these must be included in the blank determination step.] Filter large-volume injection units individually. Small-

volume injection units having a volume of 25 mL or more may be filtered individually.

Transfer to the filtration funnel the total volume of a solution pool or of a single unit, and apply vacuum. If the volume of solution to be filtered exceeds the volume of the filtration funnel, add, stepwise, a portion of the solution until the entire volume is filtered. It is prudent to maintain the liquid volume in the filtration funnel above one-half of the funnel volume between refills, especially if the partial count procedure is to be used (see *Enumeration of Particles, Partial Count Procedure*, below). [NOTE—This is necessary in order to ensure even distribution of particles on the analytical membrane.] After the last addition of solution, begin rinsing the walls of the funnel by directing a low-pressure stream of filtered water in a circular pattern along the walls of the funnel, and stop rinsing the funnel before the volume falls below about one-fourth of the fill level. Maintain the vacuum until all the liquid in the funnel is gone.

Remove the filtration funnel from the filtration base while maintaining vacuum, then turn the vacuum off, and remove the filter membrane with non-serrated forceps. Place the filter in the prepared holder and label with sample identification. Allow the filter to air-dry in the unidirectional airflow enclosure with the cover ajar.

Dry or Lyophilized Preparations—Prepare the containers as directed under *Test Preparation*. Open each container, taking care not to contaminate the opening or cover. Constitute as directed by the labeling, according to the *Test Preparation*. Alternately, depending on the experiment, use:

- filtered water or an appropriate laboratory-filtered diluent if suitable.

Products Packaged with Dual Compartments Constructed to Hold the Drug Product and a Solvent in Separate Compartments—Activate each unit as directed in the labeling, agitating the contents sufficiently to ensure thorough mixing of the separate components, and then proceed as directed for *Liquid Preparations*.

Pharmacy Bulk Packages or Multiple-Dose Containers—For *Products Labeled "Pharmacy Bulk Package—Not for Direct Infusion"* or for multiple-dose containers, proceed as directed for *Liquid Preparations*, filtering the total unit volume.

Calculate the test result on a portion that is equal to the maximum dose given in the labeling. Consider this portion to be the equivalent of the contents of one full container. For example, if the total bulk package volume is 100 mL and the maximum dose listed is 10 mL, the microscope total unit volume count test result would be multiplied by 0.1 to obtain the test result for the 10-mL dose volume. [NOTE—For calculation of the test result, consider this portion to be the equivalent of the contents of one full container.]

Enumeration of Particles

The microscope test described in this section is flexible in that typical artifacts such as air and immiscible liquids do not interfere with the final count. The method has a broad size detection and counting range, if applying the partial count procedure. This method may be used where all particles on an analysis membrane surface are counted or where only those particles on some fractional area of a membrane surface are counted.

TOTAL COUNT PROCEDURE

The microscope method can be tedious (boring), imprecise (poor agreement within and between labs) and particle sizing can be inaccurate for non-spherical or equant particle shapes. Operator fatigue is promoted by poor ergonomic fit (chair height), by poor or imbalanced ocular focus and by excessive eye movement. Restricting the eye movement to a field-defining graticule such as the USP counting graticule restricts eye movement to the central one-third field of

view. This significantly limits eye movement and thus fatigue.

Sample size is an important consideration in counting precision. Care must be taken to sample many containers within a batch for good representation of the particle distribution. Accordingly, the portion of the individual package sampled is key. Particles may float or settle. Sampling only the first 25 mL of a LVP or sampling without adequate and recent mixing is a mistake, and will lead to serious undercounting. Sampling whole, well-mixed containers with the particles in suspension is the best approach.

Counting the isolated particles is an important parameter. Counting all of the particles retained on the membrane is certainly the best approach, and then the simple problem is determining the correct size for placement into the threshold bins, 10 μm and 25 μm . This will be increasingly important for methods utilizing additional bins for population determination, such as 5 μm , 50 μm , 100 μm , etc. Note that the particle limits for (788) and (789) must be reported as all particles $\geq 10 \mu\text{m}$ and all particles $\geq 25 \mu\text{m}$. If the lab method has been configured to count in several bins, such as $\geq 10\text{--}25 \mu\text{m}$, $\geq 25\text{--}50 \mu\text{m}$, $\geq 50 \mu\text{m}$, etc., all bins $\geq 10 \mu\text{m}$ must be added to yield total $\geq 10 \mu\text{m}$ count; all bins $\geq 25 \mu\text{m}$ need to be added to yield total count $\geq 25 \mu\text{m}$. Using a number of narrow size bins may be beneficial in product improvement efforts to separate particle groups.

In performance of a total count, the graticule field of view (GFOV) is defined by the large circle of the graticule, and the vertical crosshair is used as a counting target. Scan the membrane in paths that cover the effective filtration area (EFA), adjoining but not overlapping previous scan paths. Repeat this procedure, tabulating particle counts minimally in the $\geq 10 \mu\text{m}$ –25 μm and $\geq 25 \mu\text{m}$ thresholds, moving across the membrane until all particles on the membrane within the EFA are counted. Record the total number of particles that are $\geq 10 \mu\text{m}$ –25 μm and the number that are $\geq 25 \mu\text{m}$ or larger.

For large-volume products, calculate the particle count, in particles per mL, for each unit tested by the formulas:

$$P_{\geq 10}/V$$

$$P_{\geq 25}/V$$

in which $P_{\geq 10}$ is the total particle count obtained from all portions analyzed, $P_{\geq 25}$ is the total particle count obtained from all portions $\geq 25 \mu\text{m}$ analyzed, and V is the volume, in mL, of the solution tested.

For example, the analyst has counted the test samples in four bins: (a) $\geq 10\text{--}25 \mu\text{m}$, (b) $\geq 25 \mu\text{m}$ –50 μm , (c) $\geq 50 \mu\text{m}$ –100 μm , and (d) $\geq 100 \mu\text{m}$. They would then calculate as:

$$P_{\geq 10} = P_{\geq 10\text{--}25 \mu\text{m}} + P_{\geq 25 \mu\text{m}\text{--}50 \mu\text{m}} + P_{\geq 50 \mu\text{m}\text{--}100 \mu\text{m}} + P_{\geq 100 \mu\text{m}}$$

For small-volume products, calculate the particle count, in particles per container, by the formulas:

$$P_{\geq 10}/n$$

$$P_{\geq 25}/n$$

in which $P_{\geq 10}$ is the total particle count obtained from all portions analyzed, $P_{\geq 25}$ is the total particle count obtained from all portions $\geq 25 \mu\text{m}$ analyzed, and n is the number of units pooled (1 in the case of an individual unit).

PARTIAL COUNT PROCEDURE

When encountering a membrane full of particles, the task of counting all of them, properly, is daunting. Consider that an SVP with an at-limit content of small particles, sampled in a 10-vial pool would have 30,000 10- μm particles on the

membrane. Partial or statistical counting of the membrane effective filtration area may be the only means to attain reasonable results. Partial counting should not be used to reduce count times, just as a means to estimate the total load on a high-count isolate. A field-defining device, such as grids on the membrane surface or an ocular graticule field of view have been used reliably. An ocular graticule provides a sharp boundary for area definition. Gridded membrane lines are rather broad and have ink-spatter that may be taken for particulate matter.

Which portions and how much of the EFA should be counted? In consideration of 25-mm membranes, the EFA is 16-mm diameter using typical commercial filtration funnels, and thus $(\pi \times r^2) = 201 \text{ mm}^2$. Based upon earlier proposals from the HIMA committee and discussion by Draftz (see *Reference 3*), acceptable confidence intervals (Poisson distribution, 2 standard deviations) dictate that for samples with less than 1000 particles, the imprecision of statistical counting is objectionable. Full count is recommended for such samples. For samples with more than 1000 particles on the isolate membrane, using a 25-mm membrane, a reasonable estimate of particle population is attained using 20 GFOV. If a smaller confidence interval about the result is desired, a larger number of fields and particles may be counted.

For 47-mm membranes, the EFA is 37 mm. These larger diameter membranes may be selected for formulations needing more membrane surface area (having slow flow characteristics through 25-mm membranes) the EFA $= (\pi \times r^2) = (\pi \times 18.5 \text{ mm}^2) = 1075 \text{ mm}^2$. Thus, for 47-mm membrane EFAs, many more GFOVs must be counted to attain similar confidence. Using 100 GFOVs for partial counting of 47-mm membranes provides similar statistical confidence to the 20 GFOV/25-mm approach. Accordingly, when a particle load of 1000 or less is present, a full count is recommended.

When a partial count of particles on a membrane is to be performed, the analyst must first ensure that an even distribution of particles is present on the membrane. This is assessed by rapid scanning at 50 \times to qualitatively scan for heterogeneity or clumps of particles. If heterogeneity is observed, one should perform a full count on the membrane. Next, count the 10- μm or larger particles in one GFOV at the edge of the filtration area as well as one in the center of the membrane. The number of $\geq 10\text{--}\mu\text{m}$ or larger particles in the GFOV with the highest total particle count must not be more than twice that of the GFOV with the lowest particle count. Fully count the membrane failing these criteria.

To perform a partial count of the particles on a membrane, include all particles $\geq 10\text{--}25 \mu\text{m}$ and $\geq 25 \mu\text{m}$ within the GFOV and those that are in contact with the right side of the GFOV circle. Do not count particles outside of the GFOV. Ignore those that touch the left side of the GFOV circle. The dividing line between right and left sides of the GFOV circle is the vertical cross hair and is a useful counting line. [NOTE—Make the best possible judgment on particle size without changing the membrane position, microscope magnification or illumination.]

Start at the center edge of the filtration area and begin counting adjacent GFOVs. When the other edge of the filtration area is reached, move one GFOV toward the top of the filter and continue counting GFOVs by moving in the opposite direction. Moving from one GFOV to the next can be accomplished by one of two methods. One method is to define a landmark (particle or surface irregularity in the filter) and move over one GFOV in relation to the landmark. A second method is to use the vernier on the microscope method to move 1 mm between GFOVs. To facilitate the latter, adjust the microscope x- and y-method positioning controls to a whole number at the starting position at the center right edge of the filtration area, then each GFOV will be one whole division of movement of the x-method positioning control. If the top of the filtration area is reached before the desired number of GFOVs is reached, begin again at the right center edge of the filtration area one GFOV

lower than the first time. This time move downward on the membrane when the end of a row of GFOVs is reached. Continue as before until the number of GFOVs is complete.

For large-volume products, extrapolate the total count of particles per mL by the formulas:

$$P_{\Sigma 10} A_T / A_P V$$

$$P_{\Sigma 25} A_T / A_P V$$

in which $P_{\Sigma 10}$ is the total particle count obtained from all fields of view and all size thresholds; $P_{\Sigma 25}$ is the total particle count obtained from all fields of view and all size thresholds $\geq 25 \mu\text{m}$; A_T is the filtration area, in mm^2 , of the membrane (inner filtration barrel diameter); A_P is the partial area counted, in mm^2 , based on the number of graticule fields counted (GFOV area \times number of GFOV counted); and V is the volume, in mL, of solution filtered.

For a solution pool (for small-volume product units containing less than 25 mL) or for a single unit of a small-volume product, extrapolate the total count of particles per unit by the formulas:

$$P_{\Sigma 10} A_T / A_P n$$

$$P_{\Sigma 25} A_T / A_P n$$

in which $P_{\Sigma 10}$ is the total particle count obtained from all fields of view and all size thresholds, $P_{\Sigma 25}$ is the total particle

count obtained from all fields of view and all size thresholds $\geq 25 \mu\text{m}$, and n is the number of units counted (1 in the case of an individual unit). For all types of product, if the tested material has been diluted to decrease viscosity, the dilution factor must be accounted for in the calculation of the final test result.

Dietary Supplements

General Chapters Information

(2021) MICROBIAL ENUMERATION TESTS— NUTRITIONAL AND DIETARY SUPPLEMENTS

INTRODUCTION

This chapter provides tests for the estimation of the number of viable aerobic microorganisms present in nutritional supplements of all kinds, from raw materials to the finished forms. Alternative methods may be substituted for the tests, provided that they have been properly validated as giving equivalent or better results. In preparing for and in applying the tests, observe aseptic precautions in handling the specimens. The term “growth” is used in a special sense herein, i.e., to designate the presence and presumed proliferation of viable microorganisms.

PREPARATORY TESTING

The validity of the results of the tests set forth in this chapter rests largely upon the adequacy of a demonstration that the test specimens to which they are applied do not, of themselves, inhibit the multiplication, under the test conditions, of microorganisms that may be present. Therefore, preparatory to conducting the tests on a regular basis and as circumstances require subsequently, inoculate diluted specimens of the material to be tested with separate viable cultures of the challenge microorganisms.

For the *Soybean–Casein Digest Agar* used for *Total Aerobic Microbial Counts*, inoculate duplicate plates with 25 to 250 cfu of *Staphylococcus aureus* (ATCC¹ No. 6538), *Escherichia coli* (ATCC No. 8739), and *Bacillus subtilis* (ATCC No. 6633) to demonstrate a greater than 70% bioburden recovery in comparison to a control medium. For the *Sabouraud Dextrose Agar* used for *Total Combined Yeast and Mold Counts*, inoculate duplicate plates with 25 to 250 cfu of *Candida albicans* (ATCC No. 10231) and *Aspergillus niger* (ATCC No. 16404) to demonstrate a greater than 70% bioburden recovery in comparison to a control medium. For *Enterobacterial Probable Number Determinations (Bile-Tolerant Gram-Negative Bacteria)*, appropriate dilutions of *Escherichia coli* (ATCC No. 8739) and *Salmonella typhimurium* (ATCC No. 13311) are used. Failure of the organism(s) to grow in the relevant medium invalidates that portion of the examination and ne-

¹Available from ATCC, 10801 University Boulevard, Manassas, VA 20110-2209. Equivalent microorganisms, provided that they are from a national collection repository, can be used in lieu of ATCC strains. However, the viable microorganisms used in the test must not be more than five passages removed from the original ATCC or national collection culture.

cessitates a modification of the procedure by (1) an increase in the volume of diluent, the quantity of test material remaining the same, or by (2) the incorporation of a sufficient quantity of suitable inactivating agent(s) in the diluents, or by (3) an appropriate combination of modifications to (1) and (2) so as to permit growth of the inoculum.

The following are examples of ingredients and their concentrations that may be added to the culture medium to neutralize inhibitory substances present in the sample: soy lecithin, 0.5%; and polysorbate 20, 4.0%. Alternatively, repeat the test as described in the preceding paragraph, using *Fluid Casein Digest–Soy Lecithin–Polysorbate 20 Medium* to demonstrate neutralization of preservatives or other antimicrobial agents in the test material. Where inhibitory substances are contained in the product and the latter is soluble, a suitable, validated adaptation of a procedure set forth under *Procedures* using the *Membrane Filtration Method* may be used.

If, in spite of the incorporation of suitable inactivating agents and a substantial increase in the volume of diluent, it is still not possible to recover the viable cultures described above, and where the article is not suitable for the employment of membrane filtration, it can be assumed that the failure to isolate the inoculated organism is attributable to the bactericidal or bacteriostatic activity of such magnitude that treatments are not able to remove the activity. This information serves to indicate that the article is not likely to allow proliferation or contamination with the given species of microorganism. Monitoring should be continued in order to determine the inhibitory range and bactericidal activity of the article.

BUFFER SOLUTION AND MEDIA

Culture media may be prepared as follows, or dehydrated culture media may be used provided that, when reconstituted as directed by the manufacturer or distributor, they have similar ingredients and/or yield media comparable to those obtained from the formulas given herein.

In preparing media by the formulas set forth herein, dissolve the soluble solids in the water, using heat if necessary to effect complete solution, and add solutions of hydrochloric acid or sodium hydroxide in quantities sufficient to yield the desired pH in the medium when it is ready for use. Determine the pH at $25 \pm 2^\circ$.

Where agar is called for in a formula, use agar that has a moisture content of not more than 15%. Where water is called for in a formula, use *Purified Water*.

pH 7.2 Phosphate Buffer

Prepare a stock solution by dissolving 34 g of monobasic potassium phosphate in about 500 mL of water contained in a 1000-mL volumetric flask. Adjust to a pH of 7.2 ± 0.1 by the addition of sodium hydroxide TS (about 175 mL), add water to volume, and mix. Dispense and sterilize. Store

under refrigeration. For use, dilute the stock solution with water in the ratio of 1 to 800, dispense as desired, and sterilize.

Media

Prepare media for the tests as described below. Alternatively, dehydrated formulations may be used provided that, when reconstituted as directed by the manufacturer or distributor, they meet the requirements of the *Growth Promotion Testing*. Unless otherwise indicated elsewhere in this chapter, media are sterilized in autoclaves using a validated process. The exposure time within the autoclave at 121° will depend on the volume of media to be sterilized. Thus, for example, a 500-mL volume would need to be autoclaved using a temperature and time relationship that will ensure that the medium has attained at least an F_0 of 12–15 in the sterilization process. However, the appropriate time and temperature duration for sterilizing prepared media at any given volume should be confirmed by a thermal penetration study using a thermocouple or thermoprobe placed within the liquid medium.

FLUID CASEIN DIGEST–SOY LECITHIN–POLYSORBATE 20 MEDIUM

Pancreatic Digest of Casein	20 g
Soy Lecithin	5 g
Polysorbate 20	40 mL
Water	960 mL

Dissolve pancreatic digest of casein and soy lecithin in 960 mL of water, heating in a water bath at 48° to 50° for about 30 minutes to effect solution. Add 40 mL of polysorbate 20. Mix, dispense as desired, and sterilize.

SOYBEAN–CASEIN DIGEST–AGAR MEDIUM

Pancreatic Digest of Casein	15.0 g
Papaic Digest of Soybean Meal	5.0 g
Sodium Chloride	5.0 g
Agar	15.0 g
Water	1000 mL

pH after sterilization: 7.3 ± 0.2 .

FLUID SOYBEAN–CASEIN DIGEST MEDIUM

Pancreatic Digest of Casein	17.0 g
Papaic Digest of Soybean Meal	3.0 g
Sodium Chloride	5.0 g
Dibasic Potassium Phosphate	2.5 g
Dextrose	2.5 g
Purified Water	1000 mL

Dissolve the solids in the water, heating slightly to effect a solution. Cool the solution to room temperature, and adjust the pH with 1 N sodium hydroxide so that after sterilization it will have a pH of 7.3 ± 0.2 . Filter, if necessary, and dispense into suitable containers. Sterilize at a temperature and time relationship that will ensure that the medium has attained at least an F_0 of 12–15 in the sterilization process, or by a validated filtration process.

SABOURAUD DEXTROSE–AGAR MEDIUM

Dextrose	40.0 g
Mixture of Peptic Digest of Animal Tissue and Pancreatic Digest of Casein (1:1)	10.0 g
Agar	15.0 g
Water	1000 mL

Mix, and boil to effect solution.
pH after sterilization: 5.6 ± 0.2 .

VIOLET-RED BILE AGAR WITH GLUCOSE AND LACTOSE

Yeast Extract	3.0 g
Pancreatic Digest of Gelatin	7.0 g
Bile Salts	1.5 g
Lactose	10.0 g
Sodium Chloride	5.0 g
D-Glucose Monohydrate	10.0 g
Agar	15.0 g
Neutral Red	30 mg
Crystal Violet	2 mg
Water	1000 mL

Adjust the pH so that it is 7.4 ± 0.2 after heating. Heat to boiling, but do not heat in an autoclave. Pour onto plates.

MOSSEL–ENTEROBACTERIACEAE ENRICHMENT BROTH

Pancreatic Digest of Gelatin	10.0 g
D-Glucose Monohydrate	5.0 g
Dehydrated Ox Bile	20.0 g
Monobasic Potassium Phosphate	2.0 g
Dibasic Potassium Phosphate	8.0 g
Brilliant Green	15 mg
Water	1000 mL

Suspend the solids in water, and heat to boiling for 1 to 2 minutes. Transfer 120-mL portions to 250-mL volumetric flasks or 9-mL portions to test tubes, all being capped with cotton plugs or loose-fitting caps. Heat on a steam bath for 30 minutes. Adjust the pH so that it is 7.2 ± 0.2 after heating.

GROWTH PROMOTION TESTING

Each lot of dehydrated medium bearing the manufacturer's identifying number or each lot of medium prepared from basic ingredients must be tested for its growth-promoting qualities. Cultures of *Staphylococcus aureus* (ATCC No. 6538), *Escherichia coli* (ATCC No. 8739), *Bacillus subtilis* (ATCC No. 6633), *Candida albicans* (ATCC No. 10231), and *Aspergillus niger* (ATCC No. 16404) are used. A 10^{-3} dilution of a 24-hour broth culture of the microorganism to the first dilution (in pH 7.2 Phosphate Buffer or Fluid Soybean–Casein Digest Medium) may be used as the inocula. Serially streak plates of the media with the appropriate inocula to obtain isolated colonies to demonstrate the growth-promotion qualities of the Soybean–Casein Digest and Sabouraud Dextrose Agar media. Inoculate the Fluid Soybean–Casein Digest Medium and Mossel–Enterobacteriaceae Enrichment Broth with

10 to 100 cfu of the appropriate challenge organisms to demonstrate their growth-promotion qualities.

SAMPLING

Provide 10-mL or 10-g specimens for the tests called for in the individual monograph.

PROCEDURE

Prepare the specimen to be tested by a treatment that is appropriate to its physical characteristics and that does not alter the number and kind of microorganisms originally present, in order to obtain a solution or suspension of all or part of it in a form suitable for the test procedure(s) to be carried out.

For a solid that dissolves to an appreciable extent but not completely, reduce the substance to a moderately fine powder, suspend it in the vehicle specified, and proceed as directed under *Total Aerobic Microbial Count*.

For a fluid specimen that consists of a true solution, or a suspension in water or a hydroalcoholic vehicle containing less than 30% of alcohol, and for a solid that dissolves readily and practically completely in 90 mL of pH 7.2 Phosphate Buffer or the media specified, proceed as directed under *Total Aerobic Microbial Count*.

For water-immiscible products, prepare a suspension with the aid of a minimal quantity of a suitable, sterile emulsifying agent (such as one of the polysorbates), using a mechanical blender and warming to a temperature not exceeding 45°, if necessary, and proceed with the suspension as directed under *Total Aerobic Microbial Count*.

Total Aerobic Microbial Count

For specimens that are freely soluble, use the *Membrane Filtration Method* or *Plate Method*. For specimens that are sufficiently soluble or translucent to permit use of the *Plate Method*, use that method; otherwise, use the *Multiple-Tube Method*. With either method, first dissolve or suspend 10.0 g of the specimen if it is a solid, or 10 mL, accurately measured, if the specimen is a liquid, in pH 7.2 Phosphate Buffer, *Fluid Soybean–Casein Digest Medium*, or *Fluid Casein Digest–Soy Lecithin–Polysorbate 20 Medium* to make 100 mL. For viscous specimens that cannot be pipeted at this initial 1:10 dilution, dilute the specimen until a suspension is obtained, i.e., 1:50 or 1:100, etc., that can be pipeted. Perform the test for absence of inhibitory (antimicrobial) properties as described under *Preparatory Testing* before the determination of *Total Aerobic Microbial Count*. Add the specimen to the medium not more than 1 hour after preparing the appropriate dilutions for inoculation.

Membrane Filtration Method

Dilute the fluid further, if necessary, so that 1 mL will be expected to yield between 30 and 300 colonies. Pipet 1 mL

of the final dilution into 5 to 10 mL of pH 7.2 Phosphate Buffer, *Fluid Soybean–Casein Digest Medium*, or *Fluid Casein Digest–Soy Lecithin–Polysorbate 20 Medium*. Wash each membrane with an appropriate amount of one of the above diluents. Transfer each membrane to a Petri dish containing *Soybean–Casein Digest Agar Medium*, previously solidified at room temperature. Incubate the plates at a temperature between 30° and 35° for 48 to 72 hours. Following incubation, examine the plates for growth, count the number of colonies, and express the average for the two plates in terms of the number of microorganisms per g or per mL of specimen. If no microbial colonies are recovered from the dishes representing the initial 1:10 dilution of the specimen, express the results as “less than 10 microorganisms per g or per mL of specimen.”

Plate Method

Dilute the fluid further, if necessary, so that 1 mL will be expected to yield between 30 and 300 colonies. Pipet 1 mL of the final dilution onto each of two sterile Petri dishes. Promptly add to each dish 15 to 20 mL of *Soybean–Casein Digest–Agar Medium*, previously melted and cooled to about 45°. Cover the Petri dishes, mix the sample with agar by gently tilting or rotating the dishes, and allow the contents to solidify at room temperature. Invert the Petri dishes and incubate for 48 to 72 hours. Following incubation, examine the plates for growth, count the number of colonies, and express the average for the two plates in terms of the number of microorganisms per g or per mL of specimen. If no microbial colonies are recovered from the dishes representing the initial 1:10 dilution of the specimen, express the results as “less than 10 microorganisms per g or per mL of specimen.”

Multiple-Tube Method

Into each of 14 test tubes of similar size, place 9.0 mL of sterile *Fluid Soybean–Casein Digest Medium*. Arrange 12 of the tubes in four sets of three tubes each. Put aside one set of three tubes to serve as the controls. Into each of three tubes of one set (“100”) and into a fourth tube (A) pipet 1 mL of the solution or suspension of the specimen, and mix. Pipet 1 mL from tube A into the one remaining tube (B), not included in a set, and mix. These two tubes contain 100 mg or 100 µL and 10 mg or 10 µL of the specimen, respectively. Into each of the second set (“10”) of three tubes pipet 1 mL from tube A, and into each tube of the third set (“1”) pipet 1 mL from tube B. Discard the unused contents of tubes A and B. Close well, and incubate all of the tubes. Following incubation, examine the tubes for growth: the three control tubes remain clear, and the observations in the tubes containing the specimen, when interpreted by reference to *Table 1*, indicate the most probable number of microorganisms per g or per mL.

Table 1. Most Probable Count by Multiple-Tube Method

Observed Combinations of Numbers of Tubes Showing Growth in Each Set			Most Probable Number of Microorganisms per g or per mL	
Number of mg or µL of specimen per tube				
100	10	1		
3	3	3		more than 1100
3	3	2		1100
3	3	1		500
3	3	0		200
3	2	3		290
3	2	2		210
3	2	1		150

Table 1. Most Probable Count by Multiple-Tube Method (Continued)

Observed Combinations of Numbers of Tubes Showing Growth in Each Set			Most Probable Number of Microorganisms per g or per mL
Number of mg or μ L of specimen per tube			
100	10	1	
3	2	0	90
3	1	3	160
3	1	2	120
3	1	1	70
3	1	0	40

3	0	2	60
3	0	1	40
3	0	0	23
2	2	0	21
2	1	1	20
2	1	0	15
2	0	1	14
2	0	0	9
1	2	0	11
1	1	0	7
1	0	0	4
0	1	0	3
0	0	0	<3

Total Combined Molds and Yeasts Count

Procedure—Proceed as directed for *Membrane Filtration Method* or *Plate Method* under *Total Aerobic Microbial Count*, except to use the same amount of *Sabouraud Dextrose–Agar Medium* instead of *Soybean–Casein Digest–Agar Medium* and to incubate the plates for 5 to 7 days at 20° to 25°.

Retest—For the purpose of confirming a doubtful result by any of the procedures outlined in the foregoing tests following their application to a 10-g specimen, a retest on an additional 10-g specimen from the original sample and a 10-g specimen from the new sample of the nutritional supplement may be conducted. Proceed as directed under *Procedure*.

Enterobacterial Count (Bile-Tolerant Gram-Negative Bacteria)

Dissolve or suspend the sample in a sufficient volume of pH 7.2 Phosphate Buffer or Fluid Soybean–Casein–Digest Medium and dilute with Fluid Soybean–Casein–Digest Medium to 100 mL. Pre-incubate for 2 to 5 hours at 20°–25° in Soybean–Casein Digest Broth diluent; inoculate suitable quantities of *Mossel–Enterobacteriaceae Enrichment Broth* to contain 0.1, 0.01, or 0.001 g or mL of the product. Incubate at 30°–35° for 24 to 48 hours. Subculture onto a plate of *Violet-Red Bile Agar* with *Glucose* and *Lactose*, and incubate at 30°–35° for 18 to 24 hours. Growth of well developed, generally red or reddish, colonies of Gram-Negative bacteria reveal the presence of enterobacteria. Determine the most probable number of microorganisms per g or per mL by reference to *Table 2*.

Table 2. The Most Probable Enterobacterial Count

Observed Presence of Enterobacteria			
Number of g of specimen per tube			
0.1	0.01	0.001	Most Probable Number of Enterobacteria per g
+	+	+	more than 100
+	+	–	fewer than 100 but more than 10
+	–	–	fewer than 10 but more than 1
–	–	–	fewer than 1

(2022) MICROBIOLOGICAL PROCEDURES FOR ABSENCE OF SPECIFIED MICROORGANISMS— NUTRITIONAL AND DIETARY SUPPLEMENTS

INTRODUCTION

Good manufacturing practices require that objectionable organisms be absent from nonsterile nutritional and dietary products. A microorganism can be considered objectionable if it represents a potential health hazard to the user who is using the product as directed, or if it is capable of growing in the product. Objectionable microorganisms are defined as contaminants that, depending on the microbial species, number of organisms, dosage form, intended use, and patient population, would adversely affect product safety. Additionally, microorganisms may be deemed objectionable if they adversely affect product stability or if they may damage the integrity of the container closure system.

This chapter describes the testing of nutritional and dietary articles for specified microorganisms, which are specified in the individual monographs or whose absence is recommended by the guidance under *Microbiological Attributes of Nonsterile Nutritional and Dietary Supplements* (2023). When objectionable microorganisms are not specified in the individual monograph, it is the manufacturers' responsibility to determine which microorganisms in their products are objectionable. It is not intended that all nonsterile nutritional and dietary articles be tested for the absence of all of the microorganisms mentioned in this chapter, nor is the testing of relevant microorganisms restricted to those presented in this chapter.

Alternative microbiological, physicochemical, and biotechnological methods, including automated methods, may be substituted for these tests, provided they have been validated as being equivalent in their suitability for determining compliance.

BUFFER AND MEDIA

General Considerations

See *Buffer Solution and Media* under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* (2021). The appropriateness of each medium for the intended purpose is to be assessed. Control sets of *Fluid Soybean–Casein Digest Medium* for *Preparatory Testing* are also used to assess the appropriateness of these media in the growth promotion of the specified microorganisms. For other media, streak agar plates to obtain isolated colonies of appropriate microorganisms, and inoculate the fluid media with the appropriate microorganisms at a final concentration of less than 100 cfu per mL. Observe the growth to establish the appropriateness of the media.

Buffer

Buffer Stock Solution and pH 7.2 Phosphate Buffer—Proceed as directed under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* (2021).

Media

FLUID SOYBEAN–CASEIN DIGEST MEDIUM

Prepare as directed under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* (2021).

MANNITOL–SALT–AGAR MEDIUM

Pancreatic Digest of Casein	5.0 g
Peptic Digest of Animal Tissue	5.0 g
Beef Extract	1.0 g
D-Mannitol	10.0 g
Sodium Chloride	75.0 g
Agar	15.0 g
Phenol Red	0.025 g
Water	1000 mL

Mix, then heat with frequent agitation, and boil for 1 minute to effect solution.
pH after sterilization: 7.4 ± 0.2 .

FLUID TETRATHIONATE MEDIUM

Pancreatic Digest of Casein	2.5 g
Peptic Digest of Animal Fat	2.5 g
Bile Salts	1.0 g
Calcium Carbonate	10.0 g
Sodium Thiosulfate	30.0 g
Water	1000 mL

Heat to boiling. Do not autoclave; use the same day. Immediately before use, add a solution prepared by dissolving 5 g of potassium iodide and 6 g of iodine in 20 mL of water. Then add 10 mL of a solution of brilliant green (1 in 1000), and mix. Do not heat after adding the brilliant green solution.

BRILLIANT GREEN–AGAR MEDIUM

Yeast Extract	3.0 g
Peptic Digest of Animal Tissue	5.0 g
Pancreatic Digest of Casein	5.0 g
Lactose	10.0 g
Sodium Chloride	5.0 g
Sucrose	10.0 g
Phenol Red	80.0 g
Agar	20.0 g
Brilliant Green	12.5 mg
Water	1000 mL

Boil for 1 minute. Sterilize just prior to use, melt, pour into Petri dishes, and allow to cool.
pH after sterilization: 6.9 ± 0.2

XYLOSE–LYSINE–DESOXYCHOLATE–AGAR MEDIUM

Xylose	3.5 g
L-Lysine	5.0 g
Lactose	7.5 g
Sucrose	7.5 g
Sodium Chloride	5.0 g
Yeast Extract	3.0 g
Phenol Red	80 mg
Agar	13.5 g
Sodium Desoxycholate (as Bile Salts)	2.5 g
Sodium Thiosulfate	6.8 g
Ferric Ammonium Citrate	800 mg
Water	1000 mL

Heat, with swirling, just to the boiling point. Do not over-heat or sterilize. Transfer at once to a water bath maintained at about 50°, and pour into Petri plates as soon as the *Medium* has cooled.

Final pH: 7.4 ± 0.2.

HEKTOEN ENTERIC AGAR MEDIUM

Protease Peptone	12.0 g
Yeast Extract	3.0 g
Lactose	12.0 g
Sucrose	2.0 g
Salicin	9.0 g
Bile Salts No. 3	9.0 g
Sodium Chloride	5.0 g
Sodium Thiosulfate	5.0 g
Ferric Ammonium Citrate	1.5 g
Acid Fuchsin	0.1 g
Bromothymol Blue	65 mg
Agar	14.0 g
Water	1000 mL

Mix, and allow to stand for 10 minutes. Heat gently, and allow to boil for a few seconds to dissolve the agar. Do not sterilize. Cool to 60°, and pour into Petri dishes.

Final pH: 7.5 ± 0.2.

TRIPLE SUGAR–IRON–AGAR MEDIUM

Pancreatic Digest of Casein	10.0 g
Pancreatic Digest of Animal Tissue	10.0 g
Lactose	10.0 g
Sucrose	10.0 g
Dextrose	1.0 g
Ferrous Ammonium Sulfate	200 mg
Sodium Chloride	5.0 g
Sodium Thiosulfate	200 mg
Agar	13.0 g
Phenol Red	25 mg
Water	1000 mL

pH after sterilization: 7.3 ± 0.2.

MACCONKEY AGAR MEDIUM

Pancreatic Digest of Gelatin	17.0 g
Pancreatic Digest of Casein	1.5 g
Peptic Digest of Animal Tissue	1.5 g
Lactose	10.0 g
Bile Salts Mixture	1.5 g
Sodium Salts Mixture	5.0 g
Agar	13.5 g
Neutral Red	30 mg
Crystal Violet	1.0 mg
Water	1000 mL

Boil for 1 minute to effect solution.
pH after sterilization: 7.1 ± 0.2.

LEVINE EOSIN–METHYLENE BLUE–AGAR MEDIUM

Pancreatic Digest of Gelatin	10.0 g
Dibasic Potassium Phosphate	2.0 g
Agar	15.0 g
Lactose	10.0 g
Eosin Y	400 mg
Methylene Blue	65 mg
Water	1000 mL

Dissolve pancreatic digest of gelatin, dibasic potassium phosphate, and agar in water, with warming, and allow to cool. Just prior to use, liquefy the gelled agar solution, and add the remaining ingredients, as solutions, in the following amounts: for each 100 mL of the liquefied agar solution, add 5 mL of lactose solution (1 in 5), 2 mL of the eosin Y solution (1 in 50), and 2 mL of methylene blue solution (1 in 300). Mix. The finished *Medium* may not be clear.

pH after sterilization: 7.1 ± 0.2.

BAIRD–PARKER AGAR MEDIUM

Pancreatic Digest of Casein	10.0 g
Beef Extract	5.0 g
Yeast Extract	1.0 g
Lithium Chloride	5.0 g
Agar	20.0 g
Glycine	12.0 g
Sodium Pyruvate	10.0 g
Water	950 mL

Heat with frequent agitation, and boil for 1 minute. Sterilize, cool to between 45° and 50°, and add 10 mL of sterile potassium tellurite solution (1 in 100) and 50 mL of egg yolk emulsion prepared as follows. Disinfect the surface of whole-shell eggs, aseptically crack the eggs, transfer intact yolks to a sterile graduated cylinder, add sterile saline TS to obtain a 3 to 7 ratio of egg yolk to saline, add to a sterile blender cup, and mix at high speed for 5 seconds. Mix all ingredients well but gently, and pour into plates.

pH after sterilization: 6.8 ± 0.2.

VOGEL–JOHNSON AGAR MEDIUM

Pancreatic Digest of Casein	10.0 g
Yeast Extract	5.0 g
Mannitol	10.0 g
Dibasic Potassium Phosphate	5.0 g
Lithium Chloride	5.0 g
Glycine	10.0 g
Agar	16.0 g
Phenol Red	25.0 mg
Water	1000 mL

Boil for 1 minute. Sterilize, cool to between 45° and 50°, and add 20 mL of sterile potassium tellurite solution (1 in 100).

pH after sterilization: 7.2 ± 0.2.

FLUID SELENITE–CYSTINE MEDIUM

Pancreatic Digest of Casein	5.0 g
Lactose	4.0 g
Sodium Phosphate	10.0 g
Sodium Acid Selenite	4.0 g
L-Cystine	10.0 g
Water	1000 mL

Mix, and heat to effect solution. Then heat in flowing stream for 15 minutes. Do not sterilize.

Final pH: 7.0 ± 0.2.

REINFORCED MEDIUM FOR CLOSTRIDIA

Beef Extract	10.0 g
Peptone	10.0 g
Yeast Extract	3.0 g
Soluble Starch	1.0 g
Glucose Monohydrate	5.0 g
Cysteine Hydrochloride	0.5 g
Sodium Chloride	5.0 g
Sodium Acetate	3.0 g
Agar	0.5 g
Water	1000 mL

Dissolve agar in water by heating to boiling, while stirring continuously. Adjust the pH if necessary, and sterilize.

pH after sterilization: 6.8 ± 0.2.

COLUMBIA AGAR

Pancreatic Digest of Casein	10.0 g
Meat Peptic Digest	5.0 g
Heart Pancreatic Digest	3.0 g
Yeast Extract	5.0 g
Cornstarch	1.0 g
Sodium Chloride	5.0 g
Agar	15.0 g
Water	1000 mL

Dissolve agar in water by heating to boiling and with continuous stirring. If necessary, adjust the pH. Sterilize, and

allow to cool to 45° to 50°. Add, when necessary, gentamicin sulfate, equivalent to about 20 mg of gentamicin base, and pour into Petri dishes.

Pre-reduction of the medium is recommended. pH after sterilization: 7.3 ± 0.2.

RAPPAPORT VASSILIADIS SALMONELLA ENRICHMENT BROTH

Soya Peptone	4.5 g
Magnesium Chloride Hexahydrate	29.0 g
Sodium Chloride	8.0 g
Dipotassium Phosphate	0.4 g
Potassium Dihydrogen Phosphate	0.6 g
Malachite Green	0.036 g
Purified Water	1000 mL

Dissolve, warming slightly. Sterilize in an autoclave using a validated cycle, at a temperature not exceeding 115°.

The pH is 5.2 ± 0.2 at 25° after heating and autoclaving.

PREPARATORY TESTING

Proceed as directed for *Preparatory Testing* under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* (2021).

For enrichment broth, selective media, and differential media use an inoculating loop to transfer the inoculum of each test organism to the plated or liquid media being tested. If a plated medium is being tested, streak the surface of plate with the loop in four directions to obtain a pattern of isolated colonies. Incubate the media, and examine the plated or liquid media for the characteristic growth of the inocula (See *Tables 1, 2, 3, and 4*).

SAMPLING

Proceed as directed for *Sampling* under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* (2021).

TEST PROCEDURES

Test Preparation—Prepare as directed for *Sampling*. Transfer to a suitable container with 100 mL of *Fluid Soybean–Casein Digest Medium (FSCD)*. Mix by shaking gently. [NOTE—On the basis of results for *Preparatory Testing*, modify the *Test Preparation* as appropriate.]

Test for Absence of *Staphylococcus aureus*

Incubate at 30° to 35° for 18 to 24 hours. Streak a loopful from *FSCD* onto the surface of one or more of the following media: *Vogel–Johnson Agar Medium (VJ Agar)*, *Mannitol–Salt–Agar Medium (MS–Agar)*, and *Baird–Parker Agar Medium (BP Agar)*. Cover the Petri plates, invert them, and incubate at 30° to 35° for 24 to 48 hours.

Examine the plates of *VJ Agar*, *MS–Agar*, and/or *BP Agar*, and interpret the results with reference to *Table 1*: if no plate contains colonies having the characteristics described, the test specimen meets the requirement for the absence of *Staphylococcus aureus*. If characteristic colonies are present, perform coagulase test as follows. Transfer representative colonies to separate tubes containing 0.5 mL of rabbit plasma, horse plasma, or any other mammalian plasma. Incubate in a water bath at 37°. Examine for coagulation after 3 hours of incubation and at suitable intervals up to

24 hours. Comparing with positive and negative controls, the absence of a coagulase reaction indicates the absence of *Staphylococcus aureus* in the tested article.

Table 1. Characteristics of *Staphylococcus aureus* on Specified Agar Media

Agar Medium	Colonial Morphology	Gram Stain
<i>Vogel–Johnson</i>	Black surrounded by yellow zone	(+), cocci
<i>Mannitol–Salt</i>	Yellow colonies with yellow zone	(+), cocci
<i>Baird–Parker</i>	Black, shiny surrounded by 2–5-mm clear zones	(+), cocci

Test for Absence of *Salmonella* Species

Incubate at 30° to 35° for 18 to 24 hours. From *FSCD*, pipet a 1-mL aliquot into 10 mL of *Rappaport Vassiliadis Salmonella Enrichment Broth*, mix, and incubate at 30° to 35° for 18 to 24 hours. Streak a loopful from both incubated media onto individual surfaces of one or more of following media: *Brilliant Green Agar Medium (BG-Agar)*, *Xylose–Lysine–Desoxycholate–Agar Medium (XLDC-Agar)*, and *Hektoen Enteric Agar Medium (HE Agar)*. Cover, invert the plates, and incubate at 30° to 35° for 24 to 48 hours. Examine the inoculated plates of *BG-Agar*, *XLDC-Agar*, and/or *HE Agar*, and interpret the results with reference to *Table 2*: if no colonies having the characteristics described are observed, the test specimen meets the requirement for the absence of *Salmonella* species. If colonies with characteristics described in *Table 2* are present, the suspect colonies are transferred to a slant of *Triple Sugar–Iron–Agar Medium (TSI)* using an inoculating wire, by first streaking the surface of the slant, and then stabbing the wire well beneath the surface. Incubate at 30° to 35° for 24 to 48 hours. If the tubes do not have red alkaline slants and yellow acid butts, with or without concomitant blackening of the butts from hydrogen sulfide production, the test specimen meets the requirement for the absence of *Salmonella* species.

Table 2. Characteristics of *Salmonella* Species on Specified Agar Media

Agar Medium	Colonial Morphology	Gram Stain
<i>Brilliant Green</i>	Small, transparent and colorless; or opaque, pink or white (often surrounded by pink to red zone)	(–), rods
<i>Xylose–Lysine–Desoxycholate</i>	Red, with or without black centers	(–), rods
<i>Hektoen Enteric</i>	Blue-green, with or without black centers	(–), rods

Test for Absence of *Escherichia coli*

Incubate at 30° to 35° for 24 to 48 hours. From *FSCD*, pipet a 1-mL aliquot into a container containing 10 mL of *MacConkey Broth*, mix, and incubate at 42° to 44° for 24 to 48 hours. Streak a loopful from both incubated media onto individual surfaces of *MacConkey Agar Medium (MC Agar)*, and incubate at 30° to 35° for 18 to 24 hours. Examine the inoculated *MC Agar* plate, and interpret the results with reference to *Table 3*: if no colonies having the characteristics described are observed, the test specimen meets the requirement for the absence of *Escherichia coli*. Suspect colo-

nies showing the characteristics described in *Table 3* are transferred individually, using an inoculating loop, to the surface of a plate with *Levine Eosin–Methylene Blue–Agar Medium (LEMB-Agar)*. If a large number of suspect colonies are to be transferred, divide the surface of each plate into quadrants, each quadrant being inoculated with a different colony. Cover the plates, invert, and incubate at 30° to 35° for 24 to 48 hours. If none of the colonies exhibit a characteristic metallic sheen under reflected light, and if none exhibit a blue-black appearance under transmitted light, the test specimen meets the requirement for the absence of *Escherichia coli*.

Table 3. Characteristics of *Escherichia coli* on MacConkey Agar Medium

Colonial Morphology	Gram Stain
Brick red, may have surrounding zone of precipitated bile	(–), rods

Test for Absence of *Clostridium* Species

Test Preparation—Prepare as directed for *Sampling*. [NOTE—On the basis of results for *Preparatory Testing*, modify the *Test Preparation* as appropriate.]

Procedure—Take two equal portions of the *Test Preparation*, heat one to 80° for 10 minutes, and cool rapidly. Transfer 10 mL of each portion to separate containers, each containing 100 mL of *Reinforced Medium for Clostridia*, and incubate under anaerobic conditions at 35° to 37° for 48 hours. After incubation, subculture each specimen on *Columbia Agar Medium* to which gentamicin has been added, and incubate under anaerobic conditions at 35° to 37° for 48 hours. Examine the plates, and interpret with reference to *Table 4*: if no growth of microorganisms is detected, the test specimen meets the requirement for the absence of *Clostridium* species.

Table 4. Characteristics of *Clostridium* Species on Specified Media

Medium	Gram Stain	Catalase
<i>Reinforced Medium for Clostridia</i>	(+), rods	
<i>Columbia Agar</i>	(+), rods	Negative

If growth occurs, subculture each distinct colony on *Columbia Agar Medium*, and separately incubate in aerobic and in anaerobic conditions at 35° to 37° for 48 hours. The occurrence of only anaerobic growth of gram-positive bacilli, giving a negative catalase reaction, indicates the presence of *Clostridium sporogenes*. To perform the catalase test, transfer discrete colonies to glass slides, and apply a drop of dilute hydrogen peroxide solution: the reaction is negative if no gas bubbles evolve. If the test specimen exhibits none of these characteristics, it meets the requirement for the absence of *Clostridium* species.

Retest

For the purpose of confirming a doubtful result by any of the procedures outlined in the foregoing tests following their application to a 10 g specimen, a retest on a 25 g specimen of the nutritional or dietary supplement may be conducted. Proceed as directed under *Procedure*, but make allowances for the larger specimen size.

(2023) MICROBIOLOGICAL ATTRIBUTES OF NONSTERILE NUTRITIONAL AND DIETARY SUPPLEMENTS

The raw materials, pharmaceutical ingredients, and active ingredients used in the manufacture of nutritional and dietary articles may range from chemically synthesized vitamins to plant extracts and animal byproducts, and these ingredients are typically not sterile. Considerable experience has accrued with these highly refined plant- and animal-derived pharmaceutical ingredients, such as microcrystalline cellulose, modified starch, lactose, and magnesium stearate, and their microbiological attributes are well established. Botanicals may be microbiologically contaminated at any point during cultivation, harvesting, processing, packing, and distribution. Major sources of microbial contamination are associated with human or animal feces used as plant manure, contaminated irrigation water and/or process water, and poor worker hygiene and sanitation practices during harvesting, sorting, processing, packaging, and transportation. Furthermore, it is essential that microbiological contamination be minimized during the manufacture of nonsterile dietary supplements. To achieve this, Good Manufacturing Practices are employed and adequate microbiological specifications are established.

Microbiological process control, control of the bioburden of raw materials, and control of the manufacturing process to minimize cross-contamination are necessary to guarantee acceptable microbial quality in the final dosage forms. Because nonaqueous or dry dosage forms do not support microbial growth because of low water activity, the microbial quality of such articles is a function of the microorganisms introduced through ingredients or during processing. In addition to considering the intended use of the product, the frequency of microbial testing for the finished nonsterile dietary supplement would be a function of the historical microbial testing database of that product, knowledge of the manufacturing processes, the susceptibility of the formulation to microbial proliferation, and the demonstrated effectiveness of programs controlling the raw materials.

FORMULATION AND PROCESS DESIGN

From a microbiological perspective, the development of the formulation of nutritional or dietary supplements includes an evaluation of raw materials and their suppliers and the contribution made to the products by each ingredient and the manufacturing processes. Characterization of these elements allows the adequacy of the manufacturing process to be demonstrated. For example, if a product is formulated with an ingredient of botanical or animal origin known to possess a high, variable, or unpredictable level of microbiological contamination, it is necessary to ensure that the microbiological monitoring identifies ingredients that have an inappropriate bioburden level and that a premanufacturing process such as drying, extraction, heat treatment, irradiation, or gaseous sterilization treatment will inactivate or remove any objectionable contaminant possibly present.

However, the selected treatment technique should not have any adverse effects. The treatment of raw materials by irradiation and ethylene oxide may cause unwanted changes affecting the safety and efficacy of the raw material. For instance, when treated by ethylene oxide, crude extracts containing alkaloids have shown reduced contents of alkaloids. Dry heat treatment has been used for inactivation as well, but it requires further evaluation because it may adversely affect stability and degradation of the raw material.

With regard to the design of the manufacturing process, appropriate consideration should be given to the microbiological effect of wet granulation manufacturing processes. Wetting of a dry powder can result in increased levels of microorganisms if the granulation is stored prior to drying. However, it is recognized that the pressure and temperature associated with compression of tablets will decrease microbial counts. Antimicrobial activity is also achieved, especially with aqueous preparations, by the addition of chemicals that have known antimicrobial properties and that are compatible with the formulation.

However, antimicrobial preservation is not a substitute for Good Manufacturing Practices. A process has to be designed to minimize the microbiological population. Operating procedures and temperatures and time limits, including holding times, are established to protect the product from microbiological contamination and growth. All processes have to be validated for their intended purposes. Moreover, in-process manufacturing and testing controls necessary for microbiological quality should be identified and implemented.

FACILITIES, EQUIPMENT, WATER, AND SANITIZATION

Facilities—The facilities, including the building and the heating, ventilation, and air-conditioning (HVAC) systems, should be designed to minimize microbiological contamination. The design of facilities used for the manufacture of supplements and their operating parameters should be documented, and the documentation should include, when appropriate, HVAC filter types, space pressure differentials, temperature, and relative humidity and air changes. Dry products processed in a dry environment do not possess a high potential for increased microbial levels. However, some control is warranted to minimize microbiological and chemical contamination. Potentially problematic areas are those that utilize *Purified Water* for wet granulation, batching liquid products, and film-coating tablets, because water encourages microbial growth.

Equipment—Equipment used for the processing of semi-solid and dry supplements should be designed to promote sanitary conditions, to be self-drying, and to be easy to clean. Dryers, ovens, wet granulation equipment, bulk tanks, and equipment for preparation of coating solutions are periodically evaluated to ensure that cleaning procedures are adequate.

Water—As one of the major components in nutritional and dietary supplement manufacturing processes, water deserves a special consideration in the microbiological control of these articles. It is a growth medium for a variety of microorganisms that present a threat to product quality, safety, preservation, and stability. Water may even act as a carrier of objectionable microorganisms. In view of this, water used in manufacturing is *Purified Water*. For the manufacture of raw materials, process water that meets specific microbiological objectives and U.S. Environmental Protection Agency National Drinking Water standards or equivalent European and Japanese standards may be used.

Cleaning and Sanitization—Detailed and specific cleaning and sanitization procedures should be evaluated, developed, and validated, with special attention given to product contact surfaces. Personnel should possess sufficient knowledge of these procedures.

SUPPLEMENT COMPONENTS

Raw materials, excipients, and active substances as components of nutritional and dietary supplements can be a primary source of microbiological contamination. Specifications should be developed and sampling plans and test procedures should be employed to guarantee the desired micro-

biological attributes of these materials. The nature and extent of microbiological testing should be based upon a knowledge of the material’s origin, its manufacturing process, its use, and historical data and experience. For instance, materials of animal or botanical origin that are not highly refined might require special, more frequent testing than synthetic products.

Since members of the family *Enterobacteriaceae* are a major component of the normal epiphytic and endophytic microflora (e.g., members of genera *Klebsiella*, *Enterobacter*, and *Erwinia*) and have been associated with the seeds, pods, roots, leaves, and stems of plants of economic importance, *Coliform* or *Enterobacteriaceae* counts will not be an appropriate general microbiological criterion for botanicals. However, when it is considered advantageous, *Coliform* or *Enterobacteriaceae* counts may be included in the individual monographs. Typically on new leaves, bacteria predominate in the microflora, while yeast and filamentous fungi succeed bacteria and become dominant late in the growing season. With dried botanicals, the bacterial population will tend to change from Gram-negative bacteria to Gram-positive spore formers and fungi. Refinement of botanicals from chopped or powdered plant material to powdered extracts using alcoholic, alkaline, acid hydro-alcoholic, or aqueous extracting materials will reduce the likelihood of vegetative microorganisms within the botanical material. The classification of botanical materials is contained in *Table 1*.

MICROBIOLOGICAL TESTING

Frequency of Sampling and Testing

Microbiological attribute sampling and testing plans vary widely. In some cases no sampling or testing is necessary; in

other cases periodic monitoring is warranted; and yet for some articles each batch requires sampling and testing. The design of the sampling and testing plans and the kind of attributes examined depend on the application and the type of the product, the potential for contamination from components and processing, the growth promotion or inhibition properties of the formulation, and the target population for the supplement. For example, a powdered botanical may have highly variable microbiological attributes so that an incoming batch would be sampled and composite testing would not be advised, while a highly refined botanical extract may not require routine microbial testing. Similarly, products with a low water activity will not be susceptible to microbial growth during their shelf life provided they are protected from elevated humidity by their containers.

Microbial Enumeration Tests

See the *Introduction* under *Microbial Enumeration Tests—Nutritional and Dietary Supplements* (2021). These tests provide meaningful information regarding the microbiological acceptability of excipients, active substances, and nonsterile supplement formulations. If the individual monograph does not specify microbial enumeration limits, the guidance provided in this chapter is used. Acceptable general limits of microbial levels for raw materials, excipients, and botanical products are shown in *Table 2*; and those for raw materials, excipients, active ingredients, and other nonsterile finished articles that are nutritional supplements but do not contain botanicals are shown in *Table 3*.

Table 1. Definitions of a Range of Botanical Materials

Botanical Preparation	Definition
Chopped or Powdered Botanicals	Hand-picked portions of the botanical (e.g., leaves, flowers, roots, tubers, etc.) that are air dried, and chopped, flaked, sectioned, ground, or pulverized to the consistency of a powder.
Botanical Extracts	Extracts are solids or semisolid preparations of a botanical that are prepared by percolation, filtration, and concentration by evaporation of the percolate. The extracting material may be alcoholic, alkaline, acid hydro-alcoholic, or aqueous in nature. Typically an extract is 4 to 10 times as strong as the original botanical. The extracts may be semisolids or dry powders termed powdered extracts.
Tinctures	Tinctures are solutions of botanical substances in alcohol obtained by extraction of the powdered, flaked, or sectioned botanical.
Infusions	Infusions are solutions of botanical principles obtained by soaking the powdered botanical in hot or cold water for a specified time and straining. Typically infusions are 5% in strength.
Decoctions	Decoctions are solutions of botanicals prepared by boiling the material in water for at least 15 minutes and straining. Typically decoctions are 5% in strength.
Fluidextracts	A fluidextract is an alcoholic liquid extract made by percolation of a botanical so that 1 mL of the fluidextract represents 1 g of the botanical.
Botanicals to be treated with boiling water before use	Dried botanicals to which boiling water is added immediately prior to consumption.

Table 2. Recommended Microbial Limits for Botanical Ingredients and Products

Material	Recommended Microbial Limit Requirements (cfu/g or mL)
Dried or Powdered Botanicals	Total Aerobic Microbial Count NMT 10 ⁵
	Total Combined Yeast & Mold Count NMT 10 ³
	Bile-tolerant Gram-negative Bacteria NMT 10 ³
	Absence of <i>Salmonella</i> spp. & <i>E. coli</i> in 10 g

Table 2. Recommended Microbial Limits for Botanical Ingredients and Products (Continued)

Material	Recommended Microbial Limit Requirements (cfu/g or mL)
Powdered Botanical Extracts	Total Aerobic Microbial Count NMT 10 ⁴
	Total Combined Yeast & Mold Count NMT 10 ³
	Absence of <i>Salmonella</i> spp. & <i>E. coli</i> in 10 g
Tinctures	Total Aerobic Microbial Count NMT 10 ⁴
	Total Combined Yeast & Mold Count NMT 10 ³
Fluidextracts	Total Aerobic Microbial Count NMT 10 ⁴
	Total Combined Yeast & Mold Count NMT 10 ³
Infusions/Decoctions	Total Aerobic Microbial Count NMT 10 ²
	Total Combined Yeast & Mold Count NMT 10
Nutritional Supplements with Botanicals	Total Aerobic Microbial Count NMT 10 ⁴
	Total Combined Yeast & Mold Count NMT 10 ³
	Absence of <i>Salmonella</i> spp. & <i>E. coli</i> in 10 g
Botanicals to be treated with boiling water before use	Total Aerobic Microbial Count NMT 10 ⁵
	Total Combined Yeast & Mold Count NMT 10 ³
	Absence of <i>E. coli</i> in 10 g

Table 3. Recommended Microbial Limits for Dietary Supplement Ingredients and Products

Material	Recommended Microbial Limit Requirements (cfu/g or mL)
Other raw materials and dietary supplement ingredients	Total Aerobic Microbial Count NMT 10 ³
	Total Combined Yeast & Mold Count NMT 10 ²
	Absence of <i>E. coli</i> in 10 g
Nutritional supplements with synthetic or highly refined ingredients	Total Aerobic Microbial Count NMT 10 ³
	Total Combined Yeast & Mold Count NMT 10 ²
	Absence of <i>E. coli</i> in 10 g

Absence of Objectionable Microorganisms

See Introduction under Microbiological Procedures for Absence of Specified Microorganisms—Nutritional and Dietary Supplements (2022). Absence of one or more species of objectionable microorganisms is required in some individual monographs.

Test for Aflatoxins—Dietary and nutritional articles containing botanical products with a history of mycotoxin contamination are also typically tested for aflatoxins, especially if the material is obtained from roots or rhizomes. See Articles of Botanical Origin (561) for the details of a test for aflatoxins. Where necessary, this test is included in the individual monograph.

Solid Oral Dosage Forms—Among all dosage forms, solid oral dosage forms present the lowest microbiological risk because of their method of manufacture, low water activity, and route of administration. When justified, reduced microbiological testing may be appropriate.

Other Concerns—The presence of some microorganisms in articles can be an indicator of processes that are not under microbiological control. For example, Purified Water used at some stage of the manufacture of these products might contain a typical flora of Gram-negative microorganisms. As with pharmaceutical products, inadequate processing of water and poor maintenance of water systems may result in the contamination of processed formulations by Gram-negative microorganisms.

(2030) SUPPLEMENTAL INFORMATION FOR ARTICLES OF BOTANICAL ORIGIN

This general chapter provides information about several aspects of botanical articles not covered in USP standards monographs. Although the standards in the monographs address the quality issues associated with botanical plant materials, extracts, and preparations of Pharmacopeial articles, there is a need to develop appropriate information to optimize the pre-harvest conditions for appropriate growth and the post-harvest handling to achieve consistent quality with minimum variations in the composition of chemical constituents.

PROTOCOL CONTENTS

- Black Cohosh (*Actaea racemosa* L.)
- Ginger (*Zingiber officinale* Roscoe)
- Valerian (*Valeriana officinalis* L.)
- Elm (*Ulmus rubra* Muhlenberg)

GENERAL GUIDANCES

It is recommended that, at a minimum, growers and others involved in the handling and distribution of botanical products should become familiar with and follow the WHO Guidelines for Good Agricultural and Collection Practices (GACP) for Medicinal Plants (found at <http://www.who.int/medicinedocs/collect/edweb/pdf/s4928e/s4928e.pdf>).

Commercial trade in natural products occurs in a global market. Material of domestic origin must be produced in

compliance with all federal laws of the United States. Material of foreign origin, imported into the U.S., must be produced and transported in compliance with the laws of the U.S., the country of origin, and relevant international treaties. These include, but may not be limited to, the following:

1. The Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) is an international agreement between governments. Its aim is to ensure that international trade in specimens of wild animals and plants does not threaten their survival. Information about CITES is available at <http://www.cites.org>.
2. The Convention on Biological Diversity (CBD) establishes three main goals: the conservation of biological diversity, the sustainable use of its components, and the fair and equitable sharing of the benefits from the use of genetic resources. Each country that has ratified and is a party to the Convention is responsible for implementation by means of national enabling legislation that can differ from country to country.
3. The Endangered Species Act (ESA) was originally adopted in 1973. The ESA is a law that aims to protect species of fish, wildlife, and plants believed to be threatened with extinction. The ESA is administered primarily by the U.S. Fish and Wildlife Service. Full text of the act is available at: <http://epw.senate.gov/esa73.pdf>.

Provided below is additional information not covered in the compendial specifications: compendial history; sources; collection and cultivation, including common adulterants; and drying, storing, and shipping. This information is provided to complement the standards for quality control in the monographs for botanical articles.

Compendial History—The focus in this section is on historical compendial use that has strong validity, with only brief reference to anecdotal use. This is important information because traditional use is one of the elements taken into consideration to support the safety and the presumptions of benefits of botanical dietary supplements.

Sources—Included here is the point of origin of the botanical; it also encompasses cultivation (defined as agricultural growing) and wildcrafting (defined as collected in the wild), along with a listing of the primary geographical (native) areas of production.

Collection and Cultivation—This section discusses wildcrafting, the conservation of restricted and rare species, and the trend to cultivation as an ecological alternative; such optimal harvesting and collection practices serve to preserve the integrity of species and botanical products. It is divided into three subsections:

1. Collection (conservation and ecology)
2. Cultivation Practices
3. Optimal Times for Harvest

Post-Harvest Handling (Optimal Handling and Processing Practices, Drying, Storage, and Shipping)—Important factors regarding storage of herbal products and how they should be maintained include the following.

1. **Light:** Protection from light is important for botanical articles. Light accelerates numerous chemical processes that may lead to degradation or changes in the constituents of the articles.
2. **Temperature:** Storage temperatures in this *Pharmacopeia* are defined in the *General Notices*. Excessive heat may affect the content of volatile constituents (essential oils) and accelerate degradation processes. However, heat treatments are sometimes useful in the maintenance of the article's quality and can be used in drying, reducing microbial load, and inhibiting certain enzymes. Heat application during these processes must be carefully controlled to achieve the desired balance between degradation and quality conservation.

3. **Humidity:** Moisture in the articles may allow certain enzymes such as glycosidases to become active, hence degrading constituents. High humidity also increases the danger of microbial proliferation. As a rule, it is advisable to store botanical articles below 60% relative humidity. Although controlled humidity and temperature warehouses are now required in many good manufacturing practices for natural products, much of the world still lacks access to these facilities.
4. **Degree of Comminution:** The degree of comminution plays a role in determining the stability of the botanical articles during storage. The increased surface area in fine powders allows oxidation and other degradation processes to occur more extensively and rapidly than in the case of a whole article. Plants containing tannins, bitter substances, and essential oils are particularly sensitive to the degree of comminution. In general, dried crude botanicals should be stored in a minimally processed form.
5. **Containers:** Appropriate containers are defined in this *Pharmacopeia* in the *General Notices*.

Constituents—Where known, the substances mainly responsible for the activity of the product are listed, along with other compounds contained in the plant.

SUPPLEMENTAL INFORMATION AND GENERAL GUIDANCE PROTOCOLS

Black Cohosh *Actaea racemosa* L. [*Cimicifuga racemosa* (L.) Nutt.] (Fam. Ranunculaceae)

Botanical Identification—*Actaea racemosa* L. Herbaceous perennial from rhizome.

Stem: Erect, solitary, to 2.5 m tall, glabrous.

Leaves: Basal and cauline, alternate, 2–4-ternately compound, petioles 15 to 60 cm long, bases clasping stem; leaflets 20 to 70; terminal leaflet of central division 3-lobed, 6 to 15 cm long, 6 to 16.5 cm wide, with 3 prominent veins arising from base; subterminal leaflets with blades ovate-lanceolate to obovate, 4 to 12 cm long and 3 to 8 cm wide; margins toothed to deeply incised; green above, paler below; glabrous or rarely pubescent along veins of undersurface.

Inflorescence: Terminal panicle of 4 to 9 slender branches, each 7 to 60 cm long, pubescent; 1 bract subtending each pedicel.

Flowers: Perfect, radially symmetric; sepals 4, greenish-white, caducous; petals 0; staminodes (1–) 4 (–8), petaloid, cream-colored, 2 to 3 mm long, clawed, apex bifid; stamens 55 to 110; pistils 1 (–3), glabrous to pubescent, ovary superior, style short, stigma 0.5 mm wide.

Fruit: Many-seeded follicle, 5 to 10 mm long, ovoid, laterally compressed with curved, stout beak (persistent style), pubescent; seeds hemispheric, brown, scales lacking.

Chromosome number: $n = 8$.

There are currently two varieties of *A. racemosa* recognized on the basis of differences in leaf morphology: var. *racemosa* and var. *dissecta*. The former variety has triternate-pinnate leaves with serrate margins, while the latter has quadraternate-pinnate leaves that are deeply incised with serrate lobes. Variety *dissecta* is only known from very few herbarium specimens, all of which were collected well over 100 years ago, making this taxon of uncertain taxonomic significance.

Compendial History—Black cohosh appeared on the secondary list of substances in the first *United States Pharmacopeia* (USP) of 1820, where it was listed as an anti-inflammatory and antispasmodic. It soon rose to the primary list in 1830, a position it held until the 10th decennial revision of

1920. Black cohosh appeared in the first edition of the *United States Dispensatory (USD)* in 1833 and remained through 1955 for a total of 122 years. Carrying forward the traditional Native American use of black cohosh for women's ailments and Barton's use for throat complaints, current therapeutics finds the plant used in a number of preparations for coughs and for gynecological disorders. In 2001, both the rhizome and the dry rhizome extract of black cohosh were proposed once again for inclusion in the *United States Pharmacopeia–National Formulary (USP–NF)*. (See revised proposal on page 1455 of *PF 28(5)* [Sept.–Oct. 2002].) The monograph became official in the *Second Supplement to USP 30–NF 25*.

Constituents—Major constituents of black cohosh are triterpene glycosides principally as beta-xylopyranosides and alpha-arabinopyranosides. The aglycones are mostly derived from acteol and cimigenol. The nomenclature of these compounds is quite confusing in the literature, with different names often given to the same compounds. A cyclopropane ring is a common feature of these compounds, which are structurally related to cycloartenol. The isoflavone formononetin has been reported in some publications; however, recent evidence indicates its absence in the roots and rhizomes of *Actaea racemosa*. Other constituents include tannins, resin, fatty acids, starch, sugars, and aromatic acids including ferulic acid, isoferulic acid, caffeic acid, and salicylic acid.

Sources and Distribution—

Sources—Black cohosh can be found in moist deciduous forests, ravines, moist meadows, creek margins, and mountainous terrain. Black cohosh flowers from June to September and is native to eastern North America from Ontario south to Georgia and west to Missouri. The entire supply of black cohosh comes from the United States. The major producers of black cohosh are Kentucky and Tennessee, with additional supplies coming from Georgia, Michigan, North Carolina, Ohio, South Carolina, Virginia, West Virginia, and Wisconsin. Although there are reports of black cohosh being grown in China and India for export, the true identity of the cultivated material has not been verified and may well be an Asian species of *Actaea* such as *A. cimicifuga* (syn. *Cimicifuga foetida*). The vast majority of the commercial black cohosh is wild harvested. Concern over the conservation of black cohosh due to increasing demand makes this species a good candidate for cultivation.

Distribution—North America (Ontario; Georgia, Kentucky, Michigan, Missouri, North Carolina, Ohio, South Carolina, Tennessee, Virginia, West Virginia, and Wisconsin); China; and India.

Collection and Cultivation—

Collection (Conservation and Ecology)—Traditionally, black cohosh has been harvested after plants become reproductive, which occurs anywhere from 2 to 8 years of age in cultivated plants, depending on growing techniques (see *Cultivation Practices*). A portion of the rhizome with a visible bud on it should be left in the ground to resprout the following year. There is no published information on the relationship between the constituent profile of the rhizome and its age, growing conditions, or place of origin, although such studies are underway. The impact of harvest on wild populations of black cohosh is currently unknown, and sources differ in their opinion about it. Whereas some maintain that current levels of harvest threaten the viability of wild populations, others feel that sustainable harvesting is possible at current levels of demand. A study of sustainable harvest limits is currently underway. The regulatory status regarding the trade of black cohosh is under review by CITES. Refraining from harvesting plants until after they have set seed and leaving a portion of the rhizome in the ground to resprout are key components to sustainable harvesting.

Cultivation Practices—Black cohosh is grown from rhizome cuttings or seeds and requires some shading, depending on

altitude and other environmental conditions. If grown from rhizome cuttings, a plant takes 2 to 3 years to become reproductive; grown from seed sown in the greenhouse and then planted, takes 4 to 6 years; direct-seeded may take from 6 to 8 years. Preliminary work indicates that black cohosh can be propagated successfully using in vitro techniques.

Optimal Times for Harvest—Rhizomes and roots should be harvested in autumn when the plant is dormant. At that time the underground portions of the plant have lower moisture content than in other seasons. Fall harvesting also allows plants to produce mature seeds before being uprooted.

Post-Harvest Handling—

Optimal Handling and Processing Practices—Rhizomes with roots may be processed fresh or dried. They should be thoroughly washed directly after harvest and then laid out to dry. Freshly harvested roots should be solid but not woody.

Drying—Rhizomes with roots are cut and air-dried at 35° to 45°. They are fully dried when they are brittle and snap easily and when no moisture is evident in cross section, either visibly or to the touch.

Storage—Follow general guidelines for storage by packing in airtight containers protected from light, heat, moisture, and insect infestation.

Adulterants and Contaminants—Other species of *Actaea*, especially yellow cohosh (*A. podocarpa* syn. *Cimicifuga americana*), have commonly been mixed with *A. racemosa* because of similarity in aboveground appearance and common growing habitat between species. The two species can be distinguished by differences in their freshly harvested underground parts: the fresh rhizome of *A. podocarpa* has a distinct yellowish hue, whereas that of *A. racemosa* is black. The rhizomes of both species are far more difficult to tell apart when dry because *A. podocarpa* darkens upon drying. The underground portions of baneberry (*Actaea pachypoda* and *A. rubra*) occur as occasional adulterants of black cohosh supplies. Fruiting plants of baneberry may be distinguished from black cohosh by their fleshy white or red poisonous berries, which contrast with the dry follicles of black cohosh. No information was available on how to distinguish the underground portions of black cohosh and baneberry from each other. According to one herb dealer, the roots of baneberry are smaller than those of black cohosh, and therefore are not often harvested by wildcrafters. In the Pacific Northwest, *Actaea elata* (syn. *Cimicifuga elata*) is collected for medicinal use.

Ginger *Zingiber officinale* Roscoe (Fam. Zingiberaceae)

Botanical Identification—*Zingiber officinale* Roscoe. Herbaceous perennial from tuberous rhizome, aromatic because of the presence of volatile oils.

Stem: Erect, unbranched pseudostem formed by the tight overlap of sheathing leaf bases; 0.9 to 1.5 m tall.

Leaf: Simple, alternate and two-ranked, sessile or petioles short with bases sheathing the stem and a ligule where the leaf base meets the stem; blade linear to narrowly lanceolate, 15 to 25 cm long, 1.5 to 3 cm wide; margin entire; glabrous to pubescent.

Inflorescence: Terminal spike, 3.5 to 8 cm long, 1.5 to 2 cm wide, with conspicuous spirally arranged primary bracts; usually borne on specialized leafless stems.

Flower: Perfect, bilaterally symmetric; calyx tubular with 3 lobes; corolla tube 2 to 2.5 cm long with lanceolate apical lobes, 1.5 to 2 cm long, 2 to 3.5 mm wide, greenish yellow; stamen 1, anther cream-colored with dark purple, elongated connective grasping upper part of style; staminodes 4, petaloid, 2 fused into an erect, ovate-oblong lip that is dull pur-

ple with cream mottling; ovary inferior; style 1, slender, exerted beyond connective.

Fruit: Loculicidal capsule; seeds shiny black with a white aril.

Chromosome number: n = 11.

There are several different varieties and forms of ginger. The varying morphological characteristics of these are displayed in *Table 1*.

Compendial History—Ginger was official in the *United States Pharmacopoeia* from the first edition of 1820 through the fourteenth revision of 1950, often appearing in multiple preparations. It also appeared in all editions of the *United States Dispensatory* from 1833 through the final edition of 1973, where it was described as “a stimulant and carminative that has been used for treatment of dyspepsia and flatulent colic”.

Constituents—The essential oils and the pungent principles make up some of the major components of the rhizome of ginger: 4.0% to 10.0% of the rhizome consists of an oleoresin composed of nonvolatile, pungent principles (phenols such as gingerols and their related dehydration products, shogaols); nonpungent fats and their waxes. The essential oil (1% to 3%) contains sesquiterpenes and monoterpenes, mainly geranial and nerals. Generally, but not always, sesquiterpenes predominate (30% to 70%), such as zingiberene, sesquiphellandrene, and beta-bisabolene, which decompose on drying and storage. The nonvolatile pungent principles include the phenylalkanones, the gingerols, and the phenylalkanonols, shogaols with varying chain lengths.

Sources and Distribution—

Sources—Ginger is cultivated in most tropical and subtropical countries to greater or lesser degrees. The world production is estimated to be 100,000 tons. China and India are reported to be the primary areas of production. Approximately 5000 tons of ginger are imported into the United States. An estimated 80% of this comes from China. In China, Sichuan and Guizhou provinces reportedly produce the largest quantities and highest quality. It is also produced in Guangdong, Hubei, Shandong, Shanxi, and Zhejiang provinces. Most of the dried ginger from China available in the United States has had the cortex scraped or rubbed off before it is dried. This gives it a whitish appearance. The freshly dug root is soaked overnight in water, scraped with a knife to remove the outer cortex, and then sun-dried. It has been reported that high arsenic levels in

the soil of Changning County of Hunan Province, China, has negatively affected ginger yields.

In India, ginger is grown on a large scale in the warm, moist regions of Madras and Cochin, and to a lesser extent in Bengal and the Punjab. Varieties grown in Bengal are reportedly the highest quality material in India. Other areas of production include Africa (Nigeria and Sierra Leone), Australia, the East Indies, Fiji, Hawaii, and Jamaica. The morphological characteristics of ginger cultivated in these different areas are outlined in *Table 1*.

In older literature, Jamaican ginger is reported to be the highest quality and the most aromatic, though supplies are limited.

Distribution—Most tropical and subtropical countries, such as Australia, China (Guangdong, Guizhou, Hubei, Shandong, Shanxi, Sichuan, and Zhejiang provinces), India (Bengal, Cochin, Malabar), the East Indies, Fiji, Jamaica, Japan, Nigeria, and Sierra Leone. Hawaii in the United States.

Collection and Cultivation—

Collection (Conservation and Ecology)—When the stems wither and are white, the rhizomes are ready for collection. Usually ginger is harvested after 6 months of growth at the earliest, and sometimes not until as late as 20 months; or to obtain larger roots, it is harvested in January or February of the second year of growth. In tropical and subtropical areas, roots are harvested as early as 4 months of growth, because they tend to become fibrous and tough as they get older. As ginger matures, it becomes more fibrous and stronger in flavor. Ginger harvest can be described in three stages:

1. Ginger that has been harvested early is known as green ginger and is traded as fresh ginger. It is succulent and tender, mellow, and mildly aromatic with a floral or lemony aroma and mild flavor.
2. Ginger harvested a few months later is more fibrous and drier and is collected for drying and may be sold as a full-flavored, pungent dried whole ginger.
3. The last harvest is usually around 9 months and yields the strongest ginger, which is quite dry and also richest in pungent components. This ginger is dried and then ground into powder.

Cultivation Practices—Ginger is a perennial herb that grows well at subtropical temperatures where the rainfall is at least 1.98 meters per year. The plant is sterile and is grown by vegetative means. Selected pieces of rhizome (“seed pieces” or “setts”), each bearing a bud, are planted in holes or trenches. Ideally the soil should be well-drained,

Table 1. Morphological and Key Characteristics of Ginger from Different Areas of Production

Source	Form	Aroma	Color (External)
Africa	Flat surfaces, mostly peeled, starchy and fibrous; 9 cm long, 1.5 cm wide	Poor quality is recognized by its camphoraceous aroma	Uncut surface dark grayish-brown; cut surface brownish-black
Australia		Citrus-like	Buff
Bengal	Flat surfaces, scraped		Gray-brown
China	Short stumpy lobes, unscraped, mostly sliced	Strong, floral to citrus	Pale brown
Cochin	Lateral surfaces lacking cork	Strong, floral to citrus	Cream color with numerous black resin dots
Jamaica (unbleached)	Up to 12 cm long, 1 cm wide; surfaces completely peeled; starchy and fibrous thin cortex	Delicate, citrus-like	All surfaces yellow-brown
Japan	Up to 7 cm long, 12 mm wide; flat surfaces usually completely peeled; starchy and fibrous thick cortex	Bergamot-like	Externally gray-white to light grayish-brown, often with white powder from being coated with lime
Malabar (Cochin and Calcutta)	Cork layer completely removed, mostly treated with chalk	Citrus-like	Almost white
Nigeria	Smaller in size than other varieties, rather less deeply scraped	Delicate	Somewhat darker than other varieties

rich clay loam. The growing conditions resemble those of potato cultivation. Mulching or manuring is necessary because the plant rapidly exhausts the soil of nutrients.

Ginger is susceptible to waterlogging and root rot. Preventive methods include using only the cleanest ginger for planting and washing it with fungicide before planting. A study growing ginger hydroponically yielded up to 125 tons per hectare in 6 to 7 months compared to 35 tons per hectare when grown in soil.

Optimal Times for Harvest: typically in December or January.

Post-Harvest Handling—

Optimal Handling and Processing Practices—After harvesting, the rhizome is cleaned and stripped of its stems and roots. Each area processes its ginger differently after harvest. This results in the different quality and commercial grades available on the market. Green ginger consists of the rhizomes sent to market without drying. Unscraped or partially scraped varieties are traded as coated or black ginger. These roots have been scalded with boiling water and dried quickly. When dry, black ginger breaks with a horny, blackish, somewhat diaphanous fracture, due to the pasty condition of the starch. White ginger is bleached, usually by rubbing with chalk or lime, to lighten its color and to prevent insect infestation. Preserved ginger consists of soft, yellowish-brown pieces obtained by steeping the fresh ginger in hot syrup and carefully bottling. It is soft, brown-yellow and translucent. When baked, ginger loses its pungency and acquires a bitter taste.

Drying—In general, after harvest, the fresh roots are washed, and the whole dark outer skin, consisting of cork and a little underlying parenchyma, is scraped away. Scraping speeds up the drying time of the crude drug. However, excessive scraping can result in lower concentrations of essential oil that is lost with the discarded epidermal tissue. After scraping, the rhizomes are then laid out on clean floors and dried in the sun for 7 to 10 days. During this time they are occasionally turned and are piled up every night. If the fresh rhizomes are too fleshy or moist, drying will take longer and the product will end up looking shriveled. To obtain a whiter product, the ginger is moistened after 5 or 6 days and dried for another 2 days, at which time it is ready for export. Dried ginger is more pungent and stronger in taste than fresh ginger.

Storage—Store in a tightly closed container, protected from light and moisture, in a cool area. A study was done on ginger harvested after 8, 9.5, 11, or 12 months. Samples were stored at 10° to 15° and 45% to 55% relative humidity or 25° to 30° and 75% relative humidity for 0, 4, or 8 weeks. Oil and oleoresin yields increased with the age of the ginger. Room temperature storage had adverse effects, but refrigerated storage for up to 4 weeks had no effect on quality. When stored for extended periods of time, ground ginger loses its pungency.

Adulterants—Because ginger is so characteristic, unintentional adulterants are rare. However, in East Asia sometimes the much larger *Zedoary cassumer* and *Zedoary zerumbet*, along with *Alpinia allughas*, are used and found in European commerce. They are easy to distinguish because of their characteristic aromas. Occasionally, Chinese sugar-candied “ginger” is prepared from *Alpinia galangal*.

In older literature, other herbs have reportedly been used as adulterants. These include various species of *Curcuma*, *Capsicum*, and Grains of Paradise (*Amomum melegueta*) added to exhausted material in order to enhance color and pungency.

Ginger powder is sometimes adulterated with plant starches such as those from wheat middlings, potatoes, corn, barley, rice, legumes, acorns, flaxseed meal, mannihot, oil cakes from linseed, rapeseed, mustard, almond meal, palm kernel or olives, hazelnut shells, and mineral additives.

These may be easily identified microscopically. The extent of this type of adulteration in trade is unknown.

Exhausted material should be considered an adulterant.

Valerian *Valeriana officinalis* L. (Fam. Valerianaceae)

Botanical Identification—*Valeriana officinalis* L. Herbaceous perennial, rhizomatous.

Stem: Solitary, hollow, 15 to 150 cm.

Leaf: Basal and cauline, opposite, oddly once pinnately lobed, lobes 11 to 21 lanceolate, entire or dentate, basal leaves petiolate, cauline leaves subsessile to clasping.

Inflorescence: Compound cyme, terminal or axillary, many pale pink to white, strongly scented flowers.

Flower: Calyx 5-lobed, lobes inconspicuous in flower, becoming elongate and pappus-like in fruit, corolla funnel-form, slightly saccate at the base, 5-lobed, tube 4 mm, lobes 1 mm, stamens 3, filaments attached to corolla tube alternate to corolla lobes, ovary inferior, trilobulate, uniovulate, only 1 locule fertile, stigma tripartite.

Fruit: Achene crowned by persistent calyx, lanceolate-oblong, 4.5 to 5 mm, hairy or glabrous. Populations of *V. officinalis* range in ploidy level from diploid to tetraploid or octaploid. British *V. officinalis* is usually octaploid, and central European supplies are tetraploid.

There are three subspecies of *V. officinalis*: ssp. *officinalis*, ssp. *collina* (Wallr.) Nyman, and ssp. *sambucifolia* (Mikan fil.) Celak. All three of these subspecies, as well as the other European species of valerian, *V. repens* Host, have been considered acceptable source material for medicinal preparations.

Macroscopic Identification—Various chemotypes will have slightly different characteristics. When dried, the whole rhizome is up to 50 mm long and up to 30 mm in diameter, obconical to cylindrical, with an elongated or compressed base. It has a yellowish-brown to dark brown exterior with a circular stem and leaf scars. The rhizome contains numerous thick, light to dark brown rootlets that are located around a thin ligneous cord. The root is longitudinally wrinkled, approximately 100 mm long and 1 to 3 mm in diameter, almost cylindrical, and almost the same color as the rhizome. In longitudinal section, the pith exhibits a central cavity transversely by septa. The stolons are 20 to 50 mm long, pale yellowish grey with prominent nodes separated by longitudinally striated internodes. It is commonly sliced in half for ease of cleaning. The rootlets, which contain the majority of the essential oil, are brittle and break in short, horny fractures and are whitish or yellowish internally. Aroma: when dried properly, *V. officinalis* L., s.l. has only a very faint characteristic, valeric acid-like aroma that becomes stronger as it ages. Improperly dried or old material possesses a strong and characteristic odor due to the enzymatic hydrolysis of esters of the valepotriates (isovaleric acid and hydroxyvaleric acid). Taste: mildly sweet and camphoraceous with a slightly bitter and spicy aftertaste.

Compendial History—Valerian was official in the *United States Pharmacopoeia* from the first edition of 1820 through the eleventh revision of 1930, often appearing in multiple preparations. At its peak from 1850 through 1880 it appeared six to seven times in different preparations. Valerian is among the top 30 most listed botanicals in the history of the *USP*. The root of valerian has been used as a sedative and spasmolytic in Europe since the 16th century.

Constituents—Major constituents of valerian have been identified as sesquiterpenes of volatile oils and iridoids (epoxy-triesters) known as valepotriates. The total content of volatile oil varies widely within a single species and between different species. European *Valeriana officinalis* L. usually contains 0.1% to 2.8% volatile oil. The oil consists of mixtures of monoterpene and sesquiterpene derivatives. The amount of valepotriates present also varies widely between species

and genera and even within a species, generally ranging from 0.5% to 1.2%. Valepotriates are particularly unstable; they decompose easily under the effect of moisture, temperatures above 40°, or acidity (pH <3).

Valerian also contains small amounts of aliphatic acids, alkaloids, amino acids, phenolic acids, flavonoids, free fatty acids, sugars, and salts. Valerian constituents that have possible sedative effects include acetoxyvalerenic acid, 1-acevaltrate, baldrinal, didrovaltrate, hydroxyvalerenic acid, kessane derivatives, valeranone, valerenal, valerenic acid, and valtrate.

Sources and Distribution—

Sources—Valerian is found in damp or dry meadows, scrub, or woods in most of Europe, although rare in the south, and it is cultivated and naturalized in North America. Valerian is cultivated in Belgium, Britain, Eastern Europe, France, Germany, Japan, the Netherlands, North America, and Russia. The majority of standardized extract products and crude cut and sifted material on the domestic market are prepared from European supplies. A large number of liquid extracts are prepared from domestically cultivated material. Many species other than *V. officinalis* are reported to be traded as medicinal valerian. These include *V. edulis* Nutt. ex Torr. & A. Gray, *V. corneana* Briq. k, *V. stubendorfi* Kreyer ex Kom., *V. amurensis* P. Smirn. ex Kom., *V. hardwickii* Wall., *V. exaltata* Mikan, and *V. wallichii* DC. syn. *V. jatamansi* Jones.* The most frequently used North American species include *V. sitchensis* Bong and *V. edulis* Nutt.* = *V. edulis* Nutt. ex Torr. & Gray ssp. *procera*. Other species reported to be used locally include *V. arizonica* Gray, *V. capitata* Pall ex Link., *V. dioica* L., and *V. scouleri* Rydb. Detailed chemical analyses of most American species are lacking. A limited number of assays of material cultivated in the Pacific Northwest show varying levels of essential oil ranging from 0.4% to 1.3%. Valerenic acid and valepotriates have been found to be present in fresh and dry samples of *V. sitchensis* Bong. *V. sitchensis* Bong exhibits a strong pungency when fresh. High quality material is reported to contain from 1.0% to 1.5% essential oil, ≥30% extractable matter, and ≥0.5% valerenic acid.

Distribution—Europe (Belgium, Britain, Eastern Europe, France, Germany, the Netherlands), Japan, North America, and Russia.

Collection and Cultivation—

Collection (Conservation and Ecology)—The majority of valerian in trade comes from cultivated material. Harvest times will vary geographically. The composition of the essential oil varies greatly among different populations of the same subspecies and even between the same population of plants from year to year. Essential oil content also varies with genotypes, harvest times, growing conditions, age of root, drying techniques, and method of analysis. It has been reported that valerian harvested in higher elevations, grown in dryer regions, or cultivated in phosphate-rich soil yields relatively high levels of essential oil.

Older literature reports that valerian should be harvested in the fall, between August and September, preferably in the second year of growth. Analyses of material cultivated in the Netherlands report that the majority of constituents, including the essential oil and valerenic acid, were highest in roots harvested in the first year of growth, with essential oil being highest in September and November (1.2% to 2.1%). The next highest level of essential oil was reported for material harvested in March (0.9% to 1.6%). Valerenic acid and its derivatives were found to be highest in February and March (0.7% to 0.9%), followed by material harvested in September (0.5% to 0.7%) and then in January (0.3% to 0.4%). From a commercial standpoint, it is more cost effective to harvest the roots in the same year the plants are sown than in the second year.

**V. wallichii* DC. and *V. edulis* Nutt. reportedly are lacking in valerenic acid and its derivatives.

Cultivation Practices—Sowing seeds has been reported to be preferred over planting of seedlings. Best results were achieved by flat field planting at row spacings of 50 cm and a seed rate of 3 kg per hectare. Cutting off the flowering tops before the plant has set seed causes the rhizome to develop more fully.

Optimal Times for Harvest—Wagner reports that harvest should take place in the morning during relatively cool weather, a general recommendation for roots rich in essential oils.

Post-Harvest Handling—

Optimal Handling and Processing Practices—The essential oil is located in the hypodermis of the rhizome in large thin-walled cells. Therefore, care must be taken not to damage these cells during handling. Excess washing of the roots can result in a significant reduction of extractive matter. Because of the sensitivity of volatile oils to heat, it is necessary to minimize the amount of time generated in the grinding or powdering process by doing small lots at a time, with frequent interruptions in run times, or by using a cryogenic grinder.

Drying—For maximum preservation of the essential oils, valerian should be dried at 40° with a flow rate of 0.05 kg per sec per m². Alternatively, drying at 20° for approximately 10 days, shade drying at approximately 45°, low temperature vacuum-drying, and freeze-drying are also reported to be appropriate drying techniques.

Careless or prolonged drying produces a darker color in the roots and results in the hydrolysis of the isovalerianic esters and the liberation of isovaleric and hydroxyisovaleric acid. This produces the characteristic valerianic aroma. Properly dried valerian will produce this same aroma over time.

Storage—Store in closed containers protected from light, air, and moisture. Hydroxyvalerenic acid, a decomposition product of acetoxyvalerenic acid, is formed when the herb is stored at too high humidity.

Improper storage conditions can cause significant deterioration of the material. Although the essential oil is relatively stable, it can evaporate with excessive exposure to air. The essential oil can degrade quickly in powdered material. In powdered root, the essential oil content can decrease by 50% within 6 months.

Valepotriates are sensitive to humidity, temperatures above 40°, and acid media (pH <3) and are generally not detected in commercial products after 60 days.

Adulterants—Other species of valerian: An unidentified *Apiaceae* species may be found in valerian trade. Adulteration of valerian in the American market is not common. Many species other than *V. officinalis* are reported to be traded as medicinal valerian. These include *V. edulis* Nutt. ex Torr. & A. Gray, *V. coreana* Briq. k, *V. stubendorfi* Kreyer ex Kom., *V. amurensis* P. Smirn. ex Kom., *V. hardwickii* Wall., *V. exaltata* Mikan, and *V. wallichii* DC. syn. *V. jatamansi* Jones.

Elm *Ulmus rubra* Muhlenberg [*Ulmus fulva* Michaux] (Fam. Ulmaceae)

Botanical Identification—*Ulmus rubra* Muhlenberg; tree to 35 m high, with spreading branches and open flat crown; preparations derived from inner bark. *U. rubra* appears to be more closely related to the introduced Asian species *U. pumila* L. than to other native American species of *Ulmus*; where the two co-occur, interbreeding is common.

Trunk: 18 to 35 m high, to 1 m in diameter; the trunk rises free of branches until about 5 to 6 m.

Branches: Erect, spreading; young twigs are scabrous-pubescent.

Bark: Dark brown to reddish-brown, deeply furrowed. Inner bark is whitish (outer surface yellow-orange; inner surface pale yellow), fragrant (upon powdering, a distinctive fenugreek-like odor) and very mucilaginous upon chewing or moistening.

Leaves: Alternate; simple; petiolate with petiole (3–)5–7(–9) mm long; 7–18(–23) cm long, 5–10(–15) cm broad; elliptical to ovate, oblong, or obovate with oblique base and acuminate apex; margins serrate toward base, elsewhere doubly serrate; upper surface scabrous, rough; lower surface tomentose; secondary veins parallel, slightly curved, running to tips of marginal teeth.

Inflorescence: Axillary fascicles, roughly hemispherical, to 1.5(–2.5) cm in diameter.

Flowers: Small, perfect; pedicels 1–2(–3) mm long; calyx campanulate, 5–9-lobed at apex, about 2.6–3.5 mm in diameter, reddish-pubescent; petals absent; stamens 5–9, exserted at flowering; styles 2. Flowers occur before the leaves from March through early May.

Fruit: Winged samara, yellowish, irregularly suborbicular or occasionally broadly elliptical or obovate, 10–20 mm in diameter, reddish-pubescent over seed; wing papery-textured.

Compendial History—Slippery elm (*Ulmus*) inner bark appeared in the list of materia medica in the first *United States Pharmacopoeia (USP)* of 1820 and remained official until it was removed from *USP XI* (1936). The *USP 1820* included instructions for the preparation of *Infusion of Slippery Elm*: “Take of Slippery elm, sliced, one ounce. Boiling water, one pint. Infuse for twelve hours in a covered vessel, near the fire with frequent agitation, and strain.” Immediately following its removal from *USP XI* (official: June 1, 1936), *Slippery Elm Bark* became an official monograph in the sixth edition of the *National Formulary (NF)*, official: June 1, 1936) until its elimination from the 11th edition (official: October 1, 1961). It became official again, as *Elm*, on November 15, 1995, in the *USP* section of the *Third Supplement to the United States Pharmacopoeia–National Formulary (USP 23–NF 18)*. A revision was published in the *Seventh Supplement* on November 15, 1997.

In 1982, Elm Bark appeared in the Food and Drug Administration (FDA) Advance Notice of Proposed Rulemaking (ANPR) for the establishment of a therapeutic monograph for oral health care drug products for over-the-counter (OTC) human use. In the ANPR (1982) as well as in the subsequent tentative final monograph of 1988 and in the amendment to the monograph of 1991, Elm bark was classified as a Category I (Generally Recognized as Safe and Effective (GRASE)) OTC oral demulcent active ingredient, and appropriate standards were urged to be developed in the official compendia.

Aside from *USP–NF*, the monograph of *Elm* had already appeared in the second edition of *The Dispensatory of the United States of America* (1834), and its last appearance was in the 25th edition, 1960.

Constituents—Constituents of relevance for conformance to *Identification A* under *Elm* are mucilaginous substances. Elm inner bark mucilage is readily extractable by water and consists principally of a polysaccharide which on hydrolysis yields D-galactose, D-methyl galactose, L-rhamnose, and glucose. Borohydride reduction of the periodate-oxidized polysaccharide affords, on partial hydrolysis with hot acid, three oligosaccharides: O-(3-O-methyl-β-D-galactopyranosyl)-(1→4)-O-(3-O-methyl-β-D-galactopyranosyl)-(1→4)-L-rhamnose, O-(3-O-methyl-β-D-galactopyranosyl)-(1→4)-L-rhamnose, and O-(3-O-methyl-β-D-galactopyranosyl)-(1→4)-3-O-methyl-D-galactose.

Other Elm constituents are traces of tannins, including proanthocyanidins, some starch, traces of oxalate salts, beta-sitosterol, and minerals.

Sources and Distribution—

Sources—Slippery elm bark is harvested from wild populations in eastern Canada and the United States, from southern Quebec west to North Dakota, south to south-central Texas, and Florida. It is common throughout eastern, southern, and midwestern U.S., and it grows in more than 25 states. An increasing amount of the commercial supply is being collected according to sustainable wild resource man-

agement plans as a condition of organic certification for wild crops. Conversely, Dutch elm disease has had a significant negative impact on elm populations, from 1930 when it was first found in the United States affecting over 50% of elm trees in the northern states.

Distribution—Canada (New Brunswick, Ontario, Quebec), the United States (Alabama, Arkansas, Connecticut, Delaware, the District of Columbia, Florida, Georgia, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, New Hampshire, New Jersey, New York, North Carolina, North Dakota, Ohio, Oklahoma, Pennsylvania, Rhode Island, South Carolina, South Dakota, Tennessee, Texas, Virginia, Vermont, Wisconsin, and West Virginia).

Collection and Cultivation—

Collection (Conservation and Ecology)—“Natural” (both inner and outer bark) and “rossed” (inner bark only) are harvested, but only the rossed bark will conform to the standards of the *USP* monograph. Harvesting should occur on dry, preferably warm days with no chance of precipitation, and it usually commences in late morning after the morning dew and humidity pass. This is because post-harvest processing (rossing) generally takes place at the collection site outdoors and humidity can damage the quality of the inner bark. Because the inner bark contains polysaccharide mucilage, when it comes in contact with moisture, it begins to gel.

The bark, from trees of a minimum age of 10 years (some harvesters recommend selecting at least 12- to 15-year-old trees) is obtained mainly by pruning or trimming the lower limbs and branches, but can also be obtained from the bole (trunk) and, very rarely, even from the roots in cases where the entire tree is felled. While the inner bark of the root reportedly contains more mucilage than that of the trunk or branches, sustainable wild resource management dictates harvesting only the branches of mature trees. In practice, commercial bark collectors are more likely to select branches from trees that are at least 30 to 50 years old in order to obtain a high enough yield. After pruning, the tree will heal over where harvested and continue to grow, but the trunk and/or branches should never be girdled, because this will kill the tree. Girdling is the stripping away of bark from the trunk or a branch all the way around. In practice, the most sustainable method of harvest from mature healthy trees is to prune off entire lower branches in a way that will not harm the tree. If sawn properly so that rainwater will not drop directly into the exposed cut area, the tree will grow over the cut area within a couple of years. The proper cut, which is made just outside the branch collar and the branch bark ridge, does the least amount of damage to the trees.

Although elm bark should not be gathered from already dead trees, selective collection from dying trees—for example, those affected with Dutch elm disease—is feasible. The fungus that causes Dutch elm disease, *Ophiostoma ulmi* and *Ophiostoma novo-ulmi* (syn: *Graphium ulmi* or *Ceratocystis ulmi*), is carried from tree to tree by the European elm bark beetle (*Scolytus multistriatus*), which arrived in North America on a ship carrying logs from Europe around 1930, and to a much lesser extent by the native elm bark beetle (*Hylurgopinus rufipes*). Elms appear to succumb to the disease at about 10 years of age and then die off in a two-year period. Once a tree is diagnosed with Dutch elm disease, healthy bark can still be harvested for about two years, up until the tree is near death. To monitor how long harvesting can continue, one can use a drawknife to take samples. Once the inner bark is showing increasingly noticeable black streaking, and as more and more limbs die and debarking is evident, the tree is near death. The near-dead tree can be dropped, and the remaining healthy bark can be stripped from the entire tree. Discolored (black-streaked) inner bark should be separated out and discarded. Pruning lower limbs from healthy trees and/or selectively harvesting entire older trees that are near death can both be acceptable methods

as part of a sustainable resource management plan for a specific area of forest under organic supervision.

Following organic production system rules (e.g., for harvest site selection, absence of prohibited substances, testing of soil and water, disallowed inputs, periodic residue testing, documentation control, independent inspection) will more likely result in botanical raw material that meets the general requirements for pesticide residue and heavy metals limits, among other potential contaminants. Certified organic production of wild elm bark requires producers to promote ecological balance and conserve biodiversity. Wild collected elm bark that is to be certified organic must be harvested from a designated area that has had no prohibited substance applied to it for a period of 3 years immediately preceding the harvest, and must be harvested in a manner that ensures that such harvesting or gathering will not be destructive to the environment and will sustain the growth and production of the wild crop. Wild crop producers must comply with the same organic system plan requirements and conditions, as applicable to their operation, as their counterparts who produce cultivated crops. The producer of organic wild harvested elm bark must initiate practices to support biodiversity and avoid, to the extent practicable, any activities that would diminish it. Production practices must maintain or improve the natural resources of the operation, including soil, water, wetlands, woodlands, and wildlife. This is accomplished, in part, by developing and executing a resource management plan that requires wild harvest from stable populations, minimizing disruption of priority species/sensitive habitats, avoiding erosion, allowing reestablishment, and monitoring wild crop sustainability.

Cultivation Practices—Even though the commercial supply is harvested from wild populations, slippery elm trees can be propagated by cuttings or by seed. For propagation by seed, the ripe seeds are collected from April to June from healthy and successful (dominant) trees from an area similar to the proposed planting site. A ripeness indicator is when the samaras (fruits) are green. It is best to collect seed from trees within 160 km north or south of the planting site, as potential for success is optimal within this range from the parents. Twenty-five seeds per square foot can be scattered, 0.6 cm deep. Slippery elm may be sown as in its normal cycle in the spring in a raised peat moss soil and sand bed. The seedbeds may need a wire top to protect young seedlings. Germination rate is 10% to 25%, with light germination in summer and increased germination the following spring. The young trees can be transplanted into tree tubes within the first month of germination and field planted after one or two years, depending on the size of the tree tube. The tree saplings must be watered during times of drought and routinely checked for insect predation and indications of fertilization needs.

Optimal Times for Harvest—Harvest should preferably occur in the spring (March to May), but can also take place in the autumn. In the spring, bark is harvested from mature trees (minimum 10 years) when the sap begins to rise.

Post-Harvest Handling—

Optimal Handling and Processing Practices—To produce pharmacopeial quality elm inner bark, the outer corky layer of bark must be removed, exposing the inner bark. If post-harvest processing occurs at the wild collection site, the pruned limbs and branches should be placed onto clean tarps and not directly on the ground. The very small branches with leaves are stripped off the pruned limbs by hand and discarded. To optimize conformance to standards for composition, identity, purity, and quality (e.g., NMT 2% of adhering outer bark, NMT 2% foreign organic matter, NMT 10% total ash, and NMT 0.65% acid-insoluble ash), a clean bark rosser (hand tool with handle and knife blade)

should be used to shave off the outer bark. The rough, scaly matter on the surface of the bark is called *ross*, and to *ross* bark is to scrape or shave the outer bark from the limb. An experienced rosser can visually discern that at least 98% of the outer bark has been shaved off. The inner bark is white in color (in the spring; reddish later in the season) in obvious visible contrast to the brown outer bark layer. After most of the outer bark is rossed off, greater care must be exercised to very carefully slice off the remaining thin layer of outer bark so as not to waste any of the inner bark in the process. After removal of the outer bark, the inner bark can then be removed in strips, squares, or chips. An incision is made with a clean knife down the center of the limb. Then a clean crowbar is slipped underneath the incision in order to lift and peel the inner bark off from the cambium. The strips of inner bark are stacked on a clean tarp and later bundled for transport to the drying facility.

Drying—*Elm USP* requires a loss on drying limit of NMT 12%. So long as rain is not expected, fresh elm inner bark can be sun-cured within a temperature range of 32° to 60°. Drying can also be carried out in a warm room with airflow or in a greenhouse. Greenhouse drying takes about 3 to 4 days. Drying indoors can take 5 to 7 days, depending on the heat source. Drying at commercial scale, however, is done typically in enclosed drying chambers, in which time and temperature can be better controlled. The strips of elm bark are placed onto a clean screen floor and dried over about 2 days' time at about 50° with fan-forced heat through the floor. Because of additional phytosanitary requirements for export of tree barks to Europe, higher heat exposure is necessary, usually at least 65° but up to 93° for up to two days. Post-drying, the strips of inner bark can be cut or sawn into pieces of equal length and bound into bundles with wire. The bundles usually consist of flat, oblong pieces, about 30 cm in length and from 10 to 15 cm in width. The bark strips can be stored this way until further processing (e.g., cutting or powdering) is scheduled.

Storage—To maintain pharmacopeial purity and quality (e.g., to prevent accumulation of excess moisture), dried elm inner bark should be preserved in well-closed containers, and stored in a cool, dry place.

Adulterants and Contaminants—Common contaminants that could cause a material not to conform with the identification tests in the *Elm* monograph in *USP* would include other plant parts: for example, greater than 2% outer bark, which lacks mucilage. Insufficient shaving or rossing of outer bark could cause the material to exceed the monograph limit of NMT 2% of adhering outer bark. Other possible contaminants would include visible discolored inner bark, although no maximum limit has been established (for example, inner bark with visible black streaking obtained from a diseased tree). Powdered bark can also be adulterated with cornmeal, rice flour, starch, or other starchy substances. Consequences of contamination with outer bark or adulteration with flour or starch are lower mucilage content, lower swelling index value, and correspondingly less of a therapeutic demulcent effect that is mucilage-dependent. Excess outer bark could also cause the material to fail the quantitative standard of NMT 10% total ash. Methods to determine the presence of adulterants include microscopic examination in order to determine the presence of excess outer bark or any other adulterant and the concentration of mucilage cells. The *Elm* mucilage test (*Identification A*) as well as a modified swelling volume test (based on the test in the *USP* monograph *Psyllium Husk*) may also be useful to investigate if adulteration is suspected.

(2040) DISINTEGRATION AND DISSOLUTION OF DIETARY SUPPLEMENTS

Change to read:

INTRODUCTION

This general chapter is provided to determine compliance with the disintegration and dissolution standards for dietary supplements where stated in the individual monographs.

For the purposes of this chapter, dietary supplement dosage forms have been divided into three categories: *Vitamin–Mineral Dosage Forms*, *Botanical Dosage Forms*, and *Dietary Supplements Other Than Vitamin–Mineral and Botanical Dosage Forms*. *Vitamin–Mineral Dosage Forms* includes articles prepared with vitamins, minerals, or combinations of these dietary ingredients, ▲ as described in Table 1.▲ ^{USP36} *Botanical Dosage Forms* comprises formulations containing ingredients of botanical origin, including plant materials and extracts. *Dietary Supplements Other Than Vitamin–Mineral and Botanical Dosage Forms* encompasses dietary supplements formulated with lawfully recognized dietary ingredients that are different from those pertaining to the two foregoing categories (e.g., amino acids, chondroitin, and glucosamine.)

Where a dietary supplement represents a combination of the categories mentioned above, and there is a difference between the requirements for the individual categories, the more stringent requirement applies. ▲ [NOTE—“More stringent requirement” means stricter acceptance criteria and/or milder operational conditions.]

Disintegration and dissolution tests as described in this chapter are quality-control tools to assess performance characteristics of dietary supplement finished dosage forms. These performance standards are intended to detect problems that may arise due to use or misuse, or changes in coatings, lubricants, disintegrants, and other components. These performance tests are also intended to detect manufacturing process issues such as over-compression and over-drying that would affect the release characteristics of the final dosage forms. These tests are not intended to be used as a demonstration or as a surrogate for in vivo absorption, bioavailability, or effectiveness, unless an in vitro–in vivo correlation (IVIVC) has been established.▲ ^{USP36}

Change to read:

DISINTEGRATION

This test is provided to determine whether dietary supplement tablets or capsules disintegrate within the prescribed time when placed in a liquid medium at the experimental conditions presented below. Compliance with the limits on *Disintegration* stated in the individual monographs for dietary supplements is required except where the label states that the products are intended for use as troches, are to be chewed, or are designed as extended-release dosage forms. Dietary supplements claiming to be extended-release dosage forms must comply with standards other than disintegration to verify that the release of the dietary ingredients from the dosage form is for a defined period of time. Dietary supplements claiming to be extended-release dosage forms shall

not be labeled as in compliance with USP unless a USP monograph exists for such product. Determine the type of units under test from the labeling and from observation, and apply the appropriate procedure to 6 or more units.

For purposes of this test, disintegration does not imply complete solution of the unit or even of its active constituent. Complete disintegration is defined as that state in which any residue of the unit, except fragments of insoluble coating or capsule shell, remaining on the screen of the test apparatus or adhering to the lower surface of the disk, if used, is a soft mass having no palpably firm core.

Apparatus

Apparatus A: Use the *Apparatus* described under *Disintegration* (701) for tablets or capsules that are not greater than 18 mm long. For larger tablets or capsules, use *Apparatus B*.

Apparatus B: The apparatus¹ consists of a basket-rack assembly, a 1000-mL low-form beaker for the immersion fluid, a thermostatic arrangement for heating the fluid between 35° and 39°, and a device for raising and lowering the basket in the immersion fluid at a constant frequency rate between 29 and 32 cycles per min through a distance of NLT 53 mm and NMT 57 mm. The volume of the fluid in the vessel is such that at the highest point of the upward stroke the wire mesh remains at least 15 mm below the surface of the fluid and descends to NLT 25 mm from the bottom of the vessel on the downward stroke. At no time should the top of the basket-rack assembly become submerged. The time required for the upward stroke is equal to the time required for the downward stroke, and the change in stroke direction is a smooth transition rather than an abrupt reversal of motion. The basket-rack assembly moves vertically along its axis. There is no appreciable horizontal motion or movement of the axis from the vertical.

Basket-Rack Assembly: The basket-rack assembly (see Figure 1) consists of three open-ended transparent tubes, each 77.5 ± 2.5 mm long and having an inside diameter of 32.0–34.6 mm and a wall 2.0–3.0 mm thick; the tubes are held in a vertical position by two plastic plates, each 97 ± 2 mm in diameter and 7.5–10.5 mm in thickness, with three holes, 36.0–40.6 mm in diameter, equidistant from the center of the plate and equally spaced from one another. Attached to the undersurface of the lower plate is 10-mesh No. 23 (0.025-inch) W. and M. gauge woven stainless-steel wire cloth having a plain square weave. The parts of the apparatus are assembled and rigidly held by means of three bolts passing through the two plastic plates. A suitable means is provided to suspend the basket-rack assembly from the raising and lowering device, using a point on its axis.

The design of the basket-rack assembly may be varied somewhat, provided that the specifications for the glass tubes and the screen mesh size are maintained.

Beaker: Low form, 1000 mL; the difference between the diameter of the plastic plates, which hold the tubes in a vertical position, and the inside diameter of the beaker should be NMT 6 mm.²

Disks: Each tube is provided with a perforated cylindrical disk 15.3 ± 0.15 mm thick and 31.4 ± 0.13 mm in diameter. The disk is made of a suitable, transparent plastic material having a specific gravity of between 1.18 and 1.20. Seven 3.15 ± 0.1-mm ▲ in diameter,▲ ^{USP36} holes extend between the ends of the cylinder, ▲ one of the holes being in the center and the other six parallel with it and spaced

¹ An apparatus and disks meeting these specifications are available from Varian Inc., 13000 Weston Parkway, Cary, NC 27513, or from laboratory supply houses.

² 1000-mL low-form beakers, designed in compliance with the current ASTM E 960 Type I or Type II or ISO 3819 specifications, meet the size requirements.

Figure 1. Basket-rack assembly, *Disintegration, Apparatus B* (dimensions in mm).

equally tangent to a circle with a radius of 4.2-mm from the center of the disc.▲▲³ USP36 All surfaces of the disk are smooth.³

Procedure

▲ Test 6 dosage forms as described below for each dosage type. [NOTE—Two basket arrangements for a total of 6 tubes are necessary for *Apparatus B*.] If 1 or 2 dosage forms fail to disintegrate completely, repeat the test on 12 additional dosage forms.▲▲³ USP36

Uncoated Tablets: Place 1 tablet in each of the tubes of the basket and, if prescribed, add a disk to each tube. Operate the apparatus, using water or the specified medium as the immersion fluid, maintained at $37 \pm 2^\circ$. At the end of 30 min, lift the basket from the fluid, and observe the tablets. ▲▲³ USP36

³ The use of automatic detection using modified disks is permitted where the use of disks is specified or allowed. Such disks must comply with the requirements for density and dimensions given in this chapter.

Plain Coated Tablets: Place 1 tablet in each of the tubes of the basket and, if the tablet has a soluble external sugar coating, immerse the basket in water at room temperature for 5 min. Then, if prescribed, add a disk to each tube, and operate the apparatus, using water or the specified medium as the immersion fluid, maintained at $37 \pm 2^\circ$. At the end of 30 min, lift the basket from the fluid, and observe the tablets. ▲▲³ USP36

Delayed-Release (Enteric-Coated) Tablets: ▲ Omit the use of a disk.▲▲³ USP36 Place 1 tablet in each of the 6 tubes of the basket, and if the tablet has a soluble external sugar coating, immerse the basket in water at room temperature for 5 min. Then operate the apparatus using simulated gastric fluid TS maintained at $37 \pm 2^\circ$ as the immersion fluid. After 1 h of operation in simulated gastric fluid TS, lift the basket from the fluid, and observe the tablets: the tablets show no evidence of disintegration, cracking, or softening. Operate the apparatus, using simulated intestinal fluid TS, maintained at $37 \pm 2^\circ$, as the immersion fluid for the time specified in the monograph. Lift the basket from the fluid, and observe the tablets. ▲▲³ USP36

Delayed-Release (Enteric-Coated) Soft Shell Capsules:

Place 1 softgel capsule in each of the 6 tubes of the basket. ▲▲ *USP36* Omit the use of a disk. Operate the apparatus using simulated gastric fluid TS maintained at $37 \pm 2^\circ$ as the immersion fluid. After 1 h of operation in simulated gastric fluid TS, lift the basket from the fluid and observe the softgels: the softgels show no evidence of disintegration or rupture permitting the escape of the contents. Operate the apparatus with disks, using simulated intestinal fluid TS, maintained at $37 \pm 2^\circ$, as the immersion fluid ▲ for NMT 60 min. ▲ *USP36* Lift the basket from the fluid, and observe the capsules. ▲▲ *USP36*

Buccal Tablets: Apply the test for *Uncoated Tablets*. After 4 h, lift the basket from the fluid, and observe the tablets. ▲▲ *USP36*

Sublingual Tablets: Apply the test for *Uncoated Tablets*. At the end of the time limit specified in the individual monograph, ▲ observe the tablets. ▲ *USP36*

Hard Shell Capsules: Apply the test for *Uncoated Tablets*, using as the immersion fluid, maintained at $37 \pm 2^\circ$, a 0.05 M acetate buffer prepared by mixing 2.99 g of sodium acetate trihydrate and 1.66 mL of glacial acetic acid with water to obtain a 1000-mL solution having a pH of 4.50 ± 0.05 . Attach a removable wire cloth, as described in *Basket-Rack Assembly*, to the surface of the upper plate of the basket-rack assembly. At the end of 30 min, lift the basket from the fluid, and observe the capsules. ▲▲ *USP36*

Soft Shell Capsules: Proceed as directed in *Rupture Test for Soft Shell Capsules*.

Use of Disks

Vitamin–Mineral Dosage Forms: Add a disk to each tube unless otherwise specified ▲ in the *Procedure* above or ▲ *USP36* in the individual monograph.

Botanical Dosage Forms: Omit the use of disks unless otherwise specified ▲ in the *Procedure* above or ▲ *USP36* in the individual monograph.

Dietary Supplements Other Than Vitamin–Mineral and Botanical Dosage Forms: Omit the use of disks unless otherwise specified ▲ above or ▲ *USP36* in the individual monograph.

▲ Tolerances

All of the 6 dosage forms initially tested or NLT 16 of a total of 18 dosage forms tested disintegrate completely. ▲ *USP36*

RUPTURE TEST FOR SOFT SHELL CAPSULES

Medium: Water; 500 mL.

Apparatus: Use *Apparatus 2* as described in *Dissolution* (711), operating at 50 rpm.

Time: 15 min

Procedure: Place 1 capsule in each vessel, and allow the capsule to sink to the bottom of the vessel before starting rotation of the blade. Use sinkers if the capsules float. Observe the capsules, and record the time taken for each capsule shell to rupture.

Tolerances: The requirements are met if all of the capsules tested rupture in NMT 15 min. If 1 or 2 of the capsules rupture in more than 15 but NMT 30 min, repeat the test on 12 additional capsules: NMT 2 of the total of 18 capsules tested rupture in more than 15 but NMT 30 min. For soft gelatin capsules that do not conform to the above rupture test acceptance criteria, repeat the test with the addition of purified pepsin to the *Medium* that results in an activity of 750,000 Units or less per 1000 mL.

Change to read:**DISSOLUTION**

This test is provided to determine compliance with the *Dissolution* requirements where stated in the individual monograph for dietary supplements, except where the label states that tablets are to be chewed. ▲ The operative assumption inherent in this test is that if the index vitamin or mineral or marker compound(s) for a botanical is dissolved within the time frame and under conditions specified, the dosage form does not suffer from formulation or manufacturing-related problems affecting the adequate release of the active ingredients.

Apparatus▲ *USP36*

See *Dissolution* (711) for description of apparatus used, *Apparatus Suitability Test*, and other related information.

▲▲ *USP36* Figure 2 shows the schematic view of a flow-through cell ▲ (USP Apparatus 4) specifically intended for dissolution of lipid-filled soft shell capsules. ▲ *USP36* The lower part (1) is made up of two adjacent chambers connected to an overflow device. The dissolution medium passes through chamber A and is subjected to an upward flow. The flow in chamber B is directed downward to a small-size bore exit that leads upward to a filter assembly. The middle part (2) of the cell has a cavity designed to collect lipophilic excipients that float on the dissolution medium. A metal grid serves as a rough filter. The upper part (3) holds a filter unit for paper, glass fiber, or cellulose filters.

Figure 2. Flow-through cell designed for lipid-filled soft gelatin capsules (dimensions in mm).

Of the types of apparatus described in (711), use the one specified in the individual monograph.

For hard or soft gelatin capsules and gelatin-coated tablets that do not conform to the dissolution specification, repeat the test as follows. Where water or a medium with a pH of less than 6.8 is specified as the *Medium* in the individ-

ual monograph, the same *Medium* specified may be used with the addition of purified pepsin that results in an activity of 750,000 Units or less per 1000 mL. For media with a pH of 6.8 or greater, pancreatin can be added to produce NMT 1750 USP Units of protease activity per 1000 mL.

▲▲ USP36

Vitamin–Mineral Dosage Forms

▲ All dietary supplement tablets or capsules containing folic acid are subject to the dissolution test and criteria described in this chapter for folic acid. This test is required because of the importance of the relationship between folate deficiency and the risk of neural tube defects. Dietary supplements tablets or capsules containing water-soluble vitamins, minerals, or their combination are subject to the dissolution test and criteria described in this chapter for index vitamins, index minerals, or both. Dietary supplement tablet and hard shell capsule with solid contents dosage forms containing vitamin A are subject to the dissolution test and criteria described in this chapter for vitamin A. Dissolution standards were not established and therefore not applicable to vitamin A in dietary supplement soft shell capsules filled with liquids. *Table 1* summarizes the dissolution requirements for the assigned USP classes of dietary supplements. Vitamin–mineral combinations that don’t belong to any of the USP classes listed in the *Table 1* are subject to the dissolution test and criteria specified in the individual monographs.

Table 1. Dietary Supplements—Vitamin–Mineral Dosage Forms

USP Class	Ingredients	Dissolution Requirement for Tablets and Hard Shell Capsules With Solid Contents	Dissolution Requirement for Soft Shell Capsules Filled With Liquids
I	Oil-Soluble Vitamins	vitamin A (if present)	not applicable
II	Water-Soluble Vitamins	one index water-soluble vitamin and folic acid (if present)	one index water-soluble vitamin and folic acid (if present)
III	Water-Soluble Vitamins with Minerals	one index water-soluble vitamin, one index element, and folic acid (if present)	one index water-soluble vitamin, one index element, and folic acid (if present)
IV	Oil- and Water-Soluble Vitamins	vitamin A (if present), one index water-soluble vitamin, and folic acid (if present)	one index water-soluble vitamin and folic acid (if present)
V	Oil- and Water-Soluble Vitamins with Minerals	vitamin A (if present), one index water-soluble vitamin, one index element, and folic acid (if present)	one index water-soluble vitamin, one index element, and folic acid (if present)

Table 1. Dietary Supplements—Vitamin–Mineral Dosage Forms (Continued)

USP Class	Ingredients	Dissolution Requirement for Tablets and Hard Shell Capsules With Solid Contents	Dissolution Requirement for Soft Shell Capsules Filled With Liquids
VI	Minerals	one index element	one index element
VII	Oil-Soluble Vitamins with Minerals	vitamin A (if present) and one index element	one index element

▲ USP36

SELECTION OF INDEX ▲ WATER-SOLUBLE▲ USP36 VITAMINS AND INDEX ELEMENTS

Compliance with the dissolution requirements for dietary supplements representing combinations of water-soluble vitamins (*Water-Soluble Vitamins Capsules* and *Water-Soluble Vitamins Tablets*) and combinations of oil- and water-soluble vitamins (*Oil- and Water-Soluble Vitamins Capsules* and *Oil- and Water-Soluble Vitamins Tablets*) is determined by measuring the dissolution of a single index vitamin from the water-soluble vitamins present. Riboflavin is the index vitamin when present in the formulation. For formulations that do not contain riboflavin, pyridoxine is the index vitamin. If neither riboflavin nor pyridoxine is present in the formulation, the index vitamin is niacinamide (or niacin), and in the absence of niacinamide (or niacin), the index vitamin is thiamine. If none of the above four water-soluble vitamins is present in the formulation, the index vitamin is ascorbic acid.

Compliance with the dissolution requirements for dietary supplements representing combinations of minerals (*Minerals Capsules* and *Minerals Tablets*) is determined by measuring the dissolution of only one index element. Iron is the index element when present in the formulation. For formulations that do not contain iron, the index element is calcium. If neither iron nor calcium is present, the index element is zinc, and in the absence of all three of these elements, magnesium is the index element.

Compliance with the dissolution requirements for dietary supplements representing combinations of water-soluble vitamins and minerals (*Water-Soluble Vitamins with Minerals Capsules* and *Water-Soluble Vitamins with Minerals Tablets*) and combinations of oil- and water-soluble vitamins and minerals (*Oil- and Water-Soluble Vitamins with Minerals Capsules* and *Oil- and Water-Soluble Vitamins with Minerals Tablets*) is determined by measuring the dissolution of one index water-soluble vitamin and one index element, designated according to the respective hierarchies described above.

DISSOLUTION CONDITIONS FOR VITAMIN A TABLETS

NOTE—Perform this test under light conditions that minimize photodegradation.

Medium: 1% (w/v) sodium ascorbate and 1% (w/v) octoxynol 9 in 0.05 M phosphate buffer pH 6.8; 900 mL

Apparatus 2: 75 rpm

Time: 45 min

DISSOLUTION CONDITIONS FOR FOLIC ACID

NOTE—Perform this test under light conditions that minimize photodegradation.

Test 1

Medium: Water; 900 mL. If the units tested do not meet the requirements for dissolution in water, test 6 additional dosage units for dissolution in a medium of 900 mL of 0.05 M pH 6.0 citrate buffer solution, prepared by mixing 9.5 mL of 0.1 M citric acid monohydrate and 40.5 mL of 0.1 M sodium citrate dihydrate in a 100-mL volumetric flask, diluting with water to volume, mixing, and adjusting to a pH of 6.0 by using either 0.1 M hydrochloric acid or 0.1 M sodium hydroxide solution.

Apparatus 1: 100 rpm, for capsules

Apparatus 2: 75 rpm, for tablets

Time: 1 h

Test 2: If the product complies with this test, the labeling indicates that it meets USP *Dissolution Test 2*.

Medium: 45 mM citrate buffer, pH 6.0; 250 mL

Apparatus 3: 30 dpm

Screen (Top & Bottom): 56-mesh

Time: 1 h

NOTE—Compliance with the dissolution requirements for folic acid does not exempt the product from dissolution testing of the pertinent index vitamin or the corresponding index mineral.

DISSOLUTION CONDITIONS FOR INDEX WATER-SOLUBLE VITAMINS AND INDEX MINERALS

Test 1

Medium: 0.1 N hydrochloric acid; 900 mL

Apparatus 1: 100 rpm, for capsules

Apparatus 2: 75 rpm, for tablets

Time: 1 h

For formulations containing 25 mg or more of the index vitamin, riboflavin, use the following conditions:

Medium: 0.1 N hydrochloric acid; 1800 mL

Apparatus 1: 100 rpm, for capsules

Apparatus 2: 75 rpm, for tablets

Time: 1 h

Test 2 (Not suitable for Minerals)

If the product complies with this test, the labeling indicates that it meets USP *Dissolution Test 2*.

Medium: 45 mM citrate buffer, pH 6.0; 250 mL

Apparatus 3: 30 dpm

Screen (Top & Bottom): 56-mesh

Time: 1 h

NOTE—Compliance with dissolution requirements for the pertinent index vitamin or index mineral does not exempt the product from dissolution testing of folic acid, if present.

PROCEDURES

In the following procedures, combine equal volumes of the filtered solutions of the 6 individual specimens withdrawn, and determine the amount of vitamin A, folic acid, or the index vitamin or element dissolved, based on the average of 6 units tested. Make any necessary modifications including concentration of the analyte in the volume of *Sample solution* taken. Use the *Medium* for preparation of the *Standard solution* and dilution, if necessary, of the *Sample solution*.

Vitamin A: Determine the percentage of retinyl acetate or retinyl palmitate dissolved by using the following procedure.

Sample solution: Withdraw a portion of the solution under test, pass through a suitable filter of 0.45- μ m pore size, and use the pooled sample as the test specimen.

Standard solution: Dissolve a suitable amount of USP Retinyl Acetate RS or USP Retinyl Palmitate RS in isopropyl

alcohol, and dilute with *Medium* to obtain a concentration similar to that expected in the *Sample solution*. [NOTE—The amount of alcohol should be 5%–10%.]

Solution A: Methanol and water (90:10)

Solution B: Methanol and isopropyl alcohol (55:45)

Mobile phase: See *Table 2*.

Table 2

Time (min)	Solution A (%)	Solution B (%)
0	100	0
8	0	100
13	0	100
13.1	100	0
15	100	0

Chromatographic system

(See *Chromatography* (621), *System Suitability*.)

Mode: LC

Detector: UV 325 nm

Column: 4.6-mm \times 10-cm; 3- μ m packing L1

Flow rate: 1.0 mL/min

Injection volume: 50 μ L

System suitability

Sample: *Standard solution*

Suitability requirements

Tailing factor: NMT 1.5 for retinyl acetate and NMT 2.0 for retinyl palmitate

Relative standard deviation: NMT 2.0%

Analysis

Samples: Appropriate *Standard solution* and *Sample solution*

$$\text{Result} = (r_U/r_S) \times (C_S \times V/L) \times 100$$

r_U = peak area of the all-*trans*-retinyl ester from the *Sample solution*

r_S = peak area of the all-*trans*-retinyl ester from the appropriate *Standard solution*

C_S = concentration of retinol ($C_{20}H_{30}O$) in the appropriate *Standard solution* (μ g/mL)

V = volume of *Medium*, 900 mL

L = label claim of vitamin A, as retinol ($C_{20}H_{30}O$) (μ g/Tablet)

Folic Acid: Determine the amount of $C_{19}H_{19}N_7O_6$ dissolved by using the procedure set forth in the assay for *Folic Acid in Oil- and Water-Soluble Vitamins with Minerals Tablets*, in comparison with a *Standard solution* having a known concentration of USP Folic Acid RS in the same *Medium*.

Niacin or Niacinamide, Pyridoxine, Riboflavin, and Thiamine: Determine the amount of the designated index vitamin dissolved by using the procedure set forth in the *Assay for Niacin or Niacinamide, Pyridoxine Hydrochloride, Riboflavin, and Thiamine in Water-Soluble Vitamins Tablets*.

Ascorbic Acid: Determine the amount of $C_6H_8O_6$ dissolved by adding 10 mL of 1.0 N sulfuric acid and 3 mL of starch TS to 100.0 mL of *Sample solution*, and titrating immediately with 0.01 N iodine VS. Perform a blank determination, and make any necessary correction.

Iron, Calcium, Magnesium, and Zinc: Determine the amount of the designated index element dissolved by using the procedure set forth in the appropriate assay in *Minerals Capsules*.

TOLERANCES

The requirements are met if NLT 75% of the labeled content of vitamin A, NLT 75% of the labeled content of folic

acid, and NLT 75% of the labeled content of the index vitamin or the index element from the units tested is dissolved.

Botanical Dosage Forms

Compliance with dissolution requirements necessitates the testing of 6 dosage units individually, or testing 2 or more dosage units in each of the 6 vessels of the dissolution apparatus, and measuring the dissolution of one or more index/marker compound(s) or the extract specified in the individual monograph.

PROCEDURES

Combine equal volumes of the filtered solutions of the 6 or more individual specimens withdrawn, and use the pooled sample as the *Sample solution*. Determine the average amount of index or marker compound(s) or the extract dissolved in the pooled sample by the procedure specified in the individual monograph. Make any necessary modifications, including concentration of the analyte in the volume of the *Sample solution* taken. Use the *Medium* for preparation of the *Standard solution* and dilution, if necessary, of the *Sample solution*.

TOLERANCES

Unless otherwise specified in the individual monograph, the requirements are met if NLT 75% of the labeled content of the index or marker compound(s) or the extract from the units tested is dissolved in 1 h.

Dietary Supplements Other Than Vitamin–Mineral and Botanical Dosage Forms

Unless otherwise stated in the individual monographs for dietary supplement dosage forms in this category, compliance requires the testing of 6 individual units, measuring the dissolution of the dietary ingredient as the average of the 6 units tested.

PROCEDURES

Combine equal volumes of the filtered solutions of the 6 specimens withdrawn, and use the pooled sample as the *Sample solution*. Determine the average amount of dietary ingredient dissolved in the pooled sample by the procedure specified in the individual monograph. Make any necessary modifications, including concentration of the analyte in the volume of the *Sample solution* taken. Use the *Medium* for preparation of the *Standard solution* and for dilution, if necessary, of the *Sample solution*.

TOLERANCES

Because of the diversity of chemical characteristics and solubilities of dietary ingredients pertaining to this category,

general tolerances cannot be established. See individual monographs for *Tolerances*.

(2091) WEIGHT VARIATION OF DIETARY SUPPLEMENTS

The following tests provide limits for the permissible variations in the weights of individual tablets or capsules, expressed in terms of the allowable deviation from the average weight of a sample. Separate procedures and limits are described herein for capsules, uncoated tablets, and coated tablets that are intended for use as dietary supplements.

CAPSULES

Capsules meet the requirements of the following test with respect to variation in weight of contents.

Hard Capsules

Weigh 20 intact capsules individually, and determine the average weight. The requirements are met if each of the individual weights is within the limits of 90% and 110% of the average weight.

If not all of the capsules fall within the aforementioned limits, weigh the 20 capsules individually, taking care to preserve the identity of each capsule, and remove the contents of each capsule with the aid of a small brush or pledget of cotton. Weigh the emptied shells individually, and calculate for each capsule the net weight of its contents by subtracting the weight of the shell from the respective gross weight. Determine the average net content from the sum of the individual net weights. Then determine the difference between each individual net content and the average net content: the requirements are met if (a) not more than 2 of the differences are greater than 10% of the average net content and (b) in no case is the difference greater than 25%.

If more than 2 but not more than 6 capsules deviate from the average between 10% and 25%, determine the net contents of an additional 40 capsules, and determine the average content of the entire 60 capsules. Determine the 60 deviations from the new average: the requirements are met if (a) in not more than 6 of the 60 capsules does the difference exceed 10% of the average net content and (b) in no case does the difference exceed 25%.

Soft Capsules

Proceed as directed under *Hard Capsules*, but determine the net weight of the contents of individual capsules as follows. Weigh the intact capsules individually to obtain their gross weights, taking care to preserve the identity of each capsule. Then cut open the capsules by means of a suitable clean, dry cutting instrument, such as scissors or a sharp open blade, and remove the contents by washing with a suitable solvent. Allow the occluded solvent to evaporate from the shells at room temperature over a period of about 30 minutes, taking precautions to avoid uptake or loss of moisture. Weigh the individual shells, and calculate the net contents. The requirements are as stated under *Hard Capsules*.

TABLETS

Tablets conform to the criteria given in the accompanying table.

Uncoated Tablets and Film-Coated Tablets

Weigh individually 20 whole tablets, and calculate the average weight. The requirements are met if the weights of not more than 2 of the tablets differ from the average weight by more than the percentage listed in the accompanying table and no tablet differs in weight by more than double that percentage.

Coated Tablets (Other Than Film-Coated Tablets)

Weigh individually 20 whole tablets, and calculate the average weight. If the coated tablets do not conform to the criteria in the accompanying table, place 20 tablets in a beaker of water at 37°, and swirl gently for not more than 5 minutes. Examine the cores for evidence of disintegration and repeat the procedure for a shorter time if disintegration has begun. Dry the cores at 50° for 30 minutes. Accurately weigh 20 individual tablet cores, and calculate the average weight.

The requirements are met if the weights of not more than 2 of the tablets differ from the average weight by more than the percentage listed in the accompanying table and no tablet differs in weight by more than double that percentage.

Criteria

Weight Variation Tolerances for Uncoated Tablets, Film-Coated Tablets, and Coated Tablets (Other Than Film-Coated Tablets)

Average Weight of Tablet, mg	Percentage Difference
130 or less	10
From 130 through 324	7.5
More than 324	5

(2750) MANUFACTURING PRACTICES FOR DIETARY SUPPLEMENTS

GENERAL PROVISIONS

The principles included in this chapter contain recommended minimum current good manufacturing practices for the methods to be used in, and the facilities and controls to be used for, the manufacture, holding, packaging, labeling, and distribution of dietary ingredients and dietary supplements. These principles are set forth to ensure that such products meet the requirements of safety, have the identity and strength, and meet the quality and purity characteristics that they are represented to possess.

Excluded from this chapter are establishments engaged solely in the harvesting, storage, or distribution of one or

more “raw agricultural commodities” as defined in Section 201(r) of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321(r)), which are ordinarily cleaned, prepared, treated, or otherwise processed before being marketed to the consuming public.

The requirements pertaining to holding dietary ingredients and dietary supplements do not apply to holding those dietary supplements at a retail establishment for the sole purpose of direct retail sale to individual consumers. A retail establishment does not include a warehouse or other storage facility for a retailer or a warehouse or other storage facility that sells directly to individual consumers.

A glossary of terms used in this chapter is presented at the end.

ORGANIZATION AND PERSONNEL

Responsibilities of a Quality Control Unit

A quality control unit shall be established that has the responsibility and authority to approve or reject all raw materials, product containers, closures, in-process materials, packaging material, labeling, and finished dietary supplements, and the authority to review production records to ensure that no errors have occurred or, if errors have occurred, that they have been fully investigated. The quality control unit should be responsible for approving or rejecting products manufactured, processed, packed, or held under contract by another company.

Adequate laboratory facilities for the testing and approval (or rejection) of raw materials, product containers, closures, packaging materials, in-process materials, dietary ingredients, and dietary supplements should be available to the quality control unit.

The quality control unit should have the responsibility for approving or rejecting all procedures or specifications that impact on the identity, strength, quality, and purity of the dietary supplement. All responsibilities and procedures applicable to the quality control unit shall be in writing.

The designated person within the Quality Control Unit who conducts a material review and makes the disposition decision must, at the time of performance, document that material review and disposition decision.

Personnel Qualifications

Each person engaged in the manufacture of dietary ingredients and dietary supplements should have the proper education, training, and experience (or any combination thereof) needed to perform the assigned functions. Training should be in the particular operation(s) that the employee performs as they relate to the employee’s functions.

Appropriate documentation of training shall be retained by the company.

Each person responsible for supervising the manufacture of a dietary ingredient, a dietary supplement, or both should have the proper education, training, and experience (or any combination thereof) to perform assigned functions in such a manner as to provide assurance that the product has the safety, identity, strength, quality, and purity that it is represented to possess.

An adequate number of qualified personnel to perform and supervise the manufacture of each dietary ingredient, dietary supplement, or both product should be provided.

Personnel Responsibilities

The company management shall take all reasonable measures and precautions to ensure the following:

1. *Disease control.* Any person who, by medical examination or supervisory observation, is shown to have, or

appears to have, an illness, open lesion, including boils, sores, or infected wounds, or any other abnormal source of microbial contamination by which there is a reasonable possibility of an in-process or finished dietary ingredient or dietary supplement becoming adulterated, or processing equipment, utensils, or packaging materials becoming contaminated, shall be excluded from any operations which may be expected to result in such adulteration or contamination until the condition is corrected. Personnel shall be instructed to report such health conditions to their supervisors.

2. **Cleanliness.** All persons working in direct contact with raw materials, in-process or finished dietary ingredients and dietary supplements, processing equipment, utensils, or packaging materials shall conform to hygienic practices while on duty to the extent necessary to protect against adulteration or contamination of such materials. The methods for maintaining cleanliness include, but are not limited to, the following:

- Wearing outer garments suitable to the operation in a manner that protects against the adulteration of raw materials or of in-process or finished dietary ingredients and dietary supplements, or contamination of processing equipment, utensils, or packaging materials;
- Maintaining adequate personal cleanliness;
- Removing cosmetics from parts of the body that may contact raw materials, in-process or finished dietary ingredients and dietary supplements, equipment, utensils, or containers;
- Washing hands thoroughly (and sanitizing if necessary to protect against contamination with undesirable microorganisms) in an adequate hand-washing facility before starting work, after each absence from the work station, and at any other time when the hands may have become soiled or contaminated;
- Removing all unsecured jewelry and other objects that might fall into raw materials, in-process or finished dietary ingredients and dietary supplements, equipment, or containers, and removing hand jewelry that cannot be adequately sanitized during periods in which in-process or finished product is manipulated by hand. If such hand jewelry and cosmetics cannot be removed, they may be covered by material that can be maintained in an intact, clean, and sanitary condition and that effectively protects against the adulteration of dietary ingredients and dietary supplements or contamination of processing equipment, utensils or packaging materials;
- Maintaining gloves, if they are used in raw materials or in in-process or finished product handling, in an intact, clean, and sanitary condition. The gloves should be of a material that adequately protects the product from contamination;
- Wearing, where appropriate, in an effective manner, hair nets, caps, beard covers, or other effective hair restraints;
- Storing clothing or other personal belongings in areas other than where in-process or finished product is exposed or where processing equipment or utensils are washed;
- Confining the following actions to areas other than where in-process or finished product may be stored or exposed, or where processing equipment or utensils are washed: eating food, chewing gum, drinking beverages, or using tobacco; and
- Taking any other necessary precautions to protect against adulteration of raw materials or of in-

process or finished product, or contamination of processing equipment, utensils, or packaging materials with microorganisms or foreign substances, including, but not limited to, perspiration, hair, cosmetics, tobacco, chemicals, and medicines applied to the skin.

GROUND, BUILDING, AND FACILITIES

Grounds

The grounds about a dietary ingredient manufacturing plant and a dietary supplement manufacturing plant under the control of the operator shall be kept in a condition that will protect against the adulteration of dietary ingredients and dietary supplements. The methods for adequate maintenance of grounds include, but are not limited to, the following:

- Properly storing equipment, removing litter and waste, and cutting weeds or grass within the immediate vicinity of the plant building or structures that may constitute an attractant, breeding place, or harborage for pests;
- Maintaining roads, yards, and parking lots so that they do not constitute a source of adulteration in areas where product is exposed;
- Adequately draining areas that may contribute to product adulteration by seepage, foot-borne filth, or providing a breeding place for pests; and
- Operating systems for waste treatment and disposal in an adequate manner so that they do not constitute a source of adulteration in areas where product is exposed. If the plant grounds are bordered by grounds not under the operator's control and not maintained in the manner described above, care shall be exercised in the plant by inspection, extermination, or other means to exclude pests, dirt, and filth that may be a source of product adulteration.

Building Design

Any building or buildings used in the manufacture of a dietary ingredient, a dietary supplement, or both should be of suitable size and shall be constructed in such a manner that floors, walls, and ceilings may be adequately cleaned and kept clean and in good repair; that drips or condensates from fixtures, ducts, and pipes do not adulterate raw materials or in-process or finished dietary ingredients and dietary supplements, or contaminate product containers, utensils, or packaging materials; and that aisles or working spaces are provided between equipment and walls and are adequately unobstructed and of adequate width to permit employees to perform their duties and to protect against adulterating in-process or finished product, or contaminating processing equipment with clothing or personal contact. Adequate screening or other protection against pests and insects should be installed, where necessary. The building should have adequate space for the orderly placement of equipment and materials to prevent mixups between different raw materials, product containers, closures, labeling, in-process materials, or finished products, and to prevent contamination. The flow of raw materials, product containers, closures, labeling, in-process materials, and products through the building or buildings should be designed to prevent contamination.

Operations should be performed within specifically defined areas of adequate size to prevent contamination or mixups or adulteration of in-process or finished dietary ingredients and dietary supplements, or contamination of processing equipment, utensils, or packaging materials with microorganisms, chemicals, filth, or other extraneous materials. The potential for mixups and product adulteration may be

reduced by adequate product safety controls and operating practices or effective design, including the separation of operations in which contamination is likely to occur, by one or more of the following means: location, time, partition, air-flow, enclosed systems, or other effective means. There should be separate or defined areas as follows:

1. An area for the receipt, identification, storage, and withholding from use of components, product containers, closures, and labeling, pending the appropriate sampling, testing, or examination by the quality control unit before release for manufacturing or packaging;
2. An area for the storage of released components, product containers, closures, and labeling;
3. An area for storage of in-process materials;
4. An area for manufacturing and processing operations;
5. An area for packaging and labeling operations; and
6. An area for control and laboratory operations.

Any building used in the manufacture of a dietary ingredient or a dietary supplement shall permit the taking of proper precautions to protect dietary ingredients or dietary supplements in outdoor bulk fermentation vessels by any effective means, including the following:

- (i) Using protective coverings,
- (ii) Controlling areas over and around the vessels to eliminate harborages for pests,
- (iii) Checking on a regular basis for pests and pest infestation, and
- (iv) Skimming the fermentation vessels, as necessary.

Lighting

Adequate lighting shall be provided in all areas and should not expose bulk or finished product to adulteration or contamination. Adequate lighting should be provided in hand-washing areas, dressing and locker rooms, and toilet rooms, and in all areas where product is examined, processed, or stored and where equipment or utensils are cleaned; and such lighting should provide safety-type light bulbs, fixtures, skylights, or other glass suspended over exposed product in any step of preparation or otherwise protect against product adulteration in case of glass breakage.

Ventilation, Air Filtration, Air Heating, and Cooling

Adequate ventilation shall be provided, as well as equipment for adequate control over microorganisms, dust, humidity, and temperature when used in the manufacture of a dietary ingredient and a dietary supplement to minimize odors and vapors (including steam and noxious fumes) in areas where they may adulterate dietary ingredients and dietary supplements; and to locate and operate fans and other air-blowing equipment in a manner that minimizes the potential for adulterating raw materials, in-process or finished dietary ingredients and dietary supplements, or contaminating processing equipment, utensils, or packaging materials.

Plumbing

The plumbing in the physical plant must be of an adequate size and design and be adequately installed and maintained to:

- Carry sufficient amounts of water to the required locations throughout the physical plant;
- Properly convey sewage and liquid disposable waste from the physical plant; and
- Avoid being a source of contamination to components, raw materials, dietary ingredients, dietary supplements, water supplies, or any contact surface, or creating an unsanitary condition.

Potable water at a suitable temperature, and under pressure as needed, should be supplied in a plumbing system free of defects that could contribute contamination to any dietary ingredients and dietary supplements. Potable water should meet the standards prescribed in the Environmental Protection Agency's Primary Drinking Water Regulations (40 CFR Part 141) or any state or local drinking water requirements that are more stringent. Water not meeting such standards should not be permitted in the potable water system for *Purified Water*. If potable water is to be used as a raw material, it should be further purified to satisfy compendial requirements.

Drains should be of adequate size and, where connected directly to a sewer, should have an air break or other mechanical device to prevent back-siphonage.

Sewage and Refuse

Sewage, trash, and other refuse in and from the building and immediate premises shall be disposed of in a safe and sanitary manner.

Washing and Toilet Facilities

Adequate washing facilities shall be provided, including hot and cold water, soap or detergent, air driers or single-service towels, and clean toilet facilities easily accessible to working areas.

General Maintenance and Sanitation

Any building used in the manufacture of a dietary ingredient, a dietary supplement, or both should be maintained in a clean and sanitary condition and shall be kept in repair sufficient to prevent raw materials and in-process or finished dietary ingredients and dietary supplements from becoming adulterated. It shall be free of infestation by rodents, birds, insects, and other vermin. Trash and organic waste matter shall be held and disposed of in a timely and sanitary manner.

Cleaning compounds and sanitizing agents used in cleaning and sanitizing procedures shall be free from undesirable microorganisms and shall be safe and adequate under the conditions of use. Compliance with this requirement may be verified by any effective means, including purchase of these substances under a supplier's guarantee or certification, or examination of these substances for contamination. Only the following toxic materials may be used or stored in a plant where product is processed or exposed:

1. Those required to maintain clean and sanitary conditions;
2. Those necessary for use in laboratory testing procedures;
3. Those necessary for plant and equipment maintenance and operation; and
4. Those necessary for use in the plant's operations.

Written procedures assigning responsibility for sanitation and describing in sufficient detail the cleaning schedules, methods, equipment, and materials to be used in cleaning the building and facilities shall be required.

Toxic cleaning compounds, sanitizing agents, and pesticide chemicals shall be identified, used, held, and stored in a manner that protects against adulteration of raw materials or of in-process or finished product, or contamination of processing equipment or packaging materials. All relevant regulations promulgated by other federal, state, and local government agencies for the application, use or holding of these products should be followed.

No pests shall be allowed in any area of a dietary ingredient manufacturing plant and a dietary supplement manufacturing plant. Effective measures shall be taken to exclude pests from the processing areas and to protect against the adulteration by pests of product on the premises. The use of

insecticides or rodenticides is permitted only under precautions and restrictions that will protect against the adulteration of raw materials, in-process or finished product, or contamination of processing equipment, utensils, or packaging materials.

Written procedures are also required for use of suitable rodenticides, insecticides, fungicides, fumigating agents, and cleaning and sanitizing agents. These procedures should be designed to prevent the contamination of equipment, raw materials, product containers, closures, packaging, labeling materials, or products. Rodenticides, insecticides, and fungicides should be registered and used in accordance with the Federal Insecticide, Fungicide, and Rodenticide Act.

Sanitation procedures shall apply to work performed by contractors or temporary employees as well as work performed by full-time employees during the ordinary course of operations.

EQUIPMENT AND UTENSILS

Equipment and utensils used in the manufacture of dietary ingredients and dietary supplements shall be of appropriate design or selection, adequate size, and suitably located to facilitate operations for its intended use and for its cleaning and maintenance and to ensure that the specifications of dietary ingredients and dietary supplements are correct and are met.

Equipment and utensils include, but are not limited to, the following:

- Equipment used to hold or convey;
- Equipment used to measure;
- Equipment using compressed air or gas;
- Equipment used to carry out processes in closed pipes and vessels; and
- Equipment used in automatic, mechanical, or electronic systems.

Construction

All equipment and utensils shall be:

- Constructed so that surfaces that contact raw materials, in-process materials, or finished products are not reactive, additive, or absorptive so as to alter the safety, identity, strength, quality, or purity of the product beyond the established requirements;
- Made of nontoxic materials;
- Designed and constructed to withstand the environment in which they are used; the action of raw materials, in-process materials, dietary ingredients, or dietary supplements; and, if applicable, cleaning compounds and sanitizing agents; and
- Maintained to protect raw materials, in-process materials, dietary ingredients, and dietary supplements from being contaminated by any source.

Equipment and utensils must have seams that are smoothly bonded or maintained to minimize the accumulation of dirt, filth, organic material, particles of raw materials, in-process materials, dietary ingredients, or dietary supplements, or any other extraneous materials or contaminants, in order to minimize the opportunity for growth of microorganisms.

Each freezer, refrigerator, and cold storage compartment used to hold raw materials, in-process materials, dietary ingredients, or dietary supplements

- Must be fitted with an indicating thermometer, temperature-measuring device, or temperature-recording device that shows, indicates, and records, or allows for recording by hand, the temperature accurately within the compartment; and
- Must have an automated device for regulating temperature or an automated alarm system to indicate a significant temperature change in a manual operation.

The design, construction, and use of equipment and utensils shall preclude the adulteration of raw materials, packaging materials, in-process materials, or finished product with any substances required for operation, such as:

- Lubricants,
- Fuel,
- Coolants,
- Metal or glass fragments,
- Filth or any other extraneous material,
- Contaminated water, or
- Any other contaminants.

Instruments or controls used in the manufacturing, packaging, labeling, or holding of a dietary ingredient, a dietary supplement, or both; and instruments or controls that are used to measure, regulate, or record temperatures, hydrogen-ion concentration (pH), water activity, or other conditions, and to control or prevent the growth of microorganisms or other contamination must be:

- Accurate and precise,
- Adequately maintained, and
- Adequate in number for their designated uses.

For any automated, mechanical, or electronic equipment that is used to manufacture, package, label, or hold a dietary ingredient, a dietary supplement, or both:

- The suitability of the equipment must be determined by ensuring that the equipment is capable of operating satisfactorily within the operating limits required by the process;
- The equipment must be routinely calibrated, inspected, or checked to ensure proper performance. The quality control unit must approve these calibrations, inspections, or checks;
- The appropriate controls for automated, mechanical, and electronic equipment (including software for a computer-controlled process) must be established and used to ensure that any changes to the manufacturing, packaging, labeling, holding, or other operations are approved by the quality control unit and instituted only by authorized personnel; and
- The appropriate controls must be established and used to ensure that the equipment functions in accordance with its intended use. These controls must be approved by the quality control unit.

Compressed air or other gases introduced mechanically into or onto raw materials, in-process materials, dietary ingredients, dietary supplements, or contact surfaces, or that are used to clean any contact surface, must be treated in such a way that the raw material, in-process material, dietary ingredient, dietary supplement, or contact surface is not contaminated.

Cleaning and Maintenance

Equipment and utensils shall be cleaned, maintained, and sanitized at adequate intervals, between the manufacture of different batches of the same product and between the manufacture of different products, to prevent malfunctions or contamination that would alter the safety, identity, strength, quality, or purity of the product beyond the established requirements.

In wet processing during manufacturing, all contact surfaces must be cleaned and sanitized, as necessary, to protect against the introduction of microorganisms into components, dietary ingredients, or dietary supplements. When cleaning and sanitizing is necessary, all contact surfaces must be cleaned and sanitized before use and after any interruption during which the contact surface may have become contaminated.

In a continuous production operation or in back-to-back consecutive operations, which involve different batches of the same dietary ingredient or dietary supplement, the contact surfaces must be adequately cleaned and sanitized.

The surfaces that do not come into direct contact with raw materials, in-process materials, dietary ingredients, or

dietary supplements must be cleaned as frequently as necessary to protect against contaminating raw materials, in-process materials, dietary ingredients, or dietary supplements.

Single-service articles (such as utensils intended for one-time use, paper cups, and paper towels) must be:

- Stored in appropriate containers; and
- Handled, dispensed, used, and disposed of in a manner that protects against contamination of raw materials, in-process materials, dietary ingredients, dietary supplements, or any contact surface.

Cleaning compounds and sanitizing agents must be adequate for their intended use and safe under their conditions of use.

The portable equipment and utensils that have contact surfaces must be cleaned, sanitized, and then stored in a location and manner that protects them from contamination.

Written procedures for cleaning and maintaining equipment, including utensils, used in the manufacture of a product should be established and followed. These procedures should include, but are not necessarily limited to, the following:

- Assignment of responsibility for cleaning and maintaining equipment;
- Maintenance and cleaning schedules, including, where adequate, sanitizing schedules;
- A description in sufficient detail of the methods, equipment, and materials used in cleaning and maintenance operations, and the methods of disassembling and reassembling equipment, as necessary, to ensure proper cleaning and maintenance;
- Removal or obliteration of previous batch identification;
- Identification and protection of clean equipment from contamination before use;
- Inspection of equipment for cleanliness immediately before use;
- Regular calibration and inspection of equipment, or checking machines, to ensure proper performance and function must be conducted:
 - (a) Before first use; and
 - (b) At frequency specified in writing by supporting references.
- Instruments or controls that cannot be adjusted to agree with the reference standard must be repaired or replaced.

A written record of calibration, inspection, maintenance of equipment, and major equipment cleaning and use shall be maintained in individual equipment logs that show the date, product, and lot number of each batch processed. The persons performing the cleaning shall record in the log that the work was performed. Entries in the log should be in chronological order.

The following is specified in order to keep records related to automated, or electric equipment:

- There must be backup file(s) of current software programs (and of outdated software that is necessary to retrieve records that are required to be retained, in accordance with the section *Records and Reports* in this chapter, when current software is not able to retrieve such records) and of data entered into computer systems used to manufacture, package, label, or hold dietary supplements.
 - (a) A backup file (e.g., a hard copy of data entered, diskettes, tapes, microfilm, or compact disks) must be an exact and complete record of the data entered.
 - (b) Backup software programs and data must be kept secure from alterations, inadvertent erasures, or loss.

RAW MATERIALS, PRODUCT CONTAINERS, AND CLOSURES

Written procedures describing in sufficient detail the receipt, identification, storage, handling, sampling, testing, and approval or rejection of raw materials, product containers, and closures should be provided.

Raw materials, product containers, and closures at all times should be handled and stored in a manner to prevent contamination.

Raw agricultural materials that contain soil or other contaminants shall be washed or cleaned as necessary. Water used for washing, rinsing, or conveying raw agricultural materials shall be safe and of adequate sanitary quality. Notwithstanding the general requirement for potable water, water may be reused for washing, rinsing, or conveying raw agricultural materials if it does not increase the level of contamination of such materials.

Bagged or boxed raw materials of product containers or closures should be stored off the floor and suitably spaced to permit cleaning and inspection.

Each lot should be appropriately identified as to its status (i.e., quarantined, approved, or rejected).

Receipt and Storage of Untested Raw Materials, Product Containers, and Closures

Written procedures shall be established and followed describing the receipt, identification, examination, handling, and sampling of raw materials. Upon receipt and before acceptance, each container or grouping of containers of raw materials, product containers, and closures should be examined visually for appropriate labeling as to contents, container damage, or broken seals, and for contamination. They are then stored under quarantine until they have been tested or examined, as appropriate, and released.

Raw materials shall be held in bulk, or in containers designed and constructed so as to protect against adulteration, and shall be held at such temperature and relative humidity and in such a manner as to prevent a dietary ingredient or dietary supplement from becoming adulterated. Frozen raw materials and other ingredients shall be kept frozen. If thawing is required prior to use, it shall be done in a manner that prevents the raw materials and other ingredients from becoming adulterated within the meaning of the Act.

Testing and Approval or Rejection

Each lot of raw materials, product containers, and closures should be sampled, tested, or examined, as appropriate, and released for use by the quality control unit. Based upon adequate process verification, in-process controls and statistical confidence, a skip-lot testing plan is an alternative to fully testing every batch provided that at least one identity test is conducted. An appropriate amount of each lot of raw materials should be reserved for 3 years beyond the shelf life appearing on the label of finished dietary supplements in which the raw materials were used. If adverse event reports are received (see the subsection *Adverse Event Reports*), the reserved raw materials should be kept for 6 years (serious events) or 3 years (nonserious events) from the date the first report is received.

Representative samples should be collected for testing or examination. Sampling of botanicals should be in compliance with the provisions set in *Articles of Botanical Origin* (561). The number of containers sampled, and the amount of material taken from each container, should be based upon appropriate criteria such as statistical criteria for raw material variability, confidence levels, and degree of precision desired, the past quality history of the supplier, and the quantity needed for analysis and reserve where required.

The following procedures should be used to collect the samples:

- The containers of raw materials selected should be cleaned, where necessary, by adequate means.
- The containers should be opened, sampled, and resealed in a manner designed to prevent contamination of their contents and contamination of other raw materials, product containers, or closures.
- These containers should be identified so that the following information can be determined: name of the material sampled, the lot number, the container from which the sample was taken, the date on which the sample was taken, and the name of the person who collected the sample.

Use the following procedure to examine and test the samples:

- At least one test should be conducted to verify the identity of each raw material of a product even in cases where skip-lot testing is used. Such tests may include any appropriate test with established sufficient specificity to determine identity, including chemical and laboratory tests, gross organoleptic analysis, microscopic identification, or analysis of constituent markers.
- Each raw material should be tested for conformity with all appropriate written specifications for purity, strength, and quality. However, a report of analysis may be accepted from the supplier of a raw material, provided that the manufacturer establishes the reliability of the supplier's analyses and provided that at least one identity test is conducted on such raw material by the manufacturer.
- Containers and closures should be tested for conformance with all appropriate written procedures. However, a certificate of testing may be accepted from the supplier, provided that at least a visual identification is conducted on such containers or closures by the manufacturer.
- Each lot of a raw material, rework, product container, or closure that is liable to contamination with filth, insect infestation, or other extraneous adulterant should be examined against established specifications for such contamination and shall comply with any applicable Food and Drug Administration regulations and guidelines. Skip-lot examination should not apply in such cases.
- Each lot of a raw material that is liable to microbiological contamination that is objectionable in view of its intended use shall be subjected to microbiological tests before use. Raw materials either shall not contain levels of microorganisms that may produce food poisoning or other disease in humans, or shall be otherwise treated during manufacturing operations so that they no longer contain levels that would cause the product to be adulterated within the meaning of the Act. In lieu of such testing by the manufacturer, a guarantee or certification of analysis may be accepted from the supplier of a component provided that the manufacturer establishes the reliability of the supplier's analysis.
- Raw materials and other ingredients susceptible to adulteration with aflatoxin, other natural toxins, pesticides, or heavy metals shall comply with current Food and Drug Administration regulations, guidelines, and action levels for poisonous or deleterious substances and the requirements in *Articles of Botanical Origin* (561), or in each monograph, before these materials or ingredients are incorporated into a finished dietary ingredient or dietary supplement. Compliance with this requirement may be accomplished by analyzing these materials and ingredients for aflatoxins and other natural toxins; or, in lieu of such testing by the manufacturer, a guarantee or certification of analysis may be accepted from the supplier of a raw material

provided that the manufacturer establishes the reliability of the supplier's analysis.

- Any lot of raw material, product container, or closure that meets the appropriate written specifications of identity, strength, quality, and purity and related tests may be approved and released for use. Any lot of such material that does not meet such specifications should be rejected.

Use of Approved Raw Materials, Product Containers, and Closures

Raw materials, product containers, and closures approved for use should be rotated so that the oldest approved stock is used first. Deviation from the requirement is permitted if such deviation is temporary and adequate.

Retesting of Approved Raw Materials, Product Containers, and Closures

Raw materials, product containers, and closures should be retested or reexamined, as appropriate, for identity, strength, quality, and purity and approved or rejected by the quality control unit after a specified time in storage or as necessary, e.g., after exposure to air, heat, or other conditions that might adversely affect the raw material, product container, or closure or after storage of active and inactive ingredients and in-process materials for long periods of time.

Rejected Raw Materials, Product Containers, and Closures

Rejected raw materials, product containers, and closures should be identified and controlled under a quarantine system that prevents their use in manufacturing or processing operations for which they are unsuitable.

PRODUCTION AND PROCESS CONTROLS

Written Procedures

Written procedures should be provided for production and process controls designed to ensure that the dietary ingredients and dietary supplements have the identity, strength, quality, and purity they are represented to possess. These procedures should be drafted, reviewed, and approved by the appropriate organizational units and reviewed and approved by the quality control unit. These production and process control procedures should be followed in the execution of the various production and process control functions and should be documented at the time of performance. Any deviation from the written procedures should be recorded and justified.

- (1) All operations in the receiving, inspecting, transporting, segregating, preparing, manufacturing, packaging, and storing of dietary ingredients and dietary supplements shall be conducted in accordance with adequate sanitation principles.
- (2) All reasonable precautions shall be taken to ensure that production procedures do not contribute adulteration from any source. Chemical, microbial, or extraneous-material testing procedures shall be used where necessary to identify sanitation failures or possible product adulteration.
- (3) All product that has become contaminated to the extent that it is adulterated within the meaning of the Act shall be rejected, or if permissible, treated or processed to eliminate the contamination.

- (4) All product manufacturing, including packaging and storage, shall be conducted under such conditions and controls as are necessary to minimize the potential for the growth of microorganisms, or for the adulteration of raw materials, in-process materials, and finished product.
- (5) Measures taken to destroy microorganisms, reduce the microbial load, or prevent the growth of undesirable microorganisms, particularly those of public health significance, shall be adequate under the conditions of manufacture, handling, and distribution to prevent dietary supplements and ingredients from being adulterated within the meaning of the Act. These measures shall also comply with current regulations affecting dietary supplement products and ingredients.
- (6) Work-in-process shall be handled in a manner that protects against adulteration.
- (7) In-process material must be held under appropriate conditions of temperature, humidity, and light.
- (8) Effective measures shall be taken to protect finished dietary ingredients and dietary supplements from adulteration by raw materials, in-process materials, or refuse. When raw materials, in-process materials or refuse are unprotected, they shall not be handled simultaneously in a receiving, loading, or shipping area if that handling could result in adulterated dietary ingredients and dietary supplements. Dietary ingredients and dietary supplements transported by conveyor shall be protected against adulteration as necessary.
- (9) Effective measures shall be taken as necessary to protect against the inclusion of metal or other extraneous material in product. Compliance with this requirement may be accomplished by using sieves, traps, magnets, electronic metal detectors, or other suitable effective means.
- (10) Mechanical manufacturing steps such as cutting, sorting, inspecting, shredding, drying, grinding, blending, and sifting shall be performed so as to protect dietary ingredients and dietary supplements against adulteration. Compliance with this requirement may be accomplished by providing adequate physical protection of dietary ingredients and dietary supplements from contact with adulterants. Protection may be provided by adequate cleaning and sanitizing of all processing equipment between each manufacturing step.
- (11) Heat blanching, when required in the preparation of a dietary ingredient or a dietary supplement, should be effected by heating the product to the required temperature, holding it at this temperature for the required time, and then either rapidly cooling the material or passing it to subsequent manufacturing without delay. Thermophilic growth and contamination in blanchers should be minimized by the use of adequate operating temperatures and by periodic cleaning. Where the blanched product is washed before filling, potable water shall be used.
- (12) Intermediate or dehydrated dietary ingredients and dietary supplements that rely on the control of water (a_w) for preventing the growth of undesirable microorganisms shall be processed to and maintained at a safe moisture level. Compliance with this requirement may be accomplished by any effective means, including employment of one or more of the following practices:
 - (i) Monitoring the water activity (a_w) of the material;
 - (ii) Controlling the soluble solids–water ratio in finished product; and
 - (iii) Protecting finished product from moisture pickup, by use of a moisture barrier or by other means, so that the water activity (a_w) of the product does not increase to an unsafe level.
- (13) Dietary ingredients and dietary supplements that rely principally on the control of pH for preventing the growth of undesirable microorganisms shall be monitored and maintained at an appropriate pH. Compliance with this requirement may be accomplished by any effective means, including employment of one or more of the following practices:
 - (i) Monitoring the pH and water activity, if appropriate, of raw materials, in-process material, and finished product; and
 - (ii) Controlling the amount of acid added to the product.
- (14) When ice is used in contact with dietary ingredients and dietary supplements, it shall be made from potable water, and shall be used only if it has been manufactured in accordance with current good manufacturing practice in manufacturing, packing, or holding human food as outlined in 21 CFR Part 110.

Charge-In of Raw Materials

Written production and control procedures should include the following, which are designed to ensure that the dietary supplements have the identity, strength, quality, and purity they are represented to possess:

- The batch should be formulated with the intent to provide not less than 100 percent of the labeled or established amount of dietary ingredient.
- Raw materials for product manufacturing should be weighed, measured, or subdivided as appropriate and the appropriate signatures recorded in the batch record.
- Actual yields and percentages of theoretical yield should be determined at appropriate phases of processing.

Material scheduled for rework shall be identified as such.

Equipment Identification

All compounding and storage containers, processing lines, and major equipment used during the production of a batch of a product should be properly identified to indicate their contents and, when necessary, the phase of processing of the batch.

Sampling and Testing of In-Process Materials, Dietary Ingredients, and Dietary Supplements

To ensure batch uniformity and integrity of dietary supplements, written procedures should be established and followed that describe the in-process controls and tests or examinations to be conducted on appropriate samples of in-process materials. Based upon process verification, in-process controls, and statistical confidence, a skip-lot testing plan is an alternative to testing every batch of finished products provided that at least one representative measure is performed. Control procedures should be established to monitor the output of those manufacturing processes that may be responsible for causing variability in the characteristics of in-process material and the finished product. Such control procedures may include, but are not limited to, the following, where appropriate:

- Friability
- Weight variation
- Disintegration time
- Dissolution time
- Clarity, completeness, or pH of solutions
- Blend uniformity

In-process specifications for such characteristics should be consistent with finished product specifications. Examination and testing of samples should ensure that the in-process material and dietary supplement conform to the established specifications.

In-process materials should be tested for identity, strength, quality, and purity as adequate, and approved or rejected by the quality control unit during the production process, e.g., at commencement or completion of significant phases or after storage for long periods.

Rejected or adulterated in-process materials should be identified and controlled under a quarantine system designed to prevent their use in manufacturing or processing operations for which they are unsuitable and to prevent the adulteration of other products.

LABELING AND PACKAGING

Materials Examination and Usage Criteria

Written procedures should be provided describing in sufficient detail the receipt, identification, storage, handling, sampling, examination, testing of labeling and packaging materials, or products received for packaging or labeling. Each immediate container or grouping of immediate containers in a shipment of product received for packaging or labeling, or of packaging and labeling materials, must be visually examined for appropriate content label, container damage, or broken seals to determine whether the container condition may have resulted in contamination or deterioration of the received product. The supplier's invoice, guarantee, or certification in a shipment of the received product must be visually examined to ensure that the received product is consistent with the purchase order. Labeling and packaging materials or products received for packaging or labeling should be quarantined until:

- Representative samples of each unique shipment, and of each unique lot within each unique shipment, of received product for packaging or labeling, or of packaging and labeling materials, are collected;
- The quality control unit reviews and approves the documentation to determine whether the received product for packaging or labeling, or packaging and labeling materials, meets the specifications; and
- The quality control unit approves the received product for packaging or labeling, or packaging and labeling materials, and releases for use from quarantine.

Those that do not meet such specifications should be identified and rejected to prevent their use in operations for which they are unsuitable.

A record should be kept of each shipment received of each different labeling and packaging material, or each different received product for packaging or labeling, indicating receipt, date of examination or testing, and whether accepted or rejected.

Each unique lot within each unique shipment of received product for packaging or labeling, or of packaging and labeling materials, must be identified in a manner that allows the recipient to trace the lot to the supplier, the date received, the name of the received product, the status of the received product (e.g., quarantined, approved, or rejected), and to the product that was packaged or labeled and distributed.

This unique identifier must be used whenever the disposition of each unique lot within each unique shipment of the received product for packaging or labeling, or of packaging and labeling materials, is recorded.

Labels and other labeling materials for each different product, strength, product type, or quantity of contents should be stored separately under conditions that will protect against contamination and deterioration and avoid mix-ups. Only authorized personnel should have access to the storage area.

Packaging and labels must be held under appropriate conditions so that the packaging and labels are not adversely affected (e.g. contamination, deterioration).

Gang printing of labeling to be used for different products or different strengths of the same product (or labeling of the same size and identical or similar format or color schemes) should be minimized. If gang printing is employed, packaging and labeling operations should provide for special control procedures, taking into consideration sheet layout, stacking, cutting, and handling during and after printing.

Printing devices on, or associated with, manufacturing lines used to imprint labeling upon the product unit label or case should be monitored to ensure that all imprinting conforms to the print specified in the batch production record.

Obsolete and outdated labels, labeling, other packaging materials, and products received for packaging or labeling should be destroyed and documented.

Labeling Issuance

Strict control should be exercised over labeling issued for use in product labeling operations. The control procedures employed should be in writing with sufficient detail.

Labeling materials issued for a batch should be carefully examined for identity and conformity to the labeling specified in the master and batch production records.

Procedures should be used to reconcile the quantities of labeling issued, used, and returned, and should require evaluation of discrepancies found. If discrepancies are found between the quantity of product finished and the quantity of labeling issued and are outside preset limits based on historical operating data, such discrepancies should be investigated.

Returned labeling should be maintained and sorted in a manner to prevent mixups and provide proper identification.

All excess labeling bearing lot or control numbers should be destroyed and documented.

Operations

Written procedures designed to ensure that correct labels, labeling, and packaging materials are used for dietary supplements should incorporate the following features:

- Prevention of mixups and cross-contamination by physical or spatial separation from operations on other products;
- Identification of the product with a lot or control number;
- Examination of packaging and labeling materials for suitability and correctness before packaging operations, and documentation of such examination in the batch production record; and
- Inspection of the packaging and labeling facilities immediately before use to ensure that all products have been removed from previous operations. Inspection should also be made to ensure that packaging and labeling materials not suitable for subsequent operations have been removed. Results of the inspection should be documented in the batch production records.

Relabeling and Repackaging

- Dietary ingredients and dietary supplements may be repackaged or relabeled only after the quality control unit has approved such repackaging or relabeling.
- A representative sample of each batch of repackaged or relabeled dietary ingredients and dietary supplements must be examined to determine whether the repackaged or relabeled dietary ingredients and dietary supplements meet all established specifications.
- The quality control unit must approve or reject each batch of repackaged or relabeled dietary ingredients

and dietary supplements before its release for distribution.

Tamper-Resistant Packaging

REQUIREMENTS

Each manufacturer and packer who packages a dietary supplement for retail sale shall package the product in a tamper-resistant package, if this product is accessible to the public while held for sale. A tamper-resistant package is one having an indicator or barrier to entry which, if breached or missing, can reasonably be expected to provide visible evidence to consumers that tampering has occurred. To reduce the likelihood of substitution of a tamper-resistant feature after tampering, the indicator or barrier to entry is required to be distinctive by design or by the use of an identifying characteristic (e.g., a pattern, name, registered trademark, logo, or picture). For purposes of this section, the term "distinctive by design" means that the packaging cannot be duplicated with commonly available materials or through commonly available processes. A tamper-resistant package may involve an immediate-container and closure system, or secondary-container or carton system, or any combination of systems intended to provide a visual indication of package integrity. The tamper-resistant feature should be designed to remain intact when handled in a reasonable manner during manufacture, distribution, and retail display.

LABELING

Each retail package of a dietary supplement covered by this section shall bear a statement that is prominently placed so that consumers are alerted to the specific tamper-resistant feature of the package. The labeling statement should be so placed that it will be unaffected if the tamper-resistant feature of the packaging is breached or missing. If the tamper-resistant feature chosen to meet the requirement above is one that uses an identifying characteristic, that characteristic should be referred to in the labeling statement. For example, the labeling statement on a bottle with a shrink band could say "For your protection, this bottle has an imprinted seal around the neck."

Dietary Supplement Examination

Packaged and labeled products should be examined during finishing operations to ensure that containers and packages in the lot have the correct label. A representative sample of units should be collected at the completion of finishing operations and visually examined for correct labeling. Results of these examinations should be recorded in the batch production or control records.

Contact Information

The manufacturer, packer, or distributor of dietary supplements is required to comply with the current labeling requirements in the law that also include a domestic address or phone number through which an adverse event report for a dietary supplement may be received.

Shelf Life

Dietary supplements should bear a date indicative of their shelf life, determined by appropriate testing, to ensure that they meet applicable standards of identity, strength, quality, and purity at or before the labeled shelf-life date.

Shelf life should be related to any storage conditions stated on the labeling.

HOLDING AND DISTRIBUTION

Warehousing Procedures

Storage and transportation of finished product shall be under conditions that will protect product against physical, chemical, and microbial adulteration as well as against deterioration of the product and the container.

Written procedures describing the warehousing of dietary supplements should be established and followed and should include the following:

- Quarantine of finished products before disposition by the quality control unit; and
- Storage of finished products under appropriate conditions of temperature, humidity, and light so that the identity, strength, quality, and purity of the products are not affected.

Distribution Procedures

Written procedures describing the distribution of dietary supplements shall be established and followed and should include the following:

- A procedure whereby the oldest approved stock of a product is distributed first. (Deviation from this requirement is permitted if such deviation is temporary and adequate.)
- A system by which the distribution of each lot of product can be readily determined to facilitate its recall if necessary.

QUALITY CONTROL OPERATIONS

The establishment of any specifications, standards, sampling plans, test procedures, or other laboratory control mechanisms required by this chapter, including any change in such specifications, standards, sampling plans, test procedures, or other laboratory control mechanisms, shall be drafted by the appropriate organizational unit and reviewed and approved by the quality control unit. The requirements in this section should be followed and documented at the time of performance. Any deviation from the written specifications, standards, sampling plans, test procedures, or other laboratory control mechanisms shall be recorded and justified.

Quality control operations include the establishment of scientifically sound and appropriate specifications, standards, sampling plans, and test procedures designed to ensure that raw materials, product containers, closures, in-process materials, labeling, products received for labeling and packaging operations as dietary supplements, and finished products conform to adequate standards of identity, strength, quality, and purity. These controls include the following:

- Determination of conformance to appropriate written specifications for the acceptance of each lot within each shipment of raw materials, product containers, closures, and labeling used in the manufacture of dietary ingredients and dietary supplements, and of products received for labeling and packaging operations as dietary supplements. (The specifications include a description of the sampling and testing procedures used. Samples should be representative and adequately identified. Such procedures also require appropriate retesting of any raw material, product container, or closure that is subject to deterioration.) Based upon adequate process verification, in-process controls, and statistical confidence, a skip-lot testing plan is an alternative to testing every batch, excluding raw materials, which require 100% identity testing.
- Determination of conformance to written specifications and a description of sampling and testing procedures

for in-process materials. (Such samples should be representative and properly identified.)

- Determination of conformance to written descriptions of sampling procedures and appropriate specifications for finished products. (Such samples should be representative and properly identified.)
- The calibration of instruments, at suitable intervals, in accordance with an established written program containing specific directions, schedules, limits for accuracy and precision, and provisions for remedial action in the event that accuracy and/or precision limits are not met. Instruments not meeting established specifications shall not be used until repaired.

Testing and Release for Distribution

There should be appropriate laboratory determination of satisfactory conformance to specifications for the finished product, including the identity and strength prior to release. Based upon adequate process verification, in-process controls, or statistical confidence, a skip-lot or composite testing plan is an alternative to testing every batch.

There should be appropriate laboratory testing, as necessary, of each batch of dietary supplement required to be free of objectionable microorganisms. The accuracy, linearity, sensitivity, specificity, and precision of test methods employed by the firm, when they differ from compendial methods, should be established and documented.

Written procedures should describe any sampling and testing plans, which should include the method of sampling and the number of units per batch to be tested.

Products failing to meet established standards or specifications and any other relevant quality control criteria should be rejected. Rejected or adulterated dietary ingredients and dietary supplements shall be identified, stored, and disposed of in a manner that protects against the adulteration of the other products. Reprocessing may be performed. Prior to acceptance and use, reprocessed material must meet established standards, specifications, and any other relevant criteria. Written procedures shall be established and followed prescribing the method for reprocessing batches or operations start-up materials that do not conform to finished goods standards or specifications. Finished goods manufactured using such materials shall meet all established purity, composition, and quality standards.

Stability Testing

There should be a written protocol designed to assess the stability characteristics of dietary supplements. The results of such testing should be used in determining appropriate storage conditions and shelf life. This protocol should include the following:

- Sample size and test intervals based on statistical criteria for each attribute should be examined to ensure valid estimates of stability;
- Storage conditions for samples retained for testing;
- Reliable, meaningful, and specific test methods should be used; and
- The dietary supplement should be tested in the same type of container-closure system as that in which the dietary supplement is marketed.

An adequate number of batches of each dietary supplement should be tested to determine an adequate shelf life, and a record of these data should be maintained. Accelerated studies combined with basic stability information on the raw materials, dietary supplements, and container-closure systems may be used to support tentative shelf life if full shelf-life studies are not available. Simplified stability testing procedures may be used where data from similar product formulations are available to support a shelf-life estimation of a new product. Where data from accelerated studies are used to project a tentative shelf life date that is beyond a date supported by actual shelf-life studies, stability

studies should be conducted, including dietary supplement testing at appropriate intervals, until the tentative shelf life is verified or the adequate shelf life is determined.

Reserve Samples

An appropriately identified reserve sample that is representative of each lot or batch of dietary supplement should be retained and stored under conditions consistent with product labeling until at least 3 years after the shelf life of the product. The reserve sample should be stored in the same immediate container-closure system in which the finished product is marketed or in one that has essentially the same characteristics. The reserve sample consists of at least twice the quantity necessary to perform all the required tests. If an adverse event report is received, the reserve samples of dietary supplements and dietary ingredients from the same lot or batch must be analyzed by an appropriate procedure to confirm their identity and determine any adulteration or contamination. The recovered samples associated with adverse event reports from consumers, distributors, or both should also be analyzed, following the same method used for the reserved samples, if available. The results should be reported with other required information to the federal authority, using the required form. The reserve samples from a particular lot or batch associated with an adverse event report should be held for 6 years (serious events) or 3 years (nonserious events) from the date when the first adverse event report is received by the manufacturer, packer, or distributor.

RECORDS AND REPORTS

Any record for production, control, quality control operations, or distribution that is required to be maintained and is specifically associated with a batch of a product should be retained for at least 3 years after the shelf life of the batch.

Records should be maintained for all raw materials, product containers, closures, and labeling for at least 3 years after the shelf life of the last lot of product incorporating the raw material or using the container, closure, or labeling.

Master Production and Control Records

To ensure uniformity from batch to batch, master production and control records for each product should be prepared, dated, and signed by one person and independently checked, dated, and signed by a second person from the quality control unit.

Master production and control records should include the following:

- The name and strength of the product;
- The name and weight or measure of each dietary ingredient per unit or portion or per unit of weight or measure of the product, and a statement of the total weight or measure of any dosage unit;
- A complete list of raw materials designated by names or codes sufficiently specific to indicate any special quality characteristic;
- An accurate statement of the weight or measure of each raw material, using the same weight system (metric, avoirdupois, or apothecary) for each raw material;
- A statement concerning any calculated excess of raw material;
- A statement of theoretical weight or measure at appropriate phases of processing;
- A statement of theoretical yield, including the maximum and minimum percentages of theoretical yield beyond which investigation is required;
- A description of the product containers, closures, and packaging materials, including a specimen or copy of each label and all other labeling signed and dated by

- the person or persons responsible for approval of such labeling or, in lieu of specimens or copies of each label or other labeling, a positive identification of all labeling used; and
- Complete manufacturing and control instructions, testing procedures, acceptance limits, special notations, and precautions to be followed.
- Specific actions necessary in order to perform and verify points, steps, or stages in the manufacturing process where control is necessary to ensure the quality of dietary ingredients and dietary supplements, and to ensure that dietary ingredients and dietary supplements are packaged and labeled as specified in the master production record.
 - (a) Such specific actions must include verifying the weight or measure of any component and verifying the addition of any component; and
 - (b) For manual operations, such specific actions must include:
 - (i) One person weighing or measuring a component and another person verifying the weight or measure; and
 - (ii) One person adding the component and another person verifying the addition.
- Corrective action plans for use when a specification is not met.

Batch Production and Control Records

Batch production and control records should be prepared for each batch of product produced and should include complete information relating to the production and control of each batch. These records should be reviewed and signed by a second person from the quality control unit. These records should include accurate reproduction of the appropriate master production or control record and documentation that each significant step in the manufacture, processing, packing, or holding of the batch was accomplished, including the following:

- Dates;
- Identity of individual major equipment and lines used;
- Specific identification of each batch of raw material or in-process material used;
- Weights and measures of raw materials used in the course of processing;
- In-process and laboratory control results;
- Inspection of the packaging and labeling areas before and after use;
- A statement of the actual yield and a statement of the percentage of theoretical yield at appropriate phases of processing;
- Description of product containers and closures used;
- Complete labeling control records, including:
 - (a) The unique identifier assigned to packaging and labels used, the quantity of the packaging and labels used, and, when label reconciliation is required, reconciliation of any discrepancies between issuance and use of labels; and
 - (b) An actual or representative label, or a cross-reference to the physical location of the actual or representative label specified in the master manufacturing record;
- Any sampling performed;
- Identification of the persons performing and directly supervising or checking any step in the operation;
- Any investigation made;
- The results of any tests or examinations conducted on packaged and labeled dietary supplements (including repackaged or relabeled dietary supplements), or a cross-reference to the physical location of such results;
- Documentation at the time of performance that quality control unit:
 - (a) Reviewed the batch production record, including:

- (i) Review of any required monitoring operation, and
- (ii) Review of the results of any tests and examinations, including tests and examinations conducted on components, in-process materials, finished batches of dietary supplements, and packaged and labeled dietary ingredients and dietary supplements;
- (b) Approved or rejected any reprocessing or repackaging;
- (c) Approved and released, or rejected, the batch for distribution, including any reprocessed batch; and
- (d) Approved and released, or rejected, the packaged and labeled dietary supplement, including any repackaged or relabeled dietary supplement;
- Documentation at the time of performance of any required material review and disposition decision; and
- Documentation at the time of performance of any reprocessing.

Records for Raw Materials, Packaging, and Labels and for Product Received for Packaging or Labeling as a Dietary Supplement

The following records must be made and retained:

- Written procedures for fulfilling the requirements for raw materials, packaging, and labels and for product received for packaging or labeling;
- Receiving records (including records such as certificates of analysis, suppliers' invoices, and suppliers' guarantees) for components, packaging, and labels and for products received for packaging or labeling; and
- Documentation that the requirements of *Raw Materials, Labeling and Packaging* were met:
 - (a) The person who performs the required operation must document, at the time of performance, that the required operation was performed; and
 - (b) The documentation must include:
 - (i) The date of receipt of the raw materials, packaging, labels, or products received for packaging or labeling as a dietary supplement;
 - (ii) The initials of the person performing the required operation;
 - (iii) The results of any tests or examinations conducted on raw materials, packaging, or labels, and of any visual examination of product received for packaging or labeling as a dietary supplement; and
 - (iv) Any material review and disposition decision conducted on raw materials, packaging, labels, or products received for packaging or labeling as a dietary supplement.

Laboratory Records

Laboratory records should include complete data derived from all tests necessary to ensure compliance with established specifications and standards, including examinations and assays, as follows:

- A description of the sample received for testing with identification of source (that is, location from where sample was obtained), quantity, lot number or other distinctive code, and date sample was taken.
- A statement of each method used in the testing of the sample.
- A statement of the weight or measure of sample used for each test, where appropriate.
- A complete record of all data secured in the course of each test, including all graphs, charts, and spectra from laboratory instrumentation, properly identified to show the specific raw material, product container,

closure, in-process material, or finished product, and lot tested.

- A record of all calculations performed in connection with the test, including units of measure, conversion factors, and equivalency factors.
- A statement of the results of tests and how the results compare with established standards of identity, strength, quality, and purity for the raw material, product container, closure, in-process material, or finished product tested.
- The initials or signature of the person who performs each test and the date(s) the tests were performed.

Complete records should be maintained of any modification of an established method employed in testing. Such records should include the reason for the modification and data to verify that the modification produced results that are at least as accurate and reliable for the material being tested as the established method.

Complete records should be maintained of any testing and standardization of laboratory reference standards, reagents, and standard solutions, the periodic calibration of laboratory instruments, and all stability testing performed. Any deviation should be reviewed and signed by the management of the quality control unit.

Quality Control Operation Records

The following records must be made and retained:

- Written procedures for the responsibilities of the quality control operations, including written procedures for conducting a material review and making a disposition decision and written procedures for approving or rejecting any reprocessing;
- Written documentation, at the time of performance, that quality control unit performed the review, approval, or rejection requirements, by recording the following:
 - (i) Date on which the review, approval, or rejection was performed; and
 - (ii) Signature of the person performing the review, approval, or rejection; and
- Documentation of any material review and disposition decision and follow-up. Such documentation must be included in the appropriate batch production record and must include:
 - (i) Description of the investigation into the cause of the deviation from the specification or the unanticipated occurrence;
 - (ii) Evaluation of whether the deviation or unanticipated occurrence has resulted in, or could lead to, a failure to ensure the quality of the dietary supplement or a failure to package and label the dietary supplement as specified in the master manufacturing record;
 - (iii) Identification of the action(s) taken to correct, and prevent a recurrence of, the deviation or the unanticipated occurrence;
 - (iv) Explanation of the actions taken with the raw material, dietary supplement, packaging, or label;
 - (v) A scientifically valid reason for any reprocessing of a dietary supplement that is rejected or any treatment or in-process adjustment of a component that is rejected; and
 - (vi) The signatures of (1) the individual(s) designated to perform the quality control operation, who have conducted the material review and made the disposition decision; and in addition, (2) each qualified individual who has provided information relevant to that material review and disposition decision.

Distribution Records

Distribution records should contain the name and strength of the product, name and address of the consignee, date and quantity shipped, and lot or control number of the finished product.

Record Keeping

The manufacturer, packer, or distributor of dietary supplements must keep all required records, as shown in this chapter, for 3 years beyond the shelf life of dietary supplements associated with those records. If adverse event reports are received, those records must be kept for additional 6 years from the date when the first report is received. All records must be accessible by the regulatory authority when requested.

Records must be kept as original records, as true copies (such as photocopies, microfilm, microfiche, or other accurate reproductions of the original records), or as electronic records.

All electronic records must comply with part 11 of Code of Federal Regulations Title 21 (21 CFR part 11).

If reduction techniques are used, such as microfilming, suitable reader and photocopying equipment must be readily available to auditors and inspectors.

Complaint Files

Written procedures describing the handling of all written and oral complaints regarding a dietary supplement shall be established and followed. These procedures should include provisions for review by the quality control unit of any complaint involving the possible failure of a product to meet any of its specifications and a determination as to the need for an investigation.

Each complaint should be recorded in a file designed especially for dietary supplement complaints. Written records should be maintained until at least 3 years after the shelf life of the product, or 3 years after the date when the complaint was received, whichever is longer.

The written record should include the following information, where known: the name and strength of the product, lot number, name of complainant, nature of complaint, and reply to complainant.

If an investigation is necessary, the written record should include the findings of the investigation and follow-up.

The review and investigation of the product complaint by a qualified person, the review by quality control unit about whether to investigate a product complaint, and the findings and follow-up action of any investigation performed must extend to all relevant batches and records.

Adverse Event Reports

Adverse event reports include reports on any health-related adverse event associated with the use of a dietary supplement that is adverse. It includes both nonserious and serious adverse event reports.

The manufacturer, packer, or distributor of a dietary supplement (called the *responsible person*) whose name appears on the label shall be responsible for keeping reports of all nonserious adverse events along with any related records (e.g., records of communications with the person who reported the nonserious event). All such records of nonserious adverse events should be kept for 6 years.

The responsible person whose name appears on the label shall also be responsible for reporting any serious adverse event reported to it, and associated with a dietary supplement that is marketed and used in the same country, to the regulatory authority as soon as appropriate, but no later than 15 business days after receipt of the report, using the

appropriate form as defined by the regulation (<http://www.fda.gov/Food/DietarySupplements/Alerts/ucm111110.htm>). A serious adverse event is an event that results in any of the following:

1. Death,
2. A life-threatening experience,
3. Inpatient hospitalization,
4. A persistent or significant disability or inability,
5. A congenital anomaly or birth defect, or
6. A condition that requires, according to reasonable medical judgment, a medical or surgical intervention to prevent one of the five outcomes listed above.

A retailer whose name appears on the label as a distributor may, by agreement, authorize the manufacturer or packer to submit the required reports to the regulatory authority, as long as the retailer directs all received adverse event reports to the manufacturer or packer. Each serious adverse event report should include a copy of the product's label, the information described in the preceding section *Complaint Files*, and if possible, the contact information of the complainant; daily intake; alcohol consumption and amount; use of prescription medicine and OTC medicine, including a daily dose; and other medical information. The information associated with personal identification and medical records should be obtained only for the reports and kept safe from disclosure. Any new medical information that is related to an already submitted serious adverse event report that is received within 1 year of the initial report shall be submitted to the regulatory authority as soon as appropriate, but no later than 15 business days after receipt of the information. The records related to each report of a serious adverse event received by the manufacturer, packer, or retailer should be maintained for 6 years. The authorized person who is designated by the regulatory authority should be permitted access to those records.

RETURNED AND SALVAGED PRODUCTS

Returned Dietary Supplements

Returned products should be identified as such and held. If the conditions under which returned dietary ingredients and dietary supplements have been held, stored, or shipped before or during their return, or if the condition of the product, its container, carton, or labeling, as a result of storage or shipping, casts doubt on the safety, identity, strength, quality, or purity of the product, the returned product should be destroyed unless examination, testing, or other investigations prove the product meets appropriate standards of safety, identity, strength, quality, or purity. The returned products associated with adverse events must be destroyed after a sufficient sample of products is stored for the purpose of further investigation only. The products related to the adverse event that have been returned should be kept for 6 years (serious events) or 3 years (nonserious events) from the date when the first report is received. A product may be reprocessed provided that the subsequent product meets adequate standards, specifications, and characteristics. Records of returned products should be maintained and should include the name and label potency of the product, lot number (or control number or batch number), reason for the return, quantity returned, date of disposition, and ultimate disposition of the returned product. If the reason for a product being returned implicates associated batches, an appropriate investigation is necessary.

Dietary Supplement Salvaging

Products that have been involved in adverse events or subjected to improper storage conditions, including extremes in temperature or humidity, smoke, fumes, pressure, age, or radiation due to natural disasters, fires, accidents, or

equipment failures should not be salvaged and returned to the marketplace. Whenever there is a question whether products have been subjected to such conditions, salvaging operations may be conducted only if there is (a) evidence from laboratory tests and assays that the products meet all applicable standards of identity, strength, quality, and purity, and (b) evidence that the products and their associated packaging were not subjected to improper storage conditions as a result of the disaster or accident. Organoleptic examinations should be accepted only as supplemental evidence that the dietary supplement meets appropriate standards of identity, strength, quality, and purity. Records including name, lot number, and disposition should be maintained for salvaged products. If the products are involved in adverse events, the instructions described in the preceding section *Records and Reports* should be followed.

Defect Action Levels

Some dietary ingredients and dietary supplements, even when produced under current good manufacturing practice, contain natural or unavoidable defects that at low levels are not hazardous to health. The Food and Drug Administration establishes maximum levels for these defects in dietary ingredients and dietary supplements produced under current good manufacturing practice and uses these levels in deciding whether to recommend regulatory action.

Defect action levels are established for dietary ingredients and dietary supplements whenever it is necessary and feasible to do so. These levels are subject to change upon the development of new technology or the availability of new information.

Compliance with defect action levels does not excuse violation of the requirement in section 402(a)(4) of the Act that dietary ingredients and dietary supplements shall not be prepared, packed, or held under unsanitary conditions or the requirements in this part that manufacturers, distributors, and holders of both dietary ingredients and dietary supplements shall observe current good manufacturing practice. Evidence indicating that such a violation exists causes a dietary ingredient and a dietary supplement to be adulterated within the meaning of the Act, even though the amounts of natural or unavoidable defects are lower than the currently established defect action levels. The manufacturer, distributor, and holder of a dietary ingredient or a dietary supplement shall at all times utilize quality control operations that reduce natural or unavoidable defects to the lowest level currently feasible.

The mixing of a dietary ingredient or dietary supplement containing defects above the current defect action level with another lot of dietary ingredient or dietary supplement is not permitted and renders the final product adulterated within the meaning of the Act, regardless of the defect level of the final product.

A compilation of the current defect action levels for natural or unavoidable defects in dietary ingredients and dietary supplements that present no health hazard may be obtained upon request from the Industry Activities Staff (HFS-565), Center for Food Safety and Applied Nutrition, U.S. Food and Drug Administration, 5100 Paint Branch Parkway, College Park, MD 20740-3835.

GLOSSARY

Act means Federal Food, Drug and Cosmetic Act (United States Code [U.S.C.] Title 21, Chapter 9).

Acceptance criteria are the product specifications and acceptance or rejection criteria, such as acceptable quality level and unacceptable quality level, with an associated sampling plan, that are necessary for making a decision to accept or reject a lot or batch (or any other convenient subgroups of manufactured units).

Adequate means that which is needed to accomplish the intended purpose in keeping with good public health practice.

Adverse event means any health-related event that is adverse and that is associated with the use of a dietary supplement.

Adverse event report means a report of an adverse event (see definition above). (See also *Serious adverse event report*.)

Batch is a specific quantity of a finished product or other material that is intended to have uniform character and quality, within specified limits, and is produced according to a single manufacturing order during the same cycle of manufacture.

Blanching means a prepackaging heat treatment of a dietary ingredient and a dietary supplement for a sufficient time and at a sufficient temperature to partially or completely inactivate the naturally occurring enzymes and to effect other physical or biochemical changes in the product.

Composition is (1) the identity of a dietary ingredient or dietary supplement, and (2) the concentration of a dietary ingredient (e.g., weight or other unit of use/weight or volume), or the potency or activity of one or more dietary ingredients, as indicated by appropriate procedures.

Dietary ingredient is an ingredient intended for use or used in a dietary supplement that is

- a vitamin;
- a mineral;
- an herb or other botanical;
- an amino acid;
- a dietary substance for use by humans to supplement the diet by increasing the total dietary intake, or a concentrate, metabolite, constituent, extract; or
- a combination of any of the foregoing ingredients.

Dietary supplement is a product (other than tobacco) that is intended to supplement the diet and that bears or contains one or more of the following dietary ingredients: a vitamin, a mineral, an herb or other botanical, an amino acid, a dietary substance for use by humans to supplement the diet by increasing the total daily intake, or a concentrate, metabolite, constituent, extract or combination of these ingredients, that is intended for ingestion in a pill, capsule, tablet or liquid form, that is not represented for use as a conventional food or as the sole item of a meal or diet, and that is labeled as a dietary supplement, and includes products such as new drug, certified antibiotic, or licensed biologic that was marketed as a dietary supplement or food before approval, certification, or license unless a sanitary authority waives this provision.

Inactive ingredient is any raw material other than a dietary ingredient.

In-process material is any material fabricated, compounded, blended, ground, extracted, sifted, sterilized, or processed in any other way that is produced for, and used in, the preparation of the dietary supplement.

Lot is a batch, or a specific identified portion of a batch, having uniform character and quality within specified limits.

Lot number, control number, or batch number is any distinctive combination of letters, numbers, or symbols, or any combination of them from which the complete history of the manufacture, processing, packing, holding, and distribution of a batch or lot of finished dietary ingredient, dietary supplement, or other material can be determined.

Manufacture or manufacturing includes all operations associated with the production of dietary ingredients and dietary

supplements, including packaging and labeling operations, testing, and quality control of a dietary ingredient or dietary supplement.

Microorganisms means yeast, molds, bacteria, and viruses and includes, but is not limited to, species having public health significance. The term “undesirable microorganisms” includes those microorganisms that are of public health significance, that subject a dietary ingredient or a dietary supplement to decomposition, that indicate that a dietary ingredient or dietary supplement is contaminated with filth, or that otherwise may cause a dietary ingredient or a dietary supplement to be adulterated within the meaning of the Act. Occasionally in these regulations, the adjective “microbial” is used instead of an adjectival phrase containing the word “microorganism.”

Pest refers to any objectionable animals or insects including, but not limited to, bird, rodents, flies, and larvae.

Plant means the building or facility or parts thereof, used for or in connection with the manufacturing, packaging, labeling, or holding of a dietary ingredient and a dietary supplement.

Process evaluation is a set of tests performed on a process intended to evaluate its capacity to consistently produce the results that it is intended for.

Quality control operation is a planned and systematic procedure for taking all actions necessary to prevent a dietary ingredient and a dietary supplement from being adulterated.

Quality control unit is any person or organizational element designated by the firm to be responsible for the duties relating to quality control operations.

Raw material is any ingredient intended for use in the manufacture of a dietary ingredient or dietary supplement, including those that may not appear in such finished product. (A dietary ingredient is a raw material when considering the manufacture of a dietary supplement.)

Representative sample is a sample that consists of a number of units that are drawn based on rational criteria such as random sampling and is intended to ensure that the sample accurately portrays the material being sampled.

Rework is a clean, unadulterated material that has been removed from processing for reasons other than unsanitary conditions or that has been successfully reconditioned by reprocessing and that is suitable for use in the manufacture of a dietary ingredient or a dietary supplement.

Sanitizing is to adequately treat equipment, containers, or utensils by a process that is effective in destroying vegetative cells of microorganisms of public health significance and in substantially reducing other undesirable microorganisms but without affecting the product or its safety for the consumer.

Serious adverse event report means a report of an adverse event that is termed *serious* because it meets certain criteria (see the subsection *Adverse Event Reports*). The Dietary Supplement and Nonprescription Drug Consumer Protection Act requires manufacturers and distributors of dietary supplements and OTC drugs to report all serious adverse events to the Secretary of the Food and Drug Administration (FDA). This is an entirely new requirement for dietary supplements.

Shall is used to state requirements that must be met under the provisions of this guideline.

Shelf life is the period of time after manufacturing in which the dietary supplement is ensured to meet applicable standards of identity, strength, quality, and purity.

Shelf-life (Use by) date is the date beyond which the dietary supplement is no longer ensured to meet applicable standards of identity, strength, quality, and purity.

Should is used to state recommended or advisory procedures or identify recommended equipment.

Skip-lot testing (or sampling) is a reduced level of testing (or sampling) for a particular specified parameter(s) based upon one or more of the following:

- Statistical analysis of an adequate quantity of historical test data;

- Statistical confidence in the capability of the manufacturing process as determined by suitable verification; or

- Ongoing monitoring of the process using recognized statistical process control (SPC) techniques.

Strength means the concentration of the active substance (weight/weight, weight/volume, or unit of use/volume or weight basis); and/or the potency, that is, the activity of the product as indicated by appropriate laboratory tests.

Water activity (a_w) is a measure of the free moisture in a dietary ingredient or dietary supplement and is the quotient of the water vapor pressure of the substance divided by the vapor pressure of pure water at the same temperature.

Reagents, Indicators and Solutions

This section deals with the reagents and solutions required in conducting the Pharmacopeial and the National Formulary tests and assays.

As is stated in the *General Notices*, listing of reagents, indicators, and solutions in the Pharmacopeia in no way implies that they have therapeutic utility; thus, any reference to the USP in their labeling is to include the term "reagent" or "reagent grade."

Reagents required in the tests and assays for the Pharmacopeial and National Formulary articles are listed in this section, generally with specifications appropriate to their intended uses. Exceptions to the latter include those reagents for which corresponding specifications are presented in the current edition of *Reagent Chemicals*, published by the American Chemical Society, and reagents for which specifications could not be drafted in time for inclusion here. Thus, where it is directed to "Use ACS reagent grade," it is intended that a grade meeting the corresponding specifications of the current edition of *ACS Reagent Chemicals* shall be used. Where no such specifications exist, and where it is directed to "Use a suitable grade," the intent is that a suitable reagent grade available commercially shall be used. Occasionally, additional test(s) augment the designation "suitable grade," as indicated in the text. Listed also are some, but not all, reagents that are required only in determining the quality of other reagents. For those reagents that are not listed, satisfactory specifications are available in standard reference works.

In those instances in which a reagent required in a Pharmacopeial or National Formulary test or assay need not be of analytical reagent quality, it suffices to refer to the monograph for that article appearing in this Pharmacopeia or the National Formulary or the current edition of the Food Chemicals Codex (FCC). In such cases it is to be understood that the specifications are minimum requirements and that any substance meeting more rigid specifications for chemical purity is suitable.

Where the name of a reagent specified in a test or assay is the same as the title of a USP or NF article, and it does not appear among the following *Reagent Specifications*, a substance meeting the requirements of the USP or NF monograph is to be used (e.g., *Benzocaine*, USP; or *Propylparaben*, NF). However, reference is specifically made, under *Reagent Specifications*, to a reagent bearing the name of a USP or NF article: (1) where there are requirements for a reagent in addition to the USP or NF monograph requirements (e.g., *Sodium Salicylate*, USP; or *Isopropyl Myristate*, NF), (2) where a source other than the USP or NF monograph is specified (e.g., *Lactose*, ACS reagent; or *Hydrochloric Acid*, ACS reagent), (3) where complete reagent specifications differ from the USP or NF monograph standards (e.g., *Calcium Lactate*; or *Thymol*), or (4) where a standard material is included among the reagent specifications (e.g., *Calcium Carbonate*, primary standard; or *Sodium Carbonate*, primary standard).

Reagents and solutions should be preserved in tight containers made of resistant glass or other suitable material. Directions for storage in light-resistant containers should be carefully observed.

Stoppers and stopcocks brought into contact with substances capable of attacking or penetrating their surfaces may be given a protective coating of a thin film of a suitable lubricant unless specifically interdicted.

Where a particular brand or source of a material or piece of equipment, or the name and address of a manufacturer, is mentioned, this identification is furnished solely for informational purposes as a matter of convenience, without implication of approval, endorsement, or certification.

Atomic absorption and flame photometry require the use of a number of metal-ion standard solutions. While the individual monographs usually provide directions for preparation of these solutions, use of commercially prepared standardized solutions of the appropriate ions is permissible, provided that the analyst confirms the suitability of the solutions and has data to support their use.

Reagents are substances used either as such or as constituents of solutions.

Indicators are reagents used to determine the specified endpoint in a chemical reaction, to measure hydrogen-ion concentration (pH), or to indicate that a desired change in pH has been effected. They are listed together with indicator test papers.

Buffer Solutions are referred to separately.

Colorimetric Solutions, abbreviated "CS," are solutions used in the preparation of colorimetric standards for comparison purposes.

Test Solutions, abbreviated "TS," are solutions of reagents in such solvents and of such definite concentrations as to be suitable for the specified purposes.

Volumetric Solutions, abbreviated "VS" and known also as **Standard Solutions**, are solutions of reagents of known concentration intended primarily for use in quantitative determinations. Concentrations are usually expressed in terms of normality.

Water—As elsewhere in the Pharmacopeia, where "water", without qualification, is mentioned in the tests for reagents or in directions for preparing test solutions, etc., Purified Water (USP monograph) is always to be used. *Carbon dioxide-free water* is Purified Water that has been boiled vigorously for 5 minutes or more and allowed to cool while protected from absorption of carbon dioxide from the atmosphere, or Purified Water that has a resistivity of not less than 18 Mohm-cm. *Deaerated water*, for purposes other than dissolution and drug release testing, is Purified Water that has been treated to reduce the content of dissolved air by suitable means, such as by boiling vigorously for 5 minutes and cooling or by the application of ultrasonic vibration. *Particle-free water* is water that has been passed through a 0.22- μ m filter.

Organic-free water is Purified Water that produces no significantly interfering peaks when chromatographed as it is indicated in *Identification*, *Control*, and *Quantification of Residual Solvents* under *Residual Solvents* (467).

Chromatographic Solvents and Carrier Gases—The chromatographic procedures set forth in the Pharmacopeia may require use of solvents and gases that have been especially purified for such use. The purpose may be (a) to exclude certain impurities that interfere with the proper conduct of the test procedure, or (b) to extend the life of a column by reducing the build-up of impurities on the column. Where solvents and gases are called for in chromatographic procedures, it is the responsibility of the analyst to ensure the suitability of the solvent or gas for the specific use. Solvents and gases suitable for specific high-pressure or other chromatographic uses are available as specialty products from various reagent supply houses, although there is

no assurance that similar products from different suppliers are of equivalent suitability in any given procedure. The reagent specifications provided herein are for general analytical

uses of the solvents and gases and not for chromatographic uses for which the especially purified specialty products may be required.

Reagents

For the purposes of the following specifications, these definitions apply: A *blank* consists of the same quantities of the same reagents treated in the same manner as the specimen under test. A *control* is a blank to which has been added the limiting quantity of the substance being tested for, or is a specified comparison solution prepared as directed in the particular test.

The values given in boldface type following chemical symbols and formulas represent, respectively, atomic and molecular weights of the substances concerned.

Color and turbidity comparisons are to be made in color-comparison tubes that are matched as closely as possible in internal diameter and in all other respects, as directed for *Visual Comparison* under *Spectrophotometry and Light-scattering* (851). Such tubes frequently are called "Nessler tubes."

In making visual comparisons of the densities of turbid fluids, compensate for differences in color, if necessary, by viewing the turbidity through a column of water, the depth of which is determined by the volume specified in the individual reagent specification. Place the water in color-comparison tubes, and hold one of the tubes above the control tube and the other below the specimen tube.

Where an expression such as "Retain the filtrate" appears it is to be understood, unless otherwise indicated, that the washings of the residue are not to be added to the filtrate obtained. In the test heading, *Calcium, magnesium, and R₂O₃ precipitate*, the expression *R₂O₃* is intended to indicate the residue on ignition from compounds precipitated upon the addition of ammonium hydroxide, such as *Fe₂O₃* and *Al₂O₃*.

GENERAL TESTS FOR REAGENTS

The following general test methods are provided for the examination of reagents to determine their compliance with the specifications of the individual reagents and are to be used unless it is otherwise directed in such specifications.

Boiling or Distilling Range for Reagents

Use the following procedure for determining the boiling or distilling range of reagents, unless otherwise directed in the individual specifications:

APPARATUS—Use apparatus similar to that specified for *Distilling Range—Method I* (721), except that the distilling flask is to be of 250-mL capacity, to have a short neck, and to be connected to the condenser by means of a three-way connecting tube fitted with standard-taper ground joints.

PROCEDURE—Place the distilling flask in an upright position in the perforation in the asbestos board, and connect it to the condenser.

Measure 100 mL of the liquid to be tested in a graduated cylinder, and transfer to the boiling flask together with some device to prevent bumping. Use the cylinder as the receiver for the distillate. Insert the thermometer, and heat so as to distill at the rate of 3 mL to 5 mL per minute. Make a preliminary trial, if necessary, to determine the adjustment for the proper rate of heating. Read the thermometer when about 20 drops have distilled and thereafter at volumes of distillate of 5, 10, 40, 50, 60, 90, and 95 mL. Continue the distillation until the dry point is reached.

The *Boiling or Distilling Range* is the interval between the temperatures when 1 mL and 95 mL, respectively, have distilled.

Arsenic in Reagents

Select reagents for this test for a low arsenic content, so that a blank test results in either no stain or one that is barely perceptible.

APPARATUS—Prepare a generator by fitting a 1-hole rubber stopper into a wide-mouth bottle of about 60-mL capacity. Through the perforation insert a vertical exit tube about 12 cm in total length and 1 cm in diameter along the entire upper portion (for about 8 cm) and constricted at its lower extremity to a tube about 4 cm in length and about 5 mm in diameter. The smaller portion of the tube should extend to just slightly below the stopper. Place washed sand or a pledget of purified cotton in the upper portion to about 3 cm from the top of the tube. Moisten the sand or cotton uniformly with lead acetate TS, and remove any excess or adhering droplets of the latter from the walls of the tube. Into the upper end of this tube fit a second glass tube 12 cm in length, having an internal diameter of 2.5 to 3 mm, by means of a rubber stopper. Just before running the test, place a strip of mercuric bromide test paper (see under *Indicator and Test Papers*) in this tube, crimping the upper end of the strip so that it will remain in position about 2 cm above the rubber stopper. Clean and dry the tube thoroughly each time it is used.

STANDARD ARSENIC SOLUTION—Use *Standard Preparation* prepared as directed under *Arsenic* (211).

TEST PREPARATION—Add 1 mL of sulfuric acid to 5 mL of a solution of the chemical substance (1 in 25), unless another quantity is directed in the individual reagent specification. Omit its addition entirely in the case of inorganic acids. Unless especially directed otherwise, add 10 mL of sulfurous acid. Evaporate the liquid in a small beaker, on a steam bath, until it is free from sulfurous acid and has been reduced to about 2 mL in volume. Dilute with water to 5 mL to obtain the *Test Preparation*. Substances subjected to special treatments specified in the individual reagent specification may be used directly as the *Test Preparation*.

[NOTE—Solutions prepared by the dissolving of the chemical substances in dilute acids are not considered to have undergone special treatment.]

STANDARD STAIN—Place in the generator bottle 5 mL of potassium iodide TS, 2.0 mL of *Standard Arsenic Solution*, 5 mL of acid stannous chloride TS, and 28 mL of water. Add 1.5 g of granulated zinc (in No. 20 powder), and immediately insert the stopper containing the exit tube. Keep the generator bottle immersed in water at 25° during the period of the test to moderate the reaction so that the stain will take the form of a distinctive band to facilitate the comparison of color intensity. When evolution of hydrogen has continued for 1 hour, remove the mercuric bromide test paper for comparison. This stain represents 2 µg of arsenic.

PROCEDURE—Pipet into the generator bottle 5 mL of potassium iodide TS and 5 mL of the *Test Preparation*, and add 5 mL of acid stannous chloride TS. Set the apparatus aside at room temperature for a period of 10 minutes, then add 25 mL of water and 1.5 g of granulated zinc (in No. 20 powder), and proceed as directed under *Standard Stain*. Remove the mercuric bromide test paper, and compare the stain upon it with the *Standard Stain*: the stain produced by the chemical tested does not exceed the standard stain in length or in intensity of color, indicating not more than 10 parts of arsenic per million parts of the substance being tested. Since light, heat, and moisture cause the stain to

fade rapidly, place the papers in clean, dry tubes, and make comparisons promptly.

INTERFERING CHEMICALS—*Antimony*, if present in the substance being tested, produces a gray stain. *Sulfites*, *sulfides*, *thiosulfates*, and other compounds that liberate hydrogen sulfide or sulfur dioxide when treated with sulfuric acid must be oxidized by means of nitric acid and then reduced by means of sulfur dioxide as directed under *Test Preparation* before they are placed in the apparatus. Certain *sulfur compounds*, as well as *phosphine*, give a bright yellow band on the test paper. If *sulfur compounds* are present, the lead acetate-moistened cotton or sand will darken. In that case, repeat the operation as directed under *Test Preparation* upon a fresh portion of the solution being tested and use greater care in effecting the complete removal of the sulfurous acid. In testing hypophosphites, observe special care to oxidize completely the solution being tested as directed, otherwise the evolution of phosphine may result in a yellow stain which may be confused with the orange-yellow color produced by arsine. The stain produced by phosphine may be differentiated from that given by arsine by means of moistening it with 6 N ammonium hydroxide. A stain caused by arsine becomes dark when so treated, but a stain produced by phosphine does not materially change in color.

Chloride in Reagents

STANDARD CHLORIDE SOLUTION—Dissolve 165.0 mg of dried sodium chloride in water to make 1000.0 mL. This solution contains the equivalent of 0.10 mg of chlorine (Cl) in each mL.

PROCEDURE—Neutralize, if alkaline, a solution of the quantity of the reagent indicated in the test in 25 mL of water, or a solution prepared as directed in the test, with nitric acid, litmus paper being used as the indicator, and add 3 mL more of nitric acid. Filter the solution, if necessary, through a filter paper previously washed with water until the paper is free from chloride, and add 1 mL of silver nitrate TS. Mix, and allow to stand for 5 minutes protected from direct sunlight. Compare the turbidity, if any, with that produced in a control made with the same quantities of the same reagents as in the final test and a volume of *Standard Chloride Solution* equivalent to the quantity of chloride (Cl) permitted by the test. Adjust the two solutions with water to the same volume before adding the silver nitrate TS, and compare the turbidities.

In *testing barium salts*, neutralize, if alkaline, the solution containing the reagent, with nitric acid, and add only 3 drops more of nitric acid. Conduct the remainder of the test as described previously.

In *testing salts giving colored solutions*, dissolve 2 g of the reagent in 25 mL of water, and add 3 mL of nitric acid. Filter the solution, if necessary, through a filter paper previously washed with water, and divide the filtrate into two equal portions. Treat one portion with 1 mL of silver nitrate TS, allow to stand for 10 minutes, and, if any turbidity is produced, filter it through a washed filter paper until clear, and use the filtrate as a blank. Treat the other portion with 1 mL of silver nitrate TS, mix, and allow to stand for 5 minutes protected from direct sunlight. Compare the turbidity with that produced in the blank by the addition of a volume of *Standard Chloride Solution* equivalent to the quantity of chloride (Cl) permitted in the test, both solutions being adjusted with water to the same volume.

Flame Photometry for Reagents

The use of flame photometric procedures to determine traces of calcium, potassium, sodium, and strontium is called for in some of the reagent specifications. The suitability of such determinations depends upon the use of adequate apparatus, and several instruments of suitable selectiv-

ity are available. The preferred type of flame photometer is one that has a red-sensitive phototube, a multiplier phototube, a monochromator, an adjustable slit-width control, a selector switch, and a sensitivity control. Other types of photometers may be used, provided the operator has proved that the instrument will determine accurately the amount of impurities permitted in the reagent to be tested.

The flame photometric procedures depend upon the use of semi-internal standards, and thus require both a *Sample Solution* and a *Control Solution*. For the *Sample Solution*, a specified weight of specimen is dissolved and diluted to a definite volume. For the *Control Solution*, the same amount of specimen is dissolved, the limiting amounts of the suspected impurities are added, and the solution is then diluted to the same definite volume as the *Sample Solution*. The flame photometer is set as directed in the general procedures and then adjusted to give an emission reading as near 100% transmittance as is possible with the *Control Solution* at the wavelength specified for the particular impurity concerned. With the instrument settings left unchanged, the emission from the *Sample Solution* is read at the same wavelength and at a specified background wavelength. The background reading is then used to correct the observed emission of the *Sample Solution* for the emission due to the specimen and the solvent. The specimen being tested contains less than the specified limit of impurity if the difference between the observed background and total emissions for the *Sample Solution* is less than the difference between the observed emissions for the *Control Solution* and the *Sample Solution* at the wavelength designated for the particular impurity.

CALCIUM IN REAGENTS

Standard Calcium Solution—Dissolve 250 mg of calcium carbonate in a mixture of 20 mL of water and 5 mL of diluted hydrochloric acid, and when solution is complete, dilute with water to 1 L. This solution contains 0.10 mg of calcium (Ca) per mL.

Procedure—Use the *Sample Solution* and the *Control Solution* prepared as directed in the individual test procedure.

Set the slit-width control of a suitable flame photometer at 0.03 mm, and set the selector switch at 0.1. Adjust the instrument to give the maximum emission with the *Control Solution* at the 422.7-nm calcium line, and record the transmittance. Without changing any of the instrument settings, record the transmittance for the emission of the *Sample Solution* at 422.7 nm. Change the monochromator to the wavelength specified in the individual test procedure, and record the background transmittance for the background emission of the *Sample Solution*: the difference between the transmittances for the *Sample Solution* at 422.7 nm and at the background wavelength is not greater than the difference between transmittances observed at 422.7 nm for the *Sample Solution* and the *Control Solution*.

POTASSIUM IN REAGENTS

Standard Potassium Solution—Dissolve 191 mg of potassium chloride in a few mL of water, and dilute with water to 1 L. Dilute a portion of this solution with water in the ratio of 1 to 10 to obtain a concentration of 0.01 mg of potassium (K) per mL.

Procedure—Use the *Sample Solution* and the *Control Solution* prepared as directed in the individual test procedure.

[NOTE—In testing calcium salts, use an oxyhydrogen burner.]

Set the slit-width control of a suitable flame photometer equipped with a red-sensitive detector at 0.1 mm, unless otherwise directed, and set the selector switch at 0.1. Adjust the instrument to give the maximum emission with the *Control Solution* at the 766.5-nm potassium line, and record the transmittance. Without changing any of the instrument settings, record the transmittance for the emission of the *Sample Solution* at 766.5 nm. Change the monochromator to 750 nm, and record the background transmittance for the background emission of the *Sample Solution*: the difference

between the transmittances for the *Sample Solution* at 766.5 nm and 750 nm is not greater than the difference between transmittances observed at 766.5 nm for the *Sample Solution* and the *Control Solution*.

SODIUM IN REAGENTS—

Standard Sodium Solution—Dissolve 254 mg of sodium chloride in a few mL of water, and dilute with water to 1 L. Dilute a portion of this solution with water in the ratio of 1 to 10 to obtain a concentration of 0.01 mg of sodium (Na) per mL.

Procedure—Use the *Sample Solution* and the *Control Solution* prepared as directed in the individual test procedure.

Set the slit-width control of a suitable flame photometer at 0.01 mm, and set the selector switch at 0.1. Adjust the instrument to give the maximum emission with the *Control Solution* at the 589-nm sodium line, and record the transmittance. Without changing any of the instrument settings, record the transmittance for the emission of the *Sample Solution* at 589 nm. Change the monochromator to 580 nm, and record the background transmittance for the background emission of the *Sample Solution*: the difference between the transmittances for the *Sample Solution* at 589 and 580 nm is not greater than the difference between transmittances observed at 589 nm for the *Sample Solution* and the *Control Solution*.

STRONTIUM IN REAGENTS—

Standard Strontium Solution—Dissolve 242 mg of strontium nitrate in a few mL of water, and dilute with water to 1 L. Dilute a portion of this solution with water in the ratio of 1 to 10 to obtain a concentration of 0.01 mg of strontium (Sr) per mL.

Procedure—Use the *Sample Solution* and the *Control Solution* prepared as directed in the individual test procedure.

Set the slit-width control of a suitable flame photometer at 0.03 mm, and set the selector switch at 0.1. Adjust the instrument to give the maximum emission with the *Control Solution* at the 460.7-nm strontium line, and record the transmittance. Without changing any of the instrument settings, record the transmittance for the emission of the *Sample Solution* at 460.7 nm. Change the monochromator to the wavelength specified in the individual test procedure, and record the background transmittance for the background emission of the *Sample Solution*: the difference between the transmittances for the *Sample Solution* at 460.7 nm and at the background wavelength is not greater than the difference between transmittances observed at 460.7 nm for the *Sample Solution* and the *Control Solution*.

Heavy Metals in Reagents

STANDARD LEAD SOLUTION—Use *Standard Lead Solution* (see *Heavy Metals* (231)). Each mL of this solution contains the equivalent of 0.01 mg of Pb.

PROCEDURE—Unless otherwise directed, test for heavy metals as follows:

(a) If the heavy metals limit is 0.0005% (5 ppm), dissolve 6.0 g of the specimen in water to make 42 mL.

(b) If the heavy metals limit is 0.001% (10 ppm) or more, or in the event of limited solubility, use 4 g, and dissolve in water to make 40 mL, warming, if necessary, to aid solution.

For the control, transfer 7 mL of the solution from (a) to a color-comparison tube, and add a volume of *Standard Lead Solution* equivalent to the amount of lead permitted in 4 g of the reagent. Dilute with water to 35 mL, and add diluted acetic acid, or ammonia TS, until the pH is about 3.5, determined potentiometrically, then dilute with water to 40 mL, and mix. Transfer the remaining 35 mL of the solution from (a) to a color-comparison tube closely matching that used for the control, and add diluted acetic acid, or ammonia TS, until the pH is about 3.5, determined potentiometrically, then dilute with water to 40 mL, and mix. Then to each

tube add 10 mL of hydrogen sulfide TS, mix, and compare the colors by viewing through the color-comparison tube downward against a white surface. The color in the test specimen is not darker than that of the control.

If the solution of the reagent is prepared as in (b), use for the control 10 mL of the solution, and add to it a volume of *Standard Lead Solution* equivalent to the amount of lead permitted in 2 g of the reagent. Dilute the remaining 30 mL of solution (b) with water to 35 mL, and proceed as directed in the preceding paragraph, beginning with "add diluted acetic acid, or ammonia TS," in the second sentence.

If the reagent to be tested for heavy metals is a salt of an aliphatic organic acid, substitute 1 N hydrochloric acid for the diluted acetic acid specified in the foregoing method.

Insoluble Matter in Reagents

Dissolve the quantity of reagent specified in the test in 100 mL of water, heat to boiling unless otherwise directed, in a covered beaker, and warm on a steam bath for 1 hour. Filter the hot solution through a tared sintered-glass crucible of fine porosity. Wash the beaker and the filter thoroughly with hot water, dry at 105°, cool in a desiccator, and weigh.

Loss on Drying for Reagents

Determine as directed under *Loss on Drying* (731).

Nitrate in Reagents

STANDARD NITRATE SOLUTION—Dissolve 163 mg of potassium nitrate in water, add water to make 100 mL, and dilute 10 mL of this solution with water to 1 liter, to obtain a solution containing the equivalent of 0.01 mg of NO₃ per mL.

BRUCINE SULFATE SOLUTION—Dissolve 600 mg of brucine sulfate in 600 mL of nitrate-free, dilute sulfuric acid (2 in 3) that previously has been cooled to room temperature, and dilute with the acid to 1 L. [NOTE—Prepare the nitrate-free sulfuric acid by adding 4 parts of sulfuric acid to 1 part of water, heating the solution to dense fumes of sulfur trioxide, and cooling. Repeat the dilution and heating three or four times.]

SAMPLE SOLUTION—To the weight of sample specified in the individual reagent specification, dissolved in the designated volume of water, add *Brucine Sulfate Solution* to make 50 mL.

CONTROL SOLUTION—To a volume of *Standard Nitrate Solution* equivalent to the weight of nitrate (NO₃) specified in the individual reagent specification, add the weight of sample specified in the individual reagent specification and then add *Brucine Sulfate Solution* to make 50 mL.

BLANK SOLUTION—Use 50 mL of *Brucine Sulfate Solution*.

PROCEDURE—Heat the *Sample Solution*, *Control Solution*, and *Blank Solution* in a boiling water bath for 10 minutes, then cool rapidly in an ice bath to room temperature. Adjust a suitable spectrophotometer to zero absorbance at 410 nm with the *Blank Solution*. Determine the absorbance of the *Sample Solution*, note the result, and adjust the instrument to zero absorbance with the *Sample Solution*. Determine the absorbance of the *Control Solution*: the absorbance reading for the *Sample Solution* does not exceed that for the *Control Solution*.

Nitrogen Compounds in Reagents

PROCEDURE—Unless otherwise directed, test for nitrogen compounds as follows: Dissolve the specified quantity of test specimen in 60 mL of ammonia-free water in a Kjeldahl flask

connected through a spray trap to a condenser, the end of which dips below the surface of 10 mL of 0.1 N hydrochloric acid. Add 10 mL of freshly boiled sodium hydroxide solution (1 in 10) and 500 mg of aluminum wire, in small pieces, to the Kjeldahl flask, and allow to stand for 1 hour, protected from loss of, and exposure to, ammonia. Distill 35 mL, and dilute the distillate with water to 50 mL. Add 2 mL of freshly boiled sodium hydroxide solution (1 in 10), mix, add 2 mL of alkaline mercuric-potassium iodide TS, and again mix: the color produced is not darker than that of a control containing the amount of added N (as ammonium chloride) specified in the individual test procedure.

Phosphate in Reagents

STANDARD PHOSPHATE SOLUTION—Dissolve 143.3 mg of dried monobasic potassium phosphate, KH_2PO_4 , in water to make 1000.0 mL. This solution contains the equivalent of 0.10 mg of phosphate (PO_4) in each mL.

PHOSPHATE REAGENT A—Dissolve 5 g of ammonium molybdate in 1 N sulfuric acid to make 100 mL.

PHOSPHATE REAGENT B—Dissolve 200 mg of *p*-methylaminophenol sulfate in 100 mL of water, and add 20 g of sodium bisulfite. Store this reagent in well-filled, tightly stoppered bottles, and use within one month.

PROCEDURE—[NOTE—The tests with the specimen and the control are made preferably in matched color-comparison tubes.] Dissolve the quantity of the reagent specified in the test, or the residue obtained after the prescribed treatment, in 20 mL of water, by warming, if necessary, add 2.5 mL of dilute sulfuric acid (1 in 7), and dilute with water to 25 mL. (If preferable, the test specimen or the residue may be dissolved in 25 mL of approximately 0.5 N sulfuric acid.) Then add 1 mL each of *Phosphate Reagents A* and *B*, mix, and allow to stand at room temperature for 2 hours. Compare any blue color produced with that produced in a control made with the same quantities of the same reagents as in the test with the specimen, and a volume of *Standard Phosphate Solution* equivalent to the quantity of phosphate (PO_4) designated in the reagent specifications.

Residue on Ignition in Reagents

PROCEDURE—Unless otherwise directed, determine the residue on ignition as follows: Weigh accurately 1 to 2 g of the substance to be tested in a suitable crucible that previously has been ignited, cooled, and weighed. Ignite the substance, gently and slowly at first and then at a more rapid rate, until it is thoroughly charred, if organic in nature, or until it is completely volatilized, if inorganic in nature. If the use of sulfuric acid is specified, cool the crucible, add the specified amount of acid, and ignite the crucible gently until fumes no longer are evolved. Then ignite the crucible at $800 \pm 25^\circ$, cool in a suitable desiccator, and weigh. If the use of sulfuric acid is not specified, the crucible need not be cooled but can be ignited directly at $800 \pm 25^\circ$ once the charring or volatilization is complete. Continue the ignition until constant weight is attained, unless otherwise specified.

Conduct the ignition in a well-ventilated hood, but protected from air currents, and at as low a temperature as is possible to effect the complete combustion of the carbon. A muffle furnace may be used, if desired, and its use is recommended for the final ignition at $800 \pm 25^\circ$.

Sulfate in Reagents

STANDARD SULFATE SOLUTION—Dissolve 181.4 mg of potassium sulfate (dried at 105° for 2 hours) in water to make 1000 mL. This solution contains the equivalent of 0.10 mg of sulfate (SO_4) per mL.

PROCEDURE—

Method I—Neutralize, if necessary, a solution of the quantity of the reagent or residue indicated in the test in 25 mL of water, or a solution prepared as directed in the test, with hydrochloric acid or with ammonia TS, litmus paper being used as the indicator, and add 1 mL of 1 N hydrochloric acid. Filter the solution, if necessary, through a filter paper previously washed with water, and add 2 mL of barium chloride TS. Mix, allow to stand for 10 minutes, and compare the turbidity, if any, with that produced in a control containing the same quantities of the same reagents used in the test and a quantity of *Standard Sulfate Solution* equivalent to the quantity of sulfate (SO_4) permitted in the test. Adjust the two solutions with water to the same volume before adding the barium chloride TS.

Method II—Heat to boiling the solution, prepared as directed in the individual test procedure, or the filtrate designated in the procedure, and add 5 mL of barium chloride TS. Then digest the solution on a steam bath for 2 hours, and allow to stand overnight. If any precipitate is formed, filter the solution through paper, wash the residue with hot water, and transfer the paper containing the residue to a tared crucible. Char the paper, without burning, and ignite the crucible and its contents to constant weight. Perform a blank determination concurrently with the test specimen determination, and subtract the weight of residue obtained from that obtained in the test specimen determination to obtain the weight of residue attributable to the sulfate content of the specimen.

REAGENT SPECIFICATIONS

Absolute Ether—See *Ethyl Ether, Anhydrous*.

Absorbent Cotton—Use *Purified Cotton* (USP monograph).

Acetal, $\text{C}_6\text{H}_{14}\text{O}_2$ —**118.2**—Use a suitable grade.

Acetaldehyde (*Ethanal*; *Acetic Aldehyde*), CH_3CHO —**44.05** [75-07-0]—Colorless liquid. Miscible with water and with alcohol. Use ACS reagent grade.

Acetanilide (*Phenylacetamide*; *Antifebrin*), $\text{C}_8\text{H}_9\text{NO}$ —**135.16** [103-84-4]—White, shiny crystals, usually in scales, or a white, crystalline powder. Is stable in air. Freely soluble in alcohol and in chloroform; soluble in boiling water, in ether, and in glycerin; slightly soluble in water.

Melting range (741°): between 114° and 116° .

Reaction—Its saturated solution is neutral to litmus.

Loss on drying (731°)—Dry it over sulfuric acid for 2 hours: it loses not more than 0.5% of its weight.

Residue on ignition (Reagent test): not more than 0.05%.

Acetic Acid (*6 N Acetic Acid*)—Use *Acetic Acid* (NF monograph) or prepare a suitable dilution of glacial acetic acid in such a way as to obtain a final concentration of acetic acid between 36.0% and 37.0%, by weight.

Acetic Acid, Diluted (*1 N Acetic Acid*)—Dilute 60.0 mL of glacial acetic acid with water to make 1000 mL.

Residue on evaporation—Evaporate 50 mL on a steam bath, and dry the residue at 105° for 2 hours: the residue weighs not more than 1 mg (0.002%).

Chloride (Reagent test)—Five mL shows not more than 0.01 mg of Cl (2 ppm).

Sulfate (Reagent test, *Method I*)—Ten mL shows not more than 0.5 mg of SO_4 (50 ppm).

Heavy metals (Reagent test)—Evaporate 20 mL on a steam bath to dryness. Add to the residue 2 mL of the acid, dilute with water to 25 mL, and add 10 mL of hydrogen sulfide TS: any brown color produced is not darker than that

of a control containing 0.04 mg of added Pb and 2 mL of the diluted acetic acid (2 ppm).

Acetic Acid, Glacial, CH_3COOH —**60.05** [64-19-7]—Use ACS reagent grade.

Acetic Anhydride (*Acetic Oxide; Acetyl Oxide*), $(\text{CH}_3\text{CO})_2\text{O}$ —**102.09** [108-24-7]—Use ACS reagent grade.

Acetone (*Propanone; Dimethylformaldehyde*), CH_3COCH_3 —**58.08** [67-64-1]—Use ACS reagent grade. [NOTE—For UV spectrophotometric determinations, use ACS reagent grade Acetone Suitable for Use in UV Spectrophotometry.]

Acetone, Anhydrous, CH_3COCH_3 —**58.08**—Use ACS reagent grade Acetone.

Acetone, Neutralized—To a suitable quantity of acetone add 2 or 3 drops of phenolphthalein TS and a sufficient amount of 0.02 or 0.01 N sodium hydroxide to produce a faint pink color. Prepare neutralized acetone just prior to use.

Acetonitrile (*Methyl Cyanide; Cyanomethane*), CH_3CN —**41.05** [75-05-8]—Use ACS reagent grade.

Acetonitrile, Spectrophotometric—Use ACS reagent grade, which meets also the requirements of the following test.

Spectral purity—Measure in a 1-cm cell between 250 nm and 280 nm, with a suitable spectrophotometer, against air as the blank: its absorbance is not more than 0.01.

Acetophenone (*Phenylethanone; Phenyl Methyl Ketone*), $\text{CH}_3\text{COC}_6\text{H}_5$ —**120.15** [98-86-2]—Liquid. Slightly soluble in water, freely soluble in alcohol and in ether.

Melting range (741): between 19° and 20°.

Refractive index (831): about 1.534 at 20°.

Specific gravity (841): about 1.03.

p-Acetotoluidide, $\text{C}_9\text{H}_{11}\text{NO}$ —**149.19** [103-89-9]—White to off-white powder.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μm layer of phase G2; the injection port temperature is maintained at 230°; the detector temperature is maintained at 300°; and the column temperature is maintained at 130° and programmed to rise 10° per minute to 280°. The area of the $\text{C}_9\text{H}_{11}\text{NO}$ peak is not less than 98.5% of the total peak area.

Melting range (741): between 145° and 151°.

Acetylacetone (*2,4-Pentanedione; Diacetyl methane*), $\text{C}_5\text{H}_8\text{O}_2$ —**100.12** [123-54-6]—Clear, colorless to slightly yellow, flammable liquid. Soluble in water; miscible with alcohol, with chloroform, with acetone, with ether, and with glacial acetic acid.

Assay—Not less than 98% of $\text{C}_5\text{H}_8\text{O}_2$, a suitable gas chromatograph equipped with a flame-ionization detector being used and helium being used as the carrier gas. The following conditions have been found suitable: a 3-mm \times 1.83-m stainless steel column containing 10% phase G43 on support S1A; the injection port and detector temperatures are maintained at 250° and 310°, respectively; the column temperature is programmed to rise 8° per minute, from 50° to 220°.

Refractive index (831): between 1.4505 and 1.4525, at 20°.

Acetyl Chloride, CH_3COCl —**78.50** [75-36-5]—Clear, colorless liquid. Is decomposed by water and by alcohol. Miscible with benzene and with chloroform. Use ACS reagent grade.

Specific gravity (841): about 1.1.

Acetylcholine Chloride (*Trimethylethanaminium Chloride; Acecoline*), $[\text{CH}_3\text{COOCH}_2\text{CH}_2\text{N}(\text{CH}_3)_3]\text{Cl}$ —**181.66** [60-31-1]—White, crystalline powder. Very deliquescent; very soluble in water; freely soluble in alcohol.

Melting range (741)—When previously dried at 110° in a capillary tube for 1 hour, it melts between 149° and 152°.

Reaction—A solution (1 in 10) is neutral to litmus.

Residue on ignition (Reagent test): negligible, from 200 mg.

Solubility in alcohol—A solution of 500 mg in 5 mL of alcohol is complete and colorless.

Percent of acetyl (CH_3CO)—Weigh accurately about 400 mg, previously dried at 105° for 3 hours, and dissolve in 15 mL of water in a glass-stoppered conical flask. Add 40.0 mL of 0.1 N sodium hydroxide VS, and heat on a steam bath for 30 minutes. Insert the stopper, allow to cool, add phenolphthalein TS, and titrate the excess alkali with 0.1 N sulfuric acid VS. Determine the exact normality of the 0.1 N sodium hydroxide by titrating 40.0 mL after it has been treated in the same manner as in the test. Each mL of 0.1 N sodium hydroxide is equivalent to 4.305 mg of CH_3CO . Between 23.2% and 24.2% is found.

Percent of chlorine (Cl)—Weigh accurately about 400 mg, previously dried at 105° for 3 hours, and dissolve in 50 mL of water in a glass-stoppered, 125-mL flask. Add with agitation 30.0 mL of 0.1 N silver nitrate VS, then add 5 mL of nitric acid and 5 mL of nitrobenzene, shake, add 2 mL of ferric ammonium sulfate TS, and titrate the excess silver nitrate with 0.1 N ammonium thiocyanate VS: each mL of 0.1 N silver nitrate is equivalent to 3.545 mg of Cl. Between 19.3% and 19.8% of Cl is found.

3-Acetylthio-2-methylpropanoic Acid, $\text{C}_6\text{H}_{10}\text{O}_3\text{S}$ —**162.21**—Use a suitable grade.

[NOTE—A suitable grade is available as β -(Acetylmercapto)isobutyric Acid, catalog number 39059, from Senn Chemicals AG www.sennchem.com.]

N-Acetyl-L-tyrosine Ethyl Ester, $\text{C}_{13}\text{H}_{17}\text{NO}_4$ —**251.28**—Determine the suitability of the material as directed in the *Assay* under *Chymotrypsin* (USP monograph).

Acrylic Acid (*2-Propenoic Acid; Vinylformic Acid*), $\text{C}_3\text{H}_4\text{O}_2$ —**72.06** [79-10-7]—Colorless liquid. Miscible with water, with alcohol, and with ether.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)), equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μm layer of phase G2; the injection port temperature is maintained at 150°; the detector temperature is maintained at 300°; and the column temperature is maintained at 50° and programmed to rise 10° per minute to 200°. The area of the $\text{C}_3\text{H}_4\text{O}_2$ peak is not less than 99% of the total peak area.

Refractive index (831): between 1.419° and 1.423° at 20°.

Activated Alumina—See *Alumina, Activated*.

Activated Charcoal—See *Charcoal, Activated*.

Activated Magnesium Silicate—See *Magnesium Silicate, Activated*.

Adamantane, $\text{C}_{10}\text{H}_{16}$ —**136.23** [281-23-2]

Melting range (741): between 270° and 271°.

Adenine Sulfate, $(\text{C}_5\text{H}_5\text{N}_5)_2 \cdot \text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ —**404.36**—White crystals or crystalline powder. Melts, after drying at 110°, at about 200° with some decomposition. One g dissolves in about 160 mL of water; less soluble in alcohol. Soluble in solutions of sodium hydroxide. It is not precipitated from solution by iodine TS or mercuric-potassium iodide TS, but a precipitate is produced with trinitrophenol TS.

Residue on ignition (Reagent test): negligible, from 100 mg.

Water—Dry it at 105° to constant weight: it loses not more than 10.0% of its weight.

Adipic Acid (*Hexanedioic Acid; 1,4-Butanedicarboxylic Acid*), $\text{C}_6\text{H}_{10}\text{O}_4$ —**146.14** [124-04-9]—Colorless to white, crystalline powder. Slightly soluble in water and in cyclohexane; soluble in alcohol, in methanol, and in acetone; practically insoluble in benzene and in petroleum benzin.

Assay—Weigh accurately about 0.3 g, and dissolve in 50 mL of alcohol. Add 25 mL of water, mix, and titrate with 0.5 N sodium hydroxide VS to a pH of 9.5. Perform a blank determination, and make any necessary correction. Each mL of 0.5 N sodium hydroxide is equivalent to 36.54 mg of $C_6H_{10}O_4$. Not less than 98% is found.

Melting range (741): between 151° and 155°, but the range between beginning and end of melting does not exceed 2°.

Agar—Use *Agar* (NF monograph). When used for bacteriological purposes, it is to be dried to a water content of not more than 20%.

Agarose [9012-36-6]—Polysaccharide consisting of 1,3-linked β -D-galactopyranose and 1,4-linked 3,6-anhydro- α -L-galactopyranose. Use a suitable grade.

Air-Helium Certified Standard—A mixture of 1.0% air in industrial grade helium. It is available from most suppliers of specialty gases.

Albumin Bovine Serum [9048-46-8]—Almost colorless to faintly yellow powder. Not less than 95% pure. Solubility, 40 mg in 1 mL of water. Molecular weight is approximately 66,000. Use a suitable grade. Store between 2° and 8°.

Alcohol, Ethanol, Ethyl Alcohol, C_2H_5OH —46.07 [64-17-5]—Use a suitable grade with a content of NLT 92.3% and NMT 93.8%, by weight, corresponding to NLT 94.9% and NMT 96% by volume, at 15.56°.

Alcohol, 70 Percent, 80 Percent, and 90 Percent—Prepare by mixing alcohol and water in the proportions given, the measurements being made at 25°.

Percent by Volume of C_2H_5OH at 15.56°	Specific Gravity at 25°	Relative Proportions		Volume in mL of Alcohol, 94.9% v/v, Required for 100 mL
		Alcohol, mL	Water, mL	
70	0.884	38.6	15	73.7
80	0.857	45.5	9.5	84.3
90	0.827	51	3	94.8

The proportions of alcohol and water taken to prepare these or any other percentage (v/v) solutions may be determined as follows. Calculate the amount, in mL, of water to be mixed with 100 mL of alcohol taken by the formula:

$$[94.9(d/c) - 0.8096]100$$

in which 94.9 is the percentage (v/v) of C_2H_5OH in alcohol, 0.8096 is the specific gravity of 94.9% alcohol, d is the specific gravity, obtained from the Alcoholometric Table (see *Reference Tables*), of the solution containing $c\%$ (v/v) of C_2H_5OH , and 100 is the volume, in mL, of alcohol taken.

Alcohol, Absolute, C_2H_5OH —46.07—Use ACS reagent grade Ethyl Alcohol, Absolute.

Alcohol, Aldehyde-free—Dissolve 2.5 g of lead acetate in 5 mL of water, add the solution to 1000 mL of alcohol contained in a glass-stoppered bottle, and mix. Dissolve 5 g of potassium hydroxide in 25 mL of warm alcohol, cool the solution, and add it slowly, without stirring, to the alcohol solution of lead acetate. After 1 hour shake the mixture vigorously, allow it to stand overnight, decant the clear liquid, and recover the alcohol by distillation.

Alcohol, Amyl—See *Amyl Alcohol*.

Alcohol, Dehydrated (Absolute Alcohol), C_2H_5OH —46.07—Use ACS reagent grade Ethyl Alcohol, Absolute.

Alcohol, Dehydrated Isopropyl—See *Isopropyl Alcohol, Dehydrated*.

Alcohol, Denaturated—It is ethyl alcohol to which has been added some substance or substances which, while allowing the use of the alcohol in most applications, renders it entirely unfit for consumption as a beverage. The most common denaturants used, either alone or in combination, are the following: methanol, camphor, aldehyd, amyl alco-

hol, gasoline, isopropanol, terpineol, benzene, castor oil, acetone, nicotine, aniline dyes, ether, cadmium iodide, pyridine bases, sulfuric acid, kerosene, and diethyl phthalate. Use a suitable grade.

Alcohol, Diluted—Use *Diluted Alcohol* (NF monograph).

Alcohol, Isobutyl—See *Isobutyl Alcohol*.

Alcohol, Isopropyl—See *Isopropyl Alcohol*.

Alcohol, Methyl—See *Methanol*.

Alcohol, Neutralized—To a suitable quantity of alcohol add 2 or 3 drops of phenolphthalein TS and just sufficient 0.02 N or 0.1 N sodium hydroxide to produce a faint pink color. Prepare neutralized alcohol just prior to use.

Alcohol, n -Propyl—See *n-Propyl Alcohol*.

Alcohol, Secondary Butyl—See *Butyl Alcohol, Secondary*.

Alcohol, Tertiary Butyl—See *Butyl Alcohol, Tertiary*.

Aldehyde Dehydrogenase—A white powder. One mg contains not less than 2 enzyme activity units.

Assay—Transfer about 20 mg, accurately weighed, to a 200-mL volumetric flask, dissolve in 1 mL of water, dilute with an ice-cold solution of bovine serum albumin (1 in 100) to volume, and mix. Use this solution as the *Assay preparation*. Dissolve 3.3 g of potassium pyrophosphate, 15 mg of dithiothreitol, and 40 mg of edetate disodium in 70 mL of water, adjust with citric acid monohydrate solution (2.1 in 10) to a pH of 9.0 ± 0.1 , dilute with water to 100 mL, and mix to obtain a pH 9.0 buffer. Dissolve an accurately weighed quantity of β -nicotinamide adenine dinucleotide (β -NAD) in water to obtain a β -NAD solution having a known concentration of about 20 mg per mL. Pipet 0.1 mL of the *Assay preparation* into a 1-cm spectrophotometric cell. Pipet 0.1 mL of water into a second 1-cm spectrophotometric cell to provide the reagent blank. Add 2.5 mL of pH 9.0 buffer, 0.2 mL of β -NAD solution, and 0.1 mL of pyrazole solution (0.68 in 100) to each cell, and mix. Stopper the cells, and allow to stand for 2 minutes at $25 \pm 1^\circ$. Add 0.01 mL of acetaldehyde solution (0.3 in 100) to each cell, and mix. Stopper the cells, and determine the absorbance of the solution obtained from the *Assay preparation* at a wavelength of 340 nm, using the solution obtained from the reagent blank as the reference. Calculate the change, ΔA , in absorbance per minute for the solution obtained from the *Assay preparation*, starting at the point when the absorbance and time relationship becomes linear. One enzyme activity unit is defined as the amount of enzyme that oxidizes 1 μ mol of acetaldehyde per minute when the test is conducted under the conditions described herein. Calculate the enzyme activity units in each mg of aldehyde dehydrogenase taken by the formula:

$$[(2.91)(200)/(6.3)(0.1)(1000)](\Delta A/W)$$

in which ΔA is as defined above and W is the weight, in g, of aldehyde dehydrogenase taken.

Alkaline Phosphatase Enzyme—See *Phosphatase Enzyme, Alkaline*.

Alkylphenoxypolyethoxyethanol—A nonionic surfactant. Use a suitable grade.

[NOTE—A suitable grade is available commercially as "Triton X-100" from Sigma-Aldrich, www.sigma-aldrich.com.]

Alpha-Chymotrypsin—25 kDa [9004-07-3]—Use a suitable salt-free grade for protein sequencing.

[NOTE—A suitable grade is available as catalog number 4423 from www.sigma-aldrich.com.]

Alpha-Cyclodextrin Hydrate (Alpha-Schardinger Dextrin; Cyclohexaamylose), $C_{36}H_{60}O_{30} \cdot xH_2O$ [51211-51-9]—Use a suitable grade with a content of NLT 98%.

[NOTE—A suitable grade is available as catalog number 22729 from www.acros.com.]

Alpha-(2-(methylamino)ethyl)benzyl alcohol—Use a suitable grade.

Alphanaphthol—See *1-Naphthol*.

Alprenolol Hydrochloride, $C_{15}H_{23}NO_2 \cdot HCl$ —285.8 [13707-88-5]—Use a suitable grade.

Alum (Ammonium Alum, Aluminum Ammonium Sulfate), $AlNH_4(SO_4)_2 \cdot 12H_2O$ —453.33 [7784-26-1]—Large, color-

less crystals or crystalline fragments or a white powder. Soluble in 7 parts of water and in about 0.5 part of boiling water; insoluble in alcohol. Use ACS reagent grade.

Ammonium Alum—See *Alum*.

Alumina—See *Aluminum Oxide, Acid-washed*.

Alumina, Activated (*Aluminum Oxide*), [1344-28-1]—Use a suitable grade.

Alumina, Anhydrous (*Aluminum Oxide; Alumina specially prepared for use in chromatographic analysis*) [1344-28-1]—A white or practically white powder, 80- to 200-mesh. It does not soften, swell, or decompose in water. It is not acid-washed. Store it in well-closed containers.

Aluminon (*Aurin Tricarboxylic Acid, [tri]Ammonium Salt*), $C_{22}H_{23}N_3O_9$ —**473.43** [569-58-4]—Yellowish-brown, glassy powder. Freely soluble in water. Use ACS reagent grade.

Aluminum, Al—At. Wt. 26.98154 [7429-90-5]—Use ACS reagent grade, which also meets the requirements of the following test.

Arsenic—Place 750 mg in a generator bottle (see *Arsenic in Reagents under General Tests for Reagents*), omitting the pledget of cotton. Add 10 mL of water and 10 mL of sodium hydroxide solution (3 in 10), and allow the reaction to proceed for 30 minutes: not more than a barely perceptible stain is produced on the mercuric bromide test paper.

Aluminum Oxide, Acid-Washed (*Alumina specially prepared for use in chromatographic analysis*) [1344-28-1]—White or practically white powder or fine granules. Very hygroscopic. Store in tight containers.

pH of Slurry—The pH of a well-mixed slurry of 5 g in 150 mL of ammonia-free and carbon dioxide-free water, after 10 minutes' standing, is between 3.5 and 4.5.

Loss on ignition—Weigh accurately about 1 g, and ignite, preferably in a muffle furnace at 800° to 825°, to constant weight: it loses not more than 5.0% of its weight.

Silica—Fuse 500 mg with 10 g of potassium bisulfate for 1 hour in a platinum crucible, cool, and dissolve in hot water: not more than a small amount of insoluble matter remains.

Suitability for chromatographic adsorption—Dissolve 50 mg of o-nitroaniline in benzene to make 50.0 mL. Dilute 10 mL of the resulting solution with benzene to 100.0 mL, and mix (*Solution A*).

Weigh quickly about 2 (± 0.005) g of specimen in a glass-stoppered weighing bottle, and rapidly transfer it to a dry, glass-stoppered test tube. Add 20.0 mL of *Solution A*, insert the stopper, shake vigorously for 3 minutes, and allow to settle.

Pipet 10 mL of the clear supernatant into a 100-mL volumetric flask, dilute with benzene to volume, and mix (*Solution B*).

Determine the absorbances of *Solutions A* and *B* at 395 nm, with a suitable spectrophotometer, using benzene as the blank. Calculate the quantity, in mg, adsorbed per g of test specimen by the formula:

$$[2(1 - A_B/A_A)]/W$$

in which A_A and A_B are the absorbances of *Solutions A* and *B*, respectively; and W is the weight, in g, of the aluminum oxide. Not less than 0.3 mg of o-nitroaniline is adsorbed for each g of the aluminum oxide.

Aluminum Potassium Sulfate, $AlK(SO_4)_2 \cdot 12H_2O$ —**474.39** [10042-67-1]—Use ACS reagent grade.

Amaranth, $C_{20}H_{11}N_2Na_3O_{10}S_3$ —**604.48** [915-67-3]—A deep brown or dark reddish-brown fine powder. Use a suitable grade.

Aminoacetic Acid (*Glycine*), NH_2CH_2COOH —**75.07**

[56-40-6]—White, crystalline powder. Very soluble in water; slightly soluble in alcohol.

Nitrogen content (Reagent test)—Determine by the Kjeldahl method, using a test specimen previously dried at 105° for 2 hours: between 18.4% and 18.8% of N is found, corresponding to not less than 98.5% of $C_2H_5NO_2$.

Insoluble matter (Reagent test): not more than 1 mg, from 10 g (0.01%).

Residue on ignition (Reagent test): not more than 0.05%.

Chloride (Reagent test)—One g shows not more than 0.1 mg of Cl (0.01%).

Sulfate (Reagent test, *Method I*)—Two g shows not more than 0.1 mg of SO_4 (0.005%).

Heavy metals (Reagent test): 0.001%, 5 mL of 1 N hydrochloric acid VS being used to acidify the solution of the test specimen.

Iron (241)—One g, dissolved in 47 mL of water containing 3 mL of hydrochloric acid, shows not more than 0.01 mg of Fe (0.001%).

4-Aminoantipyrine, $C_{11}H_{13}N_3O$ —**203.24** [83-07-8]—Light yellow, crystalline powder. A 500-mg portion dissolves completely in 30 mL of water and yields a clear solution.

Melting range (741): between 108° and 110°.

p-Aminobenzoic Acid—See *Para-aminobenzoic Acid*.

2-Aminobenzonitrile (*Anthranilonitrile*), $C_7H_6N_2$ —**118.14** [1885-29-6]—Use 2-Aminobenzonitrile 98%.

Melting range (741): between 49° and 52°.

4-Amino-6-chloro-1,3-benzenedisulfonamide, $C_6H_8ClN_3O_4S_2$ —**285.73** [121-30-2]—White powder. Insoluble in water and in chloroform; soluble in ammonia TS.

Residue on ignition (Reagent test): not more than 2 mg from 2 g (0.1%).

Absorbance—A 1 in 200,000 solution in methanol exhibits absorbance maxima at about 223 nm, 265 nm, and 312 nm. Its absorptivity (see *Spectrophotometry and Light-Scattering* (851)) at 265 nm is about 64.0.

4-Amino-2-chlorobenzoic Acid, $C_6H_3Cl(NH_2)(COOH)$ —**171.58** [2457-76-3]—White crystals or white, crystalline powder.

Melting range (741): between 208° and 212°.

2-Amino-5-chlorobenzophenone, $C_{13}H_9ClNO$ —**231.68** [719-59-5]—Use USP 2-Amino-5-chlorobenzophenone RS.

7-Aminodesacetoxycephalosporanic Acid, $C_8H_{10}N_2O_3S$ —**214.2**—Light yellow powder.

Ordinary impurities (466)—

Test solution: 1 N ammonium hydroxide.

Standard solution: 1 N ammonium hydroxide.

Eluant: 0.5 N sodium chloride.

Visualization: 1.

2-Aminoethyl Diphenylborinate—See *Diphenylborinic Acid, Ethanolamine Ester*.

1-(2-Aminoethyl)piperazine, $C_6H_{15}N_3$ —**129.20** [140-31-8]—Viscous, colorless liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with G2. The injection port temperature is maintained at 280°; the column temperature is maintained at 180° and programmed to rise 10° per minute to 280° and held there for 10 minutes. The detector temperature is maintained at 300°. The area of the main peak is not less than 97% of the total peak area.

Refractive index (831): between 1.4978 and 1.5010 at 20°.

Aminoguanidine Bicarboxylate (*Aminoguanidine Hydrogen Carbonate*), $\text{CH}_6\text{N}_4 \cdot \text{H}_2\text{CO}_3$ —**136.11** [2582-30-1]—White powder.

Assay—Dissolve about 34 mg, accurately weighed, in 50 mL of glacial acetic acid. Titrate with 0.1 N perchloric acid VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary corrections. Each mL of 0.1 N perchloric acid is equivalent to 13.61 mg of $\text{CH}_6\text{N}_4 \cdot \text{H}_2\text{CO}_3$. Not less than 98.5% is found.

Melting point (741): about 170°, with decomposition.

2-Aminoheptane (*2-Heptylamine*; *1-Methylhexylamine*), $\text{C}_7\text{H}_{17}\text{N}$ —**115.22** [123-82-0]—Use a suitable grade with a content of not less than 99%.

N-Aminohexamethyleneimine (*N-Aminohomopiperidine*, *1-Aminohomopiperidine*), $\text{C}_6\text{H}_{14}\text{N}_2$ —**114.19** [5906-35-4]—Colorless liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with G2. The injection port temperature is maintained at 180°; the column temperature is maintained at 80° and programmed to rise 10° per minute to 230° and then maintained at 230° for 5 minutes. The detector temperature is maintained at 300°. The area of the main peak is not less than 95% of the total peak area.

Refractive index (831): between 1.4840 and 1.4860 at 20°.

4-Amino-3-hydroxy-1-naphthalenesulfonic Acid, $\text{C}_{10}\text{H}_9\text{NO}_4\text{S}$ —**239.25** [116-63-2]—Light purple powder. Use ACS reagent grade.

8-Amino-6-methoxyquinoline (*6-Methoxy-8-aminoquinoline*), $\text{C}_{10}\text{H}_{10}\text{N}_2\text{O}$ —**174.2** [90-52-8]—Use a suitable grade with a content of not less than 98.0%.

[NOTE—A suitable grade is available from www.3bmedical.com, catalog number 3B3-002598.]

1,2,4-Aminonaphtholsulfonic Acid, $\text{C}_{10}\text{H}_9\text{NO}_4\text{S}$ —**239.25**—White to slightly brownish pink powder. Sparingly soluble in water.

Sensitivity—Dissolve 100 mg in 50 mL of freshly prepared sodium bisulfite solution (1 in 5), warming if necessary to effect solution, and filter. Add 1 mL of the filtrate to a solution prepared by adding 2 mL of dilute sulfuric acid (1 in 6) and 1 mL of *Phosphate Reagent A* (see *Reagent test*) to 20 mL of a 1 in 100 dilution of *Standard Phosphate Solution* (see *Reagent test*): a distinct blue color develops within 5 minutes.

Solubility in sodium carbonate solution—Dissolve 100 mg in 3 mL of sodium carbonate TS, and add 17 mL of water: not more than a trace remains undissolved.

Residue on ignition (*Reagent test*)—To 1 g add 0.5 mL of sulfuric acid, and ignite at 800 \pm 25° to constant weight: the residue weighs not more than 5 mg (0.5%).

Sulfate (*Reagent test, Method I*)—Heat 500 mg with a mixture of 25 mL of water and 2 drops of hydrochloric acid on a steam bath for 10 minutes. Cool, dilute with water to 200 mL, and filter: 20 mL of the filtrate shows not more than 0.25 mg of SO_4 (0.5%).

2-Aminophenol (*o-Aminophenol*; *2-Hydroxyaniline*), $\text{C}_6\text{H}_7\text{NO}$ —**109.13** [95-55-6]—Off-white powder. Use a suitable grade with a content of not less than 99%.

m-Aminophenol (*3-Amino-1-Hydroxybenzene*), $\text{C}_6\text{H}_7\text{NO}$ —**109.13** [591-27-5]—Cream-colored to pale yellow flakes.

Sparingly soluble in cold water; freely soluble in hot water, in alcohol, and in ether.

Assay—Dissolve about 1.5 g, accurately weighed, in about 400 mL of water in a 500-mL volumetric flask, dilute with water to volume, and mix. Transfer 25.0 mL of this solution to an iodine flask, add 50.0 mL of 0.1 N bromine VS, dilute with 50 mL of water, add 5 mL of hydrochloric acid, and immediately insert the stopper in the flask. Shake for 1 minute, allow to stand for 2 minutes, and add 5 mL of potassium iodide TS through the slightly loosened stopper. Shake thoroughly, allow to stand for 5 minutes, remove the stopper, and rinse it and the neck of the flask with 20 mL of water, adding the rinsing to the flask. Titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. From the volume of 0.1 N sodium thiosulfate used, calculate the volume, in mL, of 0.1 N bromine consumed by the test specimen. Each mL of 0.1 N bromine is equivalent to 1.819 mg of $\text{C}_6\text{H}_7\text{NO}$: not less than 99.5% is found.

Melting range (741): between 121° and 123°.

Loss on drying (731)—Dry it over calcium chloride for 4 hours: the loss in weight is negligible.

Residue on ignition (*Reagent test*): negligible, from 2 g.

p-Aminophenol (*p-Hydroxyaniline*), $\text{C}_6\text{H}_7\text{NO}$ —**109.13** [123-30-8]—Fine, yellowish, crystalline powder. Slightly soluble in water and in alcohol. Use a suitable grade with a content of not less than 99%.

3-Amino-1-propanol, $\text{H}_2\text{N}(\text{CH}_2)_3\text{OH}$ —**75.11** [156-87-6]—Liquid.

Boiling range (*Reagent test*): between 184° and 188°.

Refractive index (831): between 1.461 and 1.463 at 20°.

3-Aminopropionic Acid (β -Alanine), $\text{NH}_2\text{CH}_2\text{CH}_2\text{COOH}$ —**89.09** [107-95-9]—Use a suitable grade.

3-Aminosalicylic Acid, $\text{C}_7\text{H}_7\text{NO}_3$ —**153.14** [570-23-0]—Tan-grey powder. Use a suitable grade with a content of not less than 97%.

Ammonia Detector Tube—A fuse-sealed glass tube so designed that gas may be passed through it and containing suitable absorbing filters and support media for the indicator bromophenol blue.

Measuring range: 5 to 70 ppm.

[NOTE—Available from Draeger Safety, Inc., www.draeger.com, or from Gastec Corp., www.gastec.co.jp, distributed in the USA by www.nextteq.com.]

Ammonia Solution, Diluted—Use *Ammonia TS*.

Ammonia Water, 25 Percent [1336-21-6]—Use a suitable grade.

Ammonia Water, Stronger (*Ammonium Hydroxide*)—[1336-21-6]—Use ACS reagent grade Ammonium Hydroxide.

Ammonium Acetate, $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$ —**77.08** [631-61-8]—Use ACS reagent grade.

Ammonium Bicarbonate (*Ammonium Hydrogen Carbonate*), NH_4HCO_3 —**79.06** [1066-33-7]—Use a suitable grade with a content of NLT 99.0%.

Ammonium Bisulfate (*Ammonium Hydrogen Sulfate*), NH_4HSO_4 —**115.11** [7803-63-6]—White crystals. Freely soluble in water; practically insoluble in alcohol, in acetone, and in pyridine.

Assay—Dissolve about 300 mg, accurately weighed, in 50 mL of a mixture of water and alcohol (25:25). Titrate with 0.1 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination and make any necessary correction. Each mL of 0.1 N sodium hydrox-

ide is equivalent to 11.51 mg of NH_4HSO_4 . Not less than 98% is found.

Ammonium Bromide, NH_4Br —**97.94** [12124-97-9]—Use ACS reagent grade.

Ammonium Carbonate (*Hartshorn Salt*) [506-87-6]—Use ACS reagent grade.

Ammonium Chloride (*Salmiac*), NH_4Cl —**53.49** [12125-02-9]—Use ACS reagent grade.

Ammonium Citrate, Dibasic (*Citric Acid Diammonium Salt*), $(\text{NH}_4)_2\text{HC}_6\text{H}_5\text{O}_7$ —**226.18** [3012-65-5]—Use ACS reagent grade.

Ammonium Dihydrogen Phosphate—See *Ammonium Phosphate, Monobasic*.

Ammonium Fluoride, NH_4F —**37.04** [12125-01-8]—Use ACS reagent grade.

Ammonium Formate (*Formic Acid Ammonium Salt*), CH_3NO_2 —**63.06** [540-69-2]—Use a suitable grade.

Ammonium Hydroxide (*Ammonium Aqueous*), [1336-21-6]—Use ACS reagent grade.

Ammonium Hydroxide, 6 N—Prepare by diluting 400 mL of *Ammonia Water, Stronger* (see *Reagents* section) with water to make 1000 mL.

Ammonium Molybdate, $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$ —**1235.86** [12054-85-2]—Use ACS reagent grade.

Ammonium Nitrate, NH_4NO_3 —**80.04** [6484-52-2]—Use ACS reagent grade.

Ammonium Oxalate, $(\text{NH}_4)_2\text{C}_2\text{O}_4 \cdot \text{H}_2\text{O}$ —**142.11** [6009-70-7]—Use ACS reagent grade.

Ammonium Persulfate (*Ammonium Peroxydisulfate*), $(\text{NH}_4)_2\text{S}_2\text{O}_8$ —**228.20** [7727-54-0]—Use ACS reagent grade Ammonium Peroxydisulfate.

Ammonium Phosphate, Dibasic (*Diammonium Hydrogen Phosphate*), $(\text{NH}_4)_2\text{HPO}_4$ —**132.06** [7783-28-0]—Use ACS reagent grade.

Ammonium Phosphate, Monobasic (*Ammonium Dihydrogen Phosphate*), $\text{NH}_4\text{H}_2\text{PO}_4$ —**115.03** [7722-76-1]—Use ACS reagent grade.

Ammonium Pyrrolidinedithiocarbamate (*1-pyrrolidine-carbodithioic acid, ammonium salt*), $\text{C}_5\text{H}_{12}\text{N}_2\text{S}_2$ —**164.29** [5108-96-3]—Use a suitable grade.

Ammonium Reineckate (*Reinecke Salt*), $\text{NH}_4[\text{Cr}(\text{NH}_3)_2(\text{SCN})_4] \cdot \text{H}_2\text{O}$ —**354.44** [13573-16-5]—Dark red crystals or red, crystalline powder. Moderately soluble in cold water; more soluble in hot water. Gradually decomposes in solution.

Sensitivity—Dissolve 50 mg in 10 mL of water. Add 0.2 mL of the solution to 1 mL of a solution of 10 mg of choline chloride in 20 mL of water, and shake gently: a distinct precipitate forms within 5 to 10 seconds.

Ammonium Sulfamate, $\text{NH}_4\text{OSO}_2\text{NH}_2$ —**114.13** [7773-06-0]—Use ACS reagent grade.

Ammonium Sulfate, $(\text{NH}_4)_2\text{SO}_4$ —**132.14** [7783-20-2]—Use ACS reagent grade.

Ammonium Thiocyanate (*Ammonium Rhodanide*), NH_4SCN —**76.12** [1762-95-4]—Use ACS reagent grade.

Ammonium Vanadate (*Ammonium Metavanadate*), NH_4VO_3 —**116.98** [7803-55-6]—White, crystalline powder. Slightly soluble in cold water; soluble in hot water and in dilute ammonia TS.

Assay—Weigh accurately about 500 mg, transfer to a suitable container, add 30 mL of water and 2 mL of dilute sulfuric acid (1 in 4), swirl to dissolve, and pass sulfur dioxide gas through the solution until reduction is complete and the solution is bright blue in color. Boil gently while passing

a stream of carbon dioxide through the solution to remove any excess sulfur dioxide, then cool, and titrate with 0.1 N potassium permanganate VS. Each mL of 0.1 N potassium permanganate consumed is equivalent to 11.7 mg of NH_4VO_3 . Not less than 98.0% is found.

Solubility in ammonium hydroxide—Dissolve 1 g in a mixture of 3 mL of ammonium hydroxide and 50 mL of warm water: the solution is clear and colorless.

Carbonate—To 500 mg add 1 mL of water and 2 mL of diluted hydrochloric acid: no effervescence is produced.

Chloride—Dissolve 250 mg in 40 mL of hot water, add 2 mL of nitric acid, and allow to stand for 1 hour. Filter, and to the filtrate add 0.5 mL of silver nitrate TS: any turbidity produced does not exceed that of a blank containing 0.5 mg of added Cl (0.2%).

Sulfate—Dissolve 500 mg in 50 mL of hot water, and add 2 mL of diluted hydrochloric acid and 1.5 g of hydroxylamine hydrochloride. Heat at 60° for 3 minutes, filter, cool, and add to the filtrate 2 mL of barium chloride TS: no turbidity or precipitate is produced within 30 minutes.

Amyl Acetate (*Isoamyl Acetate*), $\text{CH}_3\text{CO}_2\text{C}_5\text{H}_{11}$ —**130.18** [2308-18-1]—Clear, colorless liquid. Slightly soluble in water. Miscible with alcohol, with amyl alcohol, with benzene, and with ether.

Specific gravity (841): about 0.87.

Boiling range (Reagent test, *Method I*): not less than 90°, between 137° and 142°.

Solubility in diluted alcohol—A 1.0-mL portion dissolves in 20 mL of diluted alcohol to form a clear solution.

Acidity—Add 5.0 mL to 40 mL of neutralized alcohol, and, if the pink color is discharged, titrate with 0.10 N sodium hydroxide: not more than 0.20 mL is required to restore the pink color (about 0.02% as CH_3COOH).

Water—A 5-mL portion gives a clear solution with 5 mL of carbon disulfide.

Amyl Alcohol (*Isoamyl Alcohol*), $\text{C}_5\text{H}_{11}\text{OH}$ —**88.15** [598-75-4]—Use ACS reagent grade Isopentyl Alcohol.

tert-Amyl Alcohol, $\text{C}_5\text{H}_{12}\text{O}$ —**88.15** [75-85-4]—Clear, colorless, flammable, volatile liquid.

Specific gravity (841): about 0.81.

Boiling range (Reagent test): not less than 95°, between 100° and 103°.

Residue on evaporation—Evaporate 50 mL (40 g) on a steam bath, and dry at 105° for 1 hour: the residue weighs not more than 1.6 mg (0.004%).

Acids and esters—Dilute 20 mL with 20 mL of alcohol, add 5.0 mL of 0.1 N sodium hydroxide VS, and reflux gently for 10 minutes. Cool, add 2 drops of phenolphthalein TS, and titrate the excess sodium hydroxide with 0.1 N hydrochloric acid VS: not more than 0.75 mL of the 0.10 N sodium hydroxide is consumed, correction being made for the amount consumed in a blank (0.06% as amyl acetate).

Aldehydes—Shake 5 mL with 5 mL of potassium hydroxide solution (30 in 100) in a glass-stoppered cylinder for 5 minutes, and allow to separate: no color develops in either layer.

α -Amylase—Use a suitable grade. It can be from vegetal or animal or microbiological origin.

(E)-Anethole (*1-Methoxy-4-(1-propenyl)benzene*), $\text{C}_{10}\text{H}_{12}\text{O}$ —**148.20** [4180-23-8]—Use a suitable grade of transomer.

Anhydrous Alumina—See *Alumina, Anhydrous*.

Anhydrous Barium Chloride—See *Barium Chloride, Anhydrous*.

Anhydrous Calcium Chloride—See *Calcium Chloride, Anhydrous*.

Anhydrous Cupric Sulfate—See *Cupric Sulfate, Anhydrous*.

Anhydrous Dibasic Sodium Phosphate—See *Sodium Phosphate, Dibasic, Anhydrous*.

Anhydrous Magnesium Perchlorate—See *Magnesium Perchlorate, Anhydrous*.

Anhydrous Magnesium Sulfate—See *Magnesium Sulfate, Anhydrous*.

Anhydrous Methanol—See *Methanol, Anhydrous*.

Anhydrous Potassium Carbonate—See *Potassium Carbonate, Anhydrous*.

Anhydrous Sodium Acetate—See *Sodium Acetate, Anhydrous*.

Anhydrous Sodium Carbonate—See *Sodium Carbonate, Anhydrous*.

Anhydrous Sodium Sulfate—See *Sodium Sulfate, Anhydrous*.

Anhydrous Sodium Sulfite—See *Sodium Sulfite, Anhydrous*.

Aniline, $C_6H_5NH_2$ —**93.13** [62-53-3]—Use ACS reagent grade.

Aniline Blue (*Certified Biological Aniline Blue*)

[8004-91-9]—A water-soluble dye consisting of a mixture of the tri-sulfonates of triphenylparosaniline and of diphenylrosaniline.

Aniline Sulfate, $C_{12}H_{14}N_2 \cdot H_2SO_4$ —**284.33** [542-16-5]—Use a suitable grade.

Anion-Exchange Resin, Chloromethylated Polystyrene-Divinylbenzene—Strongly basic, cross-linked resin containing quaternary ammonium groups. It consists of small, moist, yellow beads having a characteristic amine odor. It is available in the chloride form which can be converted to the hydroxide form by regeneration with sodium hydroxide solution (1 in 4). For satisfactory regeneration a contact time of about 25 minutes is required, after which it must be washed with water until neutral. Suitable for use in column chromatography.

[NOTE—A suitable resin is "Amberlite IRA-400," available from Sigma-Aldrich, www.sigma-aldrich.com.]

Anion-Exchange Resin, Strong, Lightly Cross-Linked, in the Chloride Form—Use a suitable grade.

[NOTE—A suitable resin is "AG 1-X4, catalog number 140-1331," produced by BioRad Laboratories, www.bio-rad.com.]

Anion-Exchange Resin, Styrene-Divinylbenzene—Strongly basic, cross-linked resin containing quaternary ammonium groups and about 8% of divinylbenzene. It is available in the chloride form in the 50- to 100-, 100- to 200-, and 200- to 400-mesh sizes. It can be converted to the hydroxide form by regeneration with a sodium hydroxide solution (5 in 100). Insoluble in water, in methanol, and in acetonitrile. Suitable for use in column chromatography.

[NOTE—A suitable resin is Dowex 1X8, produced by Dow Chemical Co. (www.dow.com) and available through Sigma-Aldrich (www.sigma-aldrich.com).]

Anion-Exchange Resin, 50- to 100-Mesh, Styrene-Divinylbenzene—Strongly basic, cross-linked resin containing quaternary ammonium groups and about 4% of divinylbenzene. It consists of tan-colored beads that may be relatively free flowing. It is available in the chloride form which can be converted to the hydroxide form by regeneration with a sodium hydroxide solution (5 in 100). For satisfactory regeneration a contact time of at least 30 minutes is required after which it must be washed free of excess alkali. Insoluble in water, in methanol, and in acetonitrile. Suitable for use in column chromatography.

[NOTE—A suitable resin is "Dowex 1X4," available from Sigma-Aldrich, www.sigma-aldrich.com.]

Moisture content of fully regenerated and expanded resin—Transfer 10 to 12 mL of the resin (as received) to a flask,

and convert it completely to the chloride form by stirring with 150 mL of hydrochloric acid (5 in 100) for not less than 30 minutes. Decant the acid, and wash the resin in the same manner with distilled water until the wash water is neutral to litmus.

Transfer 5 to 7 mL of the regenerated resin to a glass filtering crucible, and remove only the excess surface water by very careful suction filtration. Transfer the conditioned, dried resin to a tared weighing bottle, and weigh. Dry in a vacuum oven at 100° to 105° and at a pressure of 50 mm of mercury for 16 hours. Transfer from the vacuum oven to a desiccator, and cool to room temperature. Reweigh. The loss in weight is between 50% and 65%.

Total new volume capacity—Transfer 2.5 to 3 mL of the conditioned, undried (See *Moisture content*, above) resin to a 5-mL graduated cylinder, and fill it with water. Remove any air bubbles from the resin bed with a stainless steel wire, and settle the resin to its minimum volume by tapping the graduated cylinder. Record the volume of the resin.

Transfer the resin with 100 mL of water to a 250-mL flask. Add 2 mL of sulfuric acid, heat to 70° to 80°, and hold at that temperature for 5 minutes with occasional stirring (do not boil). Cool to room temperature, and add 2.5 mL of nitric acid (1 in 2), 2 mL of ferric ammonium sulfate TS, and 0.20 mL of 0.1 N ammonium thiocyanate. Titrate with 0.1 N silver nitrate VS until the solution turns colorless, and add a measured excess (1 to 5 mL). Heat to boiling to coagulate the silver chloride precipitate. Cool to room temperature, add 10 mL of nitrobenzene, shake vigorously, and titrate the excess silver nitrate with 0.1 N ammonium thiocyanate VS.

$$(\text{net mL AgNO}_3 \times N)/(\text{mL of resin}) = \text{mEq/mL}$$

The total exchange capacity of the regenerated, wet resin is more than 1.0 mEq per mL.

Wet screen analysis—The purpose of this test is to identify properly the mesh size of the resin. To obtain an accurate screen analysis requires special apparatus and technique.

Add 150 mL of resin to 200 mL of distilled water in an appropriate bottle, and allow it to stand at least 4 hours to completely swell the resin.

Transfer by means of a graduated cylinder 100 mL of settled and completely swollen resin to the top screen of a series (20-, 50-, 100-mesh) of 20.3-cm brass screens. Thoroughly wash the resin on each screen with a stream of distilled water until the resin is completely classified, collecting the wash water in a suitable container. Wash the beads remaining on the respective screens back into the 100-mL cylinder, and record the volume of settled resin on each screen: not less than 80% of the resin is between 50- and 100-mesh.

p-Anisaldehyde (*4-Methoxybenzaldehyde*), $C_8H_8O_2$ —**136.15** [123-11-5]—Clear, colorless liquid.

Boiling temperature: 248°.

Density: between 1.119 and 1.123.

Refractive index (831): between 1.5725 and 1.5730 at 20°.

p-Anisidine, C_7H_9NO —**123.06** [104-94-9]—Brown crystals. Use a suitable grade.

Anisole, $CH_3OC_6H_5$ —**108.14** [100-66-3]—Colorless liquid.

Assay—Inject an appropriate specimen (about 0.5 μ L) into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, nitrogen being used as the carrier gas. The following conditions have been found suitable: a 30-m capillary column is coated with phase G3; the injection port and detector temperatures are maintained at 140° and 300°, respectively; the column temperature is maintained at 70° and programmed to rise 10° per minute to 170°. The area of the anisole peak is not less than 99% of the total peak area.

Refractive index (831): 1.5160 at 20°.

Anthracene, $C_{14}H_{10}$ —**178.23** [120-12-7]—White to off-white crystals or platelets. Darkens in sunlight. Insoluble in water; sparingly soluble in alcohol, in benzene, and in chloroform.

Melting range (741): between 215° and 218°.

Anthrone, $C_{14}H_{10}O$ —**194.23** [90-44-8]—Use ACS reagent grade.

Anti-D Reagent—The reagent can be monoclonal (low protein) or polyclonal (high-protein) and must be obtained from manufacturers or suppliers licensed by the Center for Biologics Evaluation and Research, Food and Drug Administration. The use of reagents from an unlicensed manufacturer or supplier may invalidate the results. Note that this reagent is different from Anti-D (Rh_o) Reagent. Consult manufacturer's package insert to ensure that the reagent is suitable for the Weak Anti-D test and does not contain other antibodies that will react when antihuman immunoglobulin is added.

[NOTE—There are many manufacturers and suppliers of these reagents that are licensed by the Center for Biologics Evaluation and Research, Food and Drug Administration. Some examples of licensed manufacturers or suppliers are the following: Gamma Biologics, Houston, TX; and Ortho Diagnostics, Raritan, NJ.]

Anti-D (Rh_o) Reagent—The reagent can be monoclonal or polyclonal and must be obtained from manufacturers or suppliers licensed by the Center for Biologics Evaluation and Research, Food and Drug Administration for use in microplate tests. The use of reagents from an unlicensed manufacturer or supplier may invalidate the results. Note that this reagent is different from Anti-D Reagent. Consult manufacturer's package insert to ensure that it is Anti-D (Rh_o) Reagent and not Anti-D Reagent.

[NOTE—There are many manufacturers and suppliers of these reagents that are licensed by the Center for Biologics Evaluation and Research, Food and Drug Administration. Some examples of licensed manufacturers or suppliers are the following: Gamma Biologics, Houston, TX; and Ortho Diagnostics, Raritan, NJ.]

Antifoam Reagent—A 10% silicone-glycol emulsion, white in appearance. Nonionic but miscible with cool water.

[NOTE—A suitable grade is available as "Antifoam Reagent," catalog number 2210, from Dow Corning Corporation, www.dowcorning.com.]

Antihuman Globulin Reagent—The reagent can be poly-specific or anti-immunoglobulin (Anti-IgG) and must be obtained from manufacturers or suppliers licensed by the Center for Biologics Evaluation and Research, Food and Drug Administration. The use of reagents from an unlicensed manufacturer or supplier may invalidate the results.

[NOTE—There are many manufacturers and suppliers of these reagents that are licensed by the Center for Biologics Evaluation and Research, Food and Drug Administration. Some examples of licensed manufacturers or suppliers are the following: Gamma Biologics, Houston, TX; and Ortho Diagnostics, Raritan, NJ.]

Antimony Pentachloride, $SbCl_5$ —**299.02** [7647-18-9]—Clear, reddish-yellow, oily, hygroscopic, caustic liquid. Fumes in moist air and solidifies by absorption of one molecule of water. Is decomposed by water; soluble in dilute hydrochloric acid and in chloroform. Boils at about 92° at a pressure of 30 mm of mercury and has a specific gravity of about 2.34 at 25°.

[CAUTION—Antimony pentachloride causes severe burns, and the vapor is hazardous.]

Assay ($SbCl_5$)—Accurately weigh a glass-stoppered, 125-mL flask, quickly introduce about 0.3 mL of the test specimen, and reweigh. Dissolve with 20 mL of diluted hydrochloric acid (1 in 5), and add 10 mL of potassium iodide solution (1 in 10) and 1 mL of carbon disulfide. Titrate the liberated iodine with 0.1 N sodium thiosulfate VS. The brown color will gradually disappear from the solution, and the last traces of free iodine will be collected in the carbon disulfide, giving a pink color. When this pink color disap-

pears the endpoint has been reached. Each mL of 0.1 N sodium thiosulfate is equivalent to 14.95 mg of $SbCl_5$; not less than 99.0% of $SbCl_5$ is found.

Sulfate (Reagent test, *Method II*)—Dissolve 4.3 mL (10 g) in the minimum volume of hydrochloric acid, dilute with water to 150 mL, neutralize with ammonium hydroxide, and filter. To the filtrate add 2 mL of hydrochloric acid: the solution, 10 mL of barium chloride TS being used, yields not more than 1.3 mg of residue, correction being made for a complete blank test (0.005%).

Arsenic—Add 10 mL of a recently prepared solution of 20 g of stannous chloride in 30 mL of hydrochloric acid to 100 mg of specimen dissolved in 5 mL of hydrochloric acid. Mix, transfer to a color-comparison tube, and allow to stand for 30 minutes. Any color in the solution of the specimen should not be darker than that in a control containing 0.02 mg of arsenic (As), which has been treated in the same manner as the test specimen, when viewed downward over a white surface (0.02% of As).

Substances not precipitated by hydrogen sulfide (as SO_4)—Dissolve 0.90 mL (2 g) in 5 mL of hydrochloric acid, and dilute with 95 mL of water. Precipitate the antimony completely with hydrogen sulfide, allow the precipitate to settle, and filter, being careful not to transfer much of the precipitate to the filter paper. (Retain the precipitate.) To 50 mL of the filtrate, add 0.5 mL of sulfuric acid, evaporate in a tared porcelain crucible to dryness, and ignite at $800 \pm 25^\circ$ for 15 minutes. (Retain the residue.) The weight of the ignited residue should not be more than 0.0010 g greater than the weight obtained in a complete blank test (0.10%).

Iron (241)—To the residue from the test for *Substances not precipitated by hydrogen sulfide* add 2 mL of hydrochloric acid and 5 drops of nitric acid, and evaporate on a steam bath to dryness. Take up the residue in 2 mL of hydrochloric acid, and dilute with water to 47 mL: the solution shows not more than 0.01 mg of Fe (0.001%).

Other heavy metals (as Pb)—Dissolve the precipitate on the filter paper from the test for *Substances not precipitated by hydrogen sulfide*, with 75 mL of a solution containing 6 g of sodium sulfide and 4 g of sodium hydroxide dissolved in and diluted with water to 100 mL. Collect the filtrate in the original flask containing the remainder of the sulfide precipitate. Warm the solution to dissolve the soluble sulfides, and allow the insoluble sulfides to settle. Filter, wash thoroughly with hydrogen sulfide TS, and dissolve any precipitate remaining on the filter paper with 10 mL of hot diluted hydrochloric acid. Dilute the filtrate with water to 50 mL. Neutralize a 25-mL portion of this solution with 1 N sodium hydroxide, and add 1 mL of 1 N acetic acid and 10 mL of hydrogen sulfide TS. Any brown color should not exceed that produced by 0.05 mg of lead ion in an equal volume of solution containing 1 mL of 1 N acetic acid and 10 mL of hydrogen sulfide TS (0.005%).

Antimony Trichloride (*Antimonous Chloride*), $SbCl_3$ —**228.12** [10025-91-9]—Use ACS reagent grade.

Antithrombin III—Antithrombin III human (heparin cofactor, factor II_a inhibitor, and factor X_a inhibitor) is a serine protease inhibitor. It is a glycoprotein having a molecular weight of 58,000 Da.

One Antithrombin III Unit is the amount found in 1 mL of normal human plasma. The potency of antithrombin III is not less than 4.0 Antithrombin III Units per mg of protein when tested in the presence of heparin. It exhibits 90% homogeneity when tested by SDS-PAGE.

Antithrombin III for test or assay purposes contains no detectable heparin. Test as follows. To a solution containing 1 Antithrombin III Unit per mL, add 1 μ L of toluidine blue solution. In the presence of heparin, the color changes from blue to purple.

Aprobarbital, $C_{10}H_{14}N_2O_3$ —**210.23** [77-02-1]—Fine, white crystalline powder. Slightly soluble in cold water; soluble in alcohol, in chloroform, and in ether.

Assay—Dissolve about 200 mg, previously dried at 105° for 2 hours and accurately weighed, in 20 mL of dimethylformamide in a 100-mL conical flask. Add 4 drops of thymol blue solution (1 in 200 in methanol), and titrate with 0.1 N lithium methoxide VS using a 10-mL buret, a magnetic stirrer, and a cover for the flask to protect against atmospheric carbon dioxide. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N lithium methoxide is equivalent to 21.02 mg of $C_{10}H_{14}N_2O_3$. Between 98.5% and 101.0% of $C_{10}H_{14}N_2O_3$ is found.

Melting range (741): between 140° and 143°.

Arsenazo III Acid, $C_{22}H_{18}As_2N_4O_{14}S_2$ —**776.38** [1668-00-4]—Brown powder. Stable in air. Store at room temperature in a dry area.

Melting temperature (741): greater than 320°.

Arsenic Trioxide, As_2O_3 —**197.84** [1327-53-3]—Use ACS reagent grade.

[NOTE—Arsenic Trioxide of a quality suitable as a primary standard is available from the National Institute of Standards and Technology, Office of Standard Reference Materials, www.nist.gov, as standard sample No. 83.]

L-Asparagine (*L*-2-Aminosuccinamic Acid), $COOHCH(NH_2)CH_2CONH_2 \cdot H_2O$ —**150.13** [70-47-3]—Colorless crystals. One g dissolves in 50 mL of water; soluble in acids and in alkalis; insoluble in alcohol and in ether. Its neutral or alkaline solutions are levorotatory; its acid solutions are dextrorotatory.

Specific rotation (781): between +31° and +33°, determined in a solution in diluted hydrochloric acid containing the equivalent of 5 g (on the anhydrous basis, as determined by drying at 105° for 5 hours) in each 100 mL.

Residue on ignition (Reagent test): not more than 0.1%.

Chloride (Reagent test)—One g shows not more than 0.03 mg of Cl (0.003%).

Sulfate (Reagent test, *Method I*)—One g shows not more than 0.05 mg of SO_4 (0.005%).

Heavy metals (Reagent test): 0.002%.

Nitrogen content, Method II (461): between 18.4% and 18.8% of N is found.

L-Aspartic Acid, $C_4H_7NO_4$ —**133.1** [56-84-8]—White to off-white powder. Use a suitable grade.

Azure A, $C_{14}H_{14}ClN_3S$ —**291.80** [531-53-3]—Use a suitable grade.

Bacterial Alkaline Protease Preparation—Use a suitable grade.

[NOTE—A suitable grade is commercially available as “Protex 6L” from Genencor, www.genencor.com, or as “Optimase Enzyme” from Solvay Enzymes Inc., www.solvaypharmaceuticals.com.]

Barbital Sodium, $C_8H_{11}N_2NaO_3$ —**206.2** [144-02-5]—White, crystalline powder or colorless crystals. Freely soluble in water; slightly soluble in alcohol. Use a suitable reagent grade.

Barbituric Acid, $C_4H_4N_2O_3$ —**128.09** [65-52-7]—Faintly beige powder. Soluble in water, in alcohol, in chloroform, and in ether. Melts with decomposition at 251.6°. Use a suitable grade.

Barium Acetate, $C_4H_6BaO_4$ —**255.43** [543-80-6]—Use ACS reagent grade.

Barium Chloride, $BaCl_2 \cdot 2H_2O$ —**244.26**

[10326-27-9]—Use ACS reagent grade.

Barium Chloride, Anhydrous, $BaCl_2$ —**208.23** [10361-37-2]—This may be made by drying barium chloride in thin layers at 125° until the loss in weight between two successive, 3-hour drying periods does not exceed 1%.

Barium Chloride Dihydrate—Use *Barium Chloride*.

Barium Hydroxide, $Ba(OH)_2 \cdot 8H_2O$ —**315.46**

[12230-71-6]—Use ACS reagent grade.

Barium Nitrate, $Ba(NO_3)_2$ —**261.34** [10022-31-8]—Use ACS reagent grade.

Basic Fuchsin—See *Fuchsin, Basic*.

Beclomethasone $C_{22}H_{29}ClO_5$ —**408.92** [4419-39-0]—Use a suitable grade with a content of not less than 99%.

Beef Extract—A concentrate from beef broth obtained by extraction from fresh, sound, lean beef by means of cooking with water and evaporating the broth at a low temperature, usually in vacuum, until a thick, pasty residue results. Yellowish brown to dark brown, slightly acid, pasty mass having an agreeable meat-like odor. Store it in tight, light-resistant containers.

For the following tests, prepare a *test solution* by dissolving 25 g in water to make 250 mL of a practically clear and practically sediment-free solution.

Assay for nitrogen content of alcohol-soluble substances—Place a portion of the alcohol filtrate and washings remaining from the test for *Alcohol-insoluble substances*, corresponding to 1 g of the alcohol-soluble solids, in a 500-mL Kjeldahl flask. Add about 10 g of powdered potassium sulfate and 20 mL of sulfuric acid. Heat the mixture at a low temperature until frothing ceases, then raise the temperature and boil until the mixture acquires a pale yellow color or becomes practically colorless. Cool the flask, add about 250 mL of water, and cautiously add sodium hydroxide solution (3 in 10) until the contents are alkaline, then add 5 mL more. Connect the flask at once by means of a spray trap to a condenser, the lower outlet tube of which dips beneath the surface of 50.0 mL of 0.1 N sulfuric acid VS contained in a receiving flask. Distill the mixture until about 100 mL of distillate has been collected in the acid. Add methyl red TS, and titrate the excess acid with 0.1 N sodium hydroxide VS. Each mL of 0.1 N sulfuric acid is equivalent to 1.401 mg of N. Not less than 60 mg of nitrogen is found.

Assay for nitrogen as ammonia—To 100 mL of *test solution*, contained in a 500-mL Kjeldahl flask, add 5 g of barium carbonate and 100 mL of water, and by means of a spray trap, connect the flask to a condenser, the lower outlet tube of which dips beneath the surface of 50.0 mL of 0.1 N sulfuric acid VS contained in a receiving flask. Distill the mixture until about 100 mL of distillate has been collected, add methyl red TS, and titrate the excess acid with 0.1 N sodium hydroxide VS. Each mL of 0.1 N sulfuric acid is equivalent to 1.703 mg of NH_3 . The amount of ammonia found does not exceed 0.35% of the total solids in the portion of *test solution* taken.

Total solids—Distribute 10 mL of *test solution* over clean, dry sand or asbestos, tared in a porcelain dish, and dry at 105° for 16 hours: the residue weighs not less than 750 mg (75%).

Residue on ignition—Incinerate the residue obtained in the test for *Total solids* by heating the dish to a dull-red heat: the residue does not exceed 30% of the total solids.

Chlorides calculated as sodium chloride—Dissolve the ash obtained in the test for *Residue on ignition* in about 50 mL of water, and carefully transfer to a 100-mL volumetric flask. Add to the solution a few drops of nitric acid and 10.0 mL of 0.1 N silver nitrate VS. Add water to volume, and mix. Filter into a dry flask through a dry filter, rejecting the first 10 mL of the filtrate. To 50.0 mL of the subsequent filtrate add 1 mL of ferric ammonium sulfate TS, and titrate with 0.1 N ammonium thiocyanate VS. Each mL of 0.1 N silver nitrate is equivalent to 5.844 mg of NaCl. The weight of chlorides calculated as sodium chloride obtained, when multiplied by 2, does not exceed 6% of the total solids.

Alcohol-insoluble substances—Transfer 25 mL of *test solution* to a 100-mL conical flask, add 50 mL of alcohol, and shake thoroughly. Collect the precipitate on a counterpoised filter, wash it three times with a mixture of 2 volumes of

alcohol and 1 volume of water, and dry at 105° for 2 hours: the weight of the precipitate, representing the alcohol-insoluble solids, does not exceed 10% of the total solids in the portion of test solution taken.

Nitrate—Boil 10 mL of test solution for 1 minute with 1.5 g of activated charcoal, add water to replace that lost by evaporation, filter, and add 1 drop of the filtrate to 3 drops of a 1 in 100 solution of diphenylamine in sulfuric acid: no blue color is produced.

Benzaldehyde, C_7H_6O —**106.12** [100-52-7]—Colorless, strongly refractive liquid. Soluble in water; miscible with alcohol, with ether, and with fixed and volatile oils.

Assay—Pipet about 1 mL into a tared, glass-stoppered weighing bottle, and weigh accurately. Loosen the stopper, and transfer both the weighing bottle and its contents to a 250-mL conical flask containing 25 mL of a hydro-alcoholic solution of hydroxylamine hydrochloride (prepared by dissolving 34.7 g of hydroxylamine hydrochloride in 160 mL of water, then adding alcohol to make 1000 mL, and neutralizing to bromophenol blue by the addition of sodium hydroxide TS). Using a graduated cylinder to measure the volume, rinse the sides of the flask with an additional 50 mL of this reagent solution. Allow the solution to stand for 10 minutes, add 1 mL of bromophenol blue TS, and titrate the liberated hydrochloric acid with 1 N sodium hydroxide VS. Perform a blank determination with the same quantities of the same reagents, and make any necessary correction. Each mL of 1 N sodium hydroxide consumed is equivalent to 106.1 mg of C_7H_6O . Not less than 98% is found.

Specific gravity (841): between 1.041 and 1.046.

Refractive index (831): between 1.5440 and 1.5465 at 20°.

Hydrocyanic acid—Shake 0.5 mL with 5 mL of water, add 0.5 mL of sodium hydroxide TS and 0.1 mL of ferrous sulfate TS, and warm the mixture gently. Add a slight excess of hydrochloric acid: no greenish-blue color or blue precipitate is observed within 15 minutes.

Benzalkonium Chloride—Use *Benzalkonium Chloride* (NF monograph).

Benzamidinium Hydrochloride Hydrate (*Benzenecarboximidamide Monohydrochloride, Hydrate*), $C_7H_8N_2 \cdot HCl \cdot xH_2O$ —**156.6** [206752-36-5]—White to off-white powder. Use a suitable grade.

[NOTE—A suitable grade is available from Sigma-Aldrich, www.sigma-aldrich.com.]

Benzanilide, $C_{13}H_{11}NO$ —**197.23** [93-98-1]—Off-white, light gray to grayish-green powder. Insoluble in water; sparingly soluble in alcohol; slightly soluble in ether.

Melting range (741): between 162° and 165°.

Solubility in acetone—A 1.0-g portion dissolves completely in 50 mL of acetone to yield a clear solution.

Benzene, C_6H_6 —**78.11** [71-43-2]—Use ACS reagent grade.

Benzenesulfonamide, $C_6H_5SO_2NH_2$ —**157.19** [98-10-2]—White to pale beige crystals.

Melting range (741): between 150° and 153°.

Benzenesulfonyl Chloride, $C_6H_5SO_2Cl$ —**176.62** [98-09-9]—Colorless, oily liquid. Insoluble in cold water; soluble in alcohol and in ether. Solidifies at 0°.

Melting range (741): between 14° and 17°.

Boiling range (Reagent test): between 251° and 252°.

Benzhydrol (α -Phenylbenzenemethanol), $C_{13}H_{12}O$ —**184.23** [91-01-0]—White to pale yellow crystals. Very slightly soluble in water; soluble in alcohol, in ether, and in chloroform.

Melting range (741): between 65° and 67°, but the range between beginning and end of melting does not exceed 2°.

Benzoic Acid, C_6H_5COOH —**122.12** [65-85-0]—Use ACS reagent grade.

[NOTE—Benzoic Acid of a quality suitable as a primary standard is available from the National Institute of Standards

and Technology, Office of Standard Reference Materials, www.nist.gov, as standard sample No. 350.]

Benzophenone, $(C_6H_5)_2CO$ —**182.22** [119-61-9]—White, crystalline powder.

Melting range (741): between 47° and 49°.

p-Benzoquinone (*Quinone*), $C_6H_4O_2$ —**108.09** [106-51-4]—Dark yellow powder having a green cast. Slightly soluble in water; soluble in alcohol, in ether, and in fixed alkali solutions. May darken on standing. Darkened material may be purified by sublimation in vacuum.

Melting range (741): between 113° and 115°.

Benzoyl Chloride, C_6H_5COCl —**140.57** [98-88-4]—Use ACS reagent grade.

N-Benzoyl-L-arginine Ethyl Ester Hydrochloride, $C_{15}H_{22}N_4O_3 \cdot HCl$ —**342.82**—Determine suitability for use as a substrate as directed under *Crystallized Trypsin* (USP monograph).

3-Benzoylbenzoic Acid, $C_{14}H_{10}O_3$ —**226.23** [579-18-0]—White to off-white powder.

Assay—Prepare a mixture of 1% trifluoroacetic acid in water and 1% trifluoroacetic acid in acetonitrile (55:45) for the mobile phase. Inject about 20 μ L into a suitable liquid chromatograph (see *Chromatography* (621)) equipped with a 230-nm detector and a 4.6-mm \times 15-cm column that contains packing L1. The flow rate is about 1.5 mL per minute. The area of the $C_{14}H_{10}O_3$ peak is not less than 98.5% of the total peak area.

Benzoylformic Acid (*Phenylglyoxylic Acid*), $C_6H_5COCO_2H$ —**150.14** [611-73-4]—Powder. Soluble in methanol.

Melting range (741): between 62° and 67°.

Benzphetamine Hydrochloride, $C_{17}H_{21}N \cdot HCl$ —**275.82** [5411-22-3]—White to off-white, crystalline powder. Freely soluble in water, in alcohol, and in chloroform; slightly soluble in ether.

Assay—Dissolve about 500 mg, accurately weighed, in a mixture of 50 mL of glacial acetic acid and 10 mL of mercuric acetate TS, add 1 drop of crystal violet TS, and titrate with 0.1 N perchloric acid VS to a blue-green endpoint. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N perchloric acid is equivalent to 27.58 mg of $C_{17}H_{21}N \cdot HCl$. Between 98.0% and 101.0%, calculated on the dried basis, is found.

Melting range (741): between 152° and 158°.

Specific rotation (781): between +22° and +26°, determined in a solution containing 200 mg in 10 mL, the specimen having been previously dried in vacuum at 60° for 3 hours.

Loss on drying (731)—Dry it in vacuum at 60° for 3 hours: it loses not more than 1% of its weight.

Residue on ignition (281): not more than 0.2%.

2-Benzylaminopyridine, $C_{12}H_{12}N_2$ —**184.24** [6935-27-9]—Use a suitable grade.

1-Benzylimidazole, $C_{10}H_{10}N_2$ —**158.20** [4238-71-5]—White crystals.

Assay—Transfer about 40 mg, accurately weighed, to a 100-mL beaker. Dissolve in 50 mL of glacial acetic acid. Titrate with 0.1 N perchloric acid VS, determining the endpoint potentiometrically using a combination calomel-platinum electrode. Perform a blank determination and make any necessary correction. Each mL of 0.1 N perchloric acid is equivalent to 15.82 mg of $C_{10}H_{10}N_2$. Not less than 99% is found.

Benzyltrimethylammonium Chloride, $C_6H_5CH_2N(CH_3)_3Cl$ —**185.69** [56-93-9]—Available as a 60% aqueous solution. Is clear and is colorless or not more than slightly yellow.

Assay—Pipet 2 mL into a 50-mL volumetric flask, and add water to volume. Pipet 20 mL of the solution into a 125-mL conical flask, add about 30 mL of water, then add 0.25 mL of dichlorofluorescein TS, and titrate with 0.1 N silver nitrate

VS. Each mL of 0.1 N silver nitrate is equivalent to 18.57 mg of $C_6H_5CH_2N(CH_3)_3Cl$. Between 59.5% and 60.5% is found.

Beta-lactamase—Beta-lactamase is an enzyme produced by a variety of bacteria, but is usually obtained from culture filtrates of a strain of *Bacillus cereus*. It has the specific property of inactivating penicillins and cephalosporins by splitting the bond linking the nitrogen of the thiazolidine to the adjacent carbonyl carbon.

It occurs in the form of small, brown, easily pulverizable pieces or granules. Freely soluble in water, forming a slightly opalescent solution that is practically neutral to litmus paper. Is precipitated from its water solutions by acetone, by alcohol, and by dioxane, and is inactivated by contact with these solvents. Is rapidly inactivated by ethyl acetate and is irreversibly destroyed at a temperature of about 80°.

Beta-lactamase is assayed by a procedure depending upon a determination of the amount of penicillin G potassium or penicillin G sodium destroyed at a pH of 7.0 in a solution of such concentration that the inactivation proceeds as a zero-order reaction.

Betanaphthol—See 2-Naphthol.

Bibenzyl (Dibenzyl), $C_{14}H_{14}$ —**182.26** [103-29-7]—Colorless crystals. Freely soluble in chloroform and in ether; sparingly soluble in alcohol; practically insoluble in water.

Melting range (741): between 53° and 55°.

Bile Salts—A concentrate of beef bile, the principal constituent of which is sodium desoxycholate, determined as cholic acid. Soluble in water and in alcohol; the solutions foam strongly when shaken.

Insoluble substances—Dissolve 5 g in 100 mL of dilute alcohol (84 in 100), warming if necessary to aid solution. Filter within 15 minutes through a tared filter, and wash with small portions of the dilute alcohol until the last washing is colorless or practically so, then dry the residue at 105° for 1 hour, and weigh: the weight of the residue does not exceed 0.1%.

Assay—

STANDARD CHOLIC ACID SOLUTION—Dissolve 50.0 mg of cholic acid, accurately weighed, in dilute acetic acid (6 in 10) to make 100 mL, and mix. Store in a refrigerator.

PROCEDURE—Dissolve 1.0 g, accurately weighed, in 50 mL of dilute acetic acid (6 in 10). Filter the solution, if necessary, into a 100-mL volumetric flask, wash the original container and the filter with small portions of dilute acetic acid (6 in 10), add the same acetic acid to volume, and mix. Dilute 10 mL of this solution, accurately measured, with dilute acetic acid (6 in 10) to make 100 mL, and mix.

Pipet 1 mL each of the *Standard Cholic Acid Solution* and the solution of the Bile Salts into two matched test tubes. To each tube add 1 mL, accurately measured, of freshly prepared furfural solution (1 in 100), immediately place the tubes in an ice-bath for 5 minutes, then add to each tube 13 mL, accurately measured, of dilute sulfuric acid, made by cautiously mixing 50 mL of sulfuric acid with 65 mL of water. Mix the contents of the tubes, and place them in a water bath maintained at a temperature of 70° for 10 minutes. Immediately transfer the tubes to an ice-bath for 2 minutes, then determine the absorbance of each solution at the wavelength of maximum absorbance at about 670 nm, with a suitable spectrophotometer. Calculate the quantity, in mg, of cholic acid ($C_{24}H_{40}O_5$) in the weight of the Bile Salts taken by the formula:

$$500(A_u/A_s)$$

in which A_u and A_s are the absorbances of the solutions from the Bile Salts and the *Standard Cholic Acid Solution*, respectively. Not less than 45% of cholic acid is found.

Biphenyl, $C_{12}H_{10}$ —**154.21** [92-52-4]—Colorless to white crystals or crystalline powder. Insoluble in water; soluble in alcohol and in ether. Boils at about 254°.

Melting range (741): between 68° and 72°.

2,2'-Bipyridine (α,α' -Dipyridyl), $C_{10}H_8N_2$ —**156.18** [366-18-7]—White or pink, crystalline powder. Soluble in water and in alcohol. Melts at about 69°, and boils at about 272°.

Sensitivity—Prepare the following solutions: (A)—Dissolve 350 mg of ferrous ammonium sulfate in 50 mL of water containing 1 mL of sulfuric acid, and add 500 mg of hydrazine sulfate, then add water to make 500 mL. For use, dilute this solution with water in the ratio of 1 in 100 mL. (B)—Dissolve 8.3 g of sodium acetate and 12 mL of glacial acetic acid in water to make 100 mL. Add 1 mL of a solution of the specimen (1 in 1000) to a mixture of 10 mL of water and 1 mL of each of solutions A and B: a pink color results immediately.

Solubility—A 100-mg portion dissolves completely in 10 mL of water.

Residue on ignition (Reagent test): not more than 0.2%.

4,4'-Bis(4-amino-1-naphthylazo)-2,2'-stilbenedisulfonic Acid, $C_{34}H_{26}N_6O_6S_2$ —**678.74** [5463-64-9]—Use a suitable grade.

[NOTE—A suitable grade is available from TCI America, www.tciamerica.com.]

Bis(2-ethylhexyl) Maleate, $C_{20}H_{36}O_4$ —**340.50** [142-16-5]—Colorless to pale yellow, clear liquid. Miscible with acetone and with alcohol. Specific gravity about 0.945.

Assay—Place about 2.5 g, accurately weighed, in a 250-mL flask, add 50.0 mL of 0.5 N alcoholic potassium hydroxide VS, and reflux for 45 minutes. Cool, add 0.5 mL of phenolphthalein TS, and titrate the excess alkali with 0.5 N hydrochloric acid VS. Perform a blank determination at the same time, using the same amount of 0.5 N alcoholic potassium hydroxide (see *Residual Titrations under Titrimetry* (541)). The difference, in mL, between the volumes of 0.5 N hydrochloric acid consumed in the test titration and blank titration, multiplied by 85.1, represents the quantity, in mg, of bis(2-ethylhexyl) maleate in the portion taken. Not less than 97% is found.

Bis(2-ethylhexyl) Phthalate, $C_{6}H_4-1,2-[COOCH_2(C_2H_5)CH(CH_2)_3CH_3]_2$ —**390.56** [117-81-7]—Colorless to light yellow liquid.

Refractive index (831): between 1.4855 and 1.4875, at 20°.

Bis(2-ethylhexyl) Sebacate (Diocetyl Sebacate), $C_8H_{17}OOC(CH_2)_8COOC_8H_{17}$ —**426.67** [122-62-3]—Pale straw-colored liquid. Insoluble in water. Refractive index about 1.448. Suitable for use in gas chromatography.

Specific gravity, 20°/20°(841): between 0.913 and 0.917.

Boiling range: between 243° and 248° at 5 mm of mercury.

[NOTE—A suitable grade is "Diocetyl Sebacate," available from Sigma-Aldrich, www.sigma-aldrich.com.]

Bis(2-ethylhexyl)phosphoric Acid [Bis(2-ethylhexyl)Phosphate], $[CH_3(CH_2)_3CH(CH_2)_3CH_2]_2HPO_4$ —**322.42** [298-07-7]—Light yellow, viscous liquid. Insoluble in water; freely soluble in chloroform and in ethyl acetate. Refractive index: about 1.443. Specific gravity: about 0.997.

Assay—Dissolve about 250 mg, accurately weighed, in 50 mL of dimethylformamide, add 3 drops of a 1 in 100 solution of thymol blue TS in dimethylformamide, and titrate with 0.1 N sodium methoxide VS to a blue endpoint. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N sodium methoxide is equivalent to 32.24 mg of $(C_8H_{17})_2HPO_4$. Between 95% and 105% is found.

Solubility—One volume dissolves in 9 volumes of chloroform to yield a clear solution, and 1 volume dissolves in 9 volumes of ethyl acetate to yield a clear solution.

Color—A 1 in 100 solution in chloroform exhibits an absorptivity of not more than 0.03 at 420 nm.

Bis(4-sulfobutyl) Ether Disodium, $\text{Na}_2\text{C}_8\text{H}_{16}\text{O}_7\text{S}_2$ —**334.32**—Use a suitable grade with a content of NLT 95%.

[NOTE—A suitable grade is available as catalog number RM-969-C50 from www.cydexpharma.com.]

Bismuth Nitrate Pentahydrate, $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$ —**485.07** [10035-06-0]—Use ACS reagent grade.

Bismuth Subnitrate (*Bismuth(III) Nitrate Basic*), $\text{Bi}_2\text{O}(\text{OH})(\text{NO}_3)_4$ —**1461.99** [1304-85-4]—Use *Bismuth Subnitrate* (USP monograph).

Bismuth Sulfite Agar—Use a suitable grade.

Bis(trimethylsilyl)acetamide (*N,O-Bis(trimethylsilyl)acetamide*; *BSA*), $\text{CH}_3\text{CON}[\text{Si}(\text{CH}_3)_3]_2$ —**203.43** [10416-59-8]—Clear, colorless liquid. Readily hydrolyzes when exposed to moist air. Handle under nitrogen, and store in a cool place.

Assay—Not less than 90% of $\text{CH}_3\text{CON}[\text{Si}(\text{CH}_3)_3]_2$, a suitable gas chromatograph equipped with a thermal conductivity detector being used. The following conditions are suitable and provide a retention time of approximately 15 minutes.

COLUMN: 3-mm \times 1.83-m stainless steel containing 5% phase G1 on support S1A.

INJECTION TEMPERATURE: 160°.

COLUMN TEMPERATURE: 90°, programmed to rise 4° per minute to 160°.

CARRIER GAS: Helium.

Refractive index (831): between 1.4150 and 1.4170 at 20°.

Bis(trimethylsilyl)trifluoroacetamide (*N,O-Bis(trimethylsilyl)trifluoroacetamide*; *BSTFA*), $\text{CF}_3\text{CON}[\text{Si}(\text{CH}_3)_3]_2$ —**257.40** [25561-30-2]—Clear, colorless liquid. Readily hydrolyzes when exposed to moist air. Store in a cool place.

Assay—Not less than 98% of $\text{CF}_3\text{CON}[\text{Si}(\text{CH}_3)_3]_2$, a suitable gas chromatograph equipped with a thermal conductivity detector being used. The following conditions are suitable and provide a retention time of approximately 15 minutes.

COLUMN: 3-mm \times 1.83-m stainless steel containing 5% phase G1 on support S1A.

INJECTION TEMPERATURE: 170°.

COLUMN TEMPERATURE: 70°, programmed to rise 4° per minute to 140°.

CARRIER GAS: Helium.

Refractive index (831): between 1.3820 and 1.3860 at 20°.

Bis(trimethylsilyl)trifluoroacetamide with Trimethylchlorosilane [25561-30-2]—Use a suitable grade.

[NOTE—A suitable grade is available from Sigma-Aldrich, www.sigma-aldrich.com.]

Blood (for carbon monoxide test in gases)—Use *oxalated* or *defibrinated blood* of dogs, sheep, cattle, or human beings within 24 hours after bleeding. Prepare *oxalated blood* by adding 10 mg of sodium oxalate to each mL of the freshly drawn blood.

Blood Group A₁ Red Blood Cells and Blood Group B Red Blood Cells—These cells must be obtained from manufacturers or suppliers licensed by the Center for Biologics Evaluation and Research/Food and Drug Administration. The use of reagents from an unlicensed manufacturer or supplier may invalidate the results. Generally, they are available as part of a kit for ABO Blood Group testing. The cells licensed for use in test tubes can also be used in the microtiter plate method described in the monographs of *Red Blood Cells* and *Whole Blood*.

[NOTE—There are many manufacturers and suppliers of these reagents that are licensed by the Center for Biologics Evaluation and Research/Food and Drug Administration. Some examples of licensed manufacturers or suppliers are the following: Gamma Biologics, Houston, TX; and Ortho Diagnostics, Raritan, NJ.]

Anti-A Blood Grouping Reagent, Anti-B Blood Grouping Reagent, and Anti-AB Blood Grouping Reagent—The reagents can be monoclonal or polyclonal and must be obtained from manufacturers or suppliers licensed by the Center for Biologics Evaluation and Research, Food and Drug Administration for use in microplate tests.

The use of reagents from an unlicensed manufacturer or supplier may invalidate the results. Generally, all three reagents are available as part of a kit.

[NOTE—There are many manufacturers and suppliers of these reagents that are licensed by the Center for Biologics Evaluation and Research, Food and Drug Administration. Some examples of licensed manufacturers or suppliers are the following: Gamma Biologics, Houston, TX; and Ortho Diagnostics, Raritan, NJ.]

Blue Tetrazolium (*3,3'-(3,3'-Dimethoxy[1,1'-biphenyl]-4,4'-diyl)bis[2,5-diphenyl-2H-tetrazolium]dichloride*), $\text{C}_{40}\text{H}_{32}\text{Cl}_2\text{N}_8\text{O}_2$ —**727.64** [1871-22-3]—Lemon-yellow crystals. Slightly soluble in water; freely soluble in chloroform and in methanol; insoluble in acetone and in ether.

Solubility in methanol—Dissolve 1 g in 100 mL of methanol: complete solution results, and the solution is clear.

Color—Transfer a portion of the methanol solution obtained in the preceding test to a 1-cm cell, and determine its absorbance at 525 nm, against water as the blank: the absorbance does not exceed 0.20.

Molar absorptivity (851)—Its molar absorptivity in methanol, at 252 nm, is not less than 50,000.

Suitability test—

STANDARD PREPARATION—Dissolve in alcohol a suitable quantity of USP Hydrocortisone RS, previously dried at 105° for 3 hours and accurately weighed, and prepare by stepwise dilution a solution containing about 10 μg per mL.

PROCEDURE—Pipet 10-, 15-, and 20-mL portions of *Standard Preparation* into separate, glass-stoppered, 50-mL conical flasks. Add 10 mL and 5 mL, respectively, of alcohol to the flasks containing the 10- and 15-mL portions of *Standard Preparation*, and swirl to mix. To each of the flasks, and to a fourth flask containing 20 mL of alcohol, add 2.0 mL of a solution prepared by dissolving 50 mg of blue tetrazolium in 10 mL of alcohol, mix, and then add 2.0 mL of a solution prepared by diluting 1 mL of tetramethylammonium hydroxide TS with alcohol to 10 mL. Mix, allow the flasks to stand in the dark for 90 minutes, and determine the absorbances of the three solutions of the steroid standard at 525 nm, with a suitable spectrophotometer, using the solution in the fourth flask as the blank. Plot the absorbances on the abscissa and the amount of hydrocortisone on the ordinate scale of arithmetic coordinate paper, and draw the curve of best fit: the absorbance of each solution is proportional to the concentration, and the absorbance of the solution containing 200 μg of hydrocortisone is not less than 0.50.

Boric Acid, H_3BO_3 —**61.83** [10043-35-3]—Use ACS reagent grade.

(-)-Bornyl Acetate (*1,7,7-Trimethylbicyclo[2,2,1]-heptan-2-ol acetate*), $\text{C}_{12}\text{H}_{20}\text{O}_2$ —**196.29** [5655-61-8]—Use a suitable grade.

Boron Trifluoride, BF_3 —**67.81** [7637-07-2]—Use a suitable grade.

14% Boron Trifluoride-Methanol [373-57-9]—Use a suitable grade.

Bovine Collagen—Use a suitable grade that contains less than 1 μg glycosaminoglycan per mg.

[NOTE—A suitable grade is available from Sigma-Aldrich, www.sigma-aldrich.com.]

7 Percent Bovine Serum Albumin Certified Standard—Available from the National Institute of Standards and Technology, www.nist.gov, as SRM 927.

Branched Polymeric Sucrose—about 400 kDa [26873-85-8]—White to off-white powder. Synthetic polymer made by the copolymerization of sucrose and epichlorohydrin. Use a suitable grade.

[NOTE—A suitable grade is available commercially as "Ficoll" from Pharmacia Fine Chemicals, Inc., 800 Centennial Ave., Piscataway, NJ 08854.]

Brilliant Green (*Malachite Green G*), $C_{27}H_{34}N_2O_4S$ —**482.64** [3051-11-4]—Glistening, golden-yellow crystals. Soluble in water and in alcohol. Absorption maximum: 623 nm.

Bromelain—A proteolytic enzyme isolated from pineapple. Use a suitable grade.

Bromine, Br—At. Wt. 79.904 [7726-95-6]—Use ACS reagent grade.

α -Bromo-2'-acetophenone (*Bromomethyl 2-naphthyl ketone*), $C_{12}H_9BrO$ —**249.10**—Tannish-pink crystals.

Melting range (741): between 81° and 83°.

***p*-Bromoaniline**, C_6H_6BrN —**172.02** [106-40-1]—White to off-white crystals. Insoluble in water; soluble in alcohol and in ether.

Assay—Transfer about 650 mg, accurately weighed, to a suitable container, and dissolve in 50 mL of glacial acetic acid TS. Add crystal violet TS, and titrate with 0.1 N perchloric acid VS. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N perchloric acid is equivalent to 17.20 mg of C_6H_6BrN . Not less than 98% is found.

Melting range (741): between 60° and 65°, within a 2° range.

Bromofluoromethane—Use a suitable grade.

***N*-Bromosuccinimide**, $C_4H_4BrNO_2$ —**177.98** [128-08-5]—White to off-white crystals or powder. Freely soluble in water, in acetone, and in glacial acetic acid. [CAUTION—Highly irritating to eyes, skin, and mucous membranes.]

Assay—Transfer 200 mg, accurately weighed, to a conical flask, add 25 mL of 0.5 N alcoholic potassium hydroxide, cover with a watch glass, heat to boiling, and boil for 5 minutes. Cool, transfer the solution to a beaker, rinsing the flask with water until the total volume of solution plus rinsings is about 100 mL, and add 10 mL of glacial acetic acid. Insert suitable electrodes, and titrate with 0.1 N silver nitrate VS, determining the endpoint potentiometrically. Each mL of 0.1 N silver nitrate is equivalent to 17.80 mg of $C_4H_4BrNO_2$. Not less than 98% is found.

Bromine Sulfate, $(C_{23}H_{26}N_2O_4)_2 \cdot H_2SO_4 \cdot 7H_2O$ —**1013.11** [5787-00-8]—Use ACS reagent grade.

Buffers—See *Buffer Solutions* under *Solutions*.

1,3-Butanediol (*1,3-Butylene Glycol*), $C_4H_{10}O_2$ —**90.12** [107-88-0]—Viscous, colorless liquid. Very hygroscopic. Soluble in water, in alcohol, in acetone, and in methyl ethyl ketone; practically insoluble in aliphatic hydrocarbons, in benzene, and in toluene.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 3-mm \times 1.8-m stainless steel column containing 20% phase G16 on support S1A; the injection port temperature is maintained at 265°; the column temperature is maintained at 150° and programmed to rise 8° per minute to 210°. The area of the butanediol peak is not less than 98% of the total peak area.

Refractive index (831): between 1.4390 and 1.4410 at 20°.

2,3-Butanedione (*Diacetyl*), $CH_3COCOCH_3$ —**86.09** [431-03-8]—Bright yellow to yellowish-green liquid. Soluble

in water. Miscible with alcohol and with ether. Boils at about 88°.

Assay—

HYDROXYLAMINE HYDROCHLORIDE SOLUTION—Dissolve 20 g of hydroxylamine hydrochloride in 40 mL of water, and dilute with alcohol to 400 mL. Add, with stirring, 300 mL of 0.5 N alcoholic potassium hydroxide VS, and filter. Discard after 2 days.

PROCEDURE—Transfer about 1 g, accurately weighed, to a glass-stoppered, 250-mL flask, add 75.0 mL of *Hydroxylamine hydrochloride solution*, and insert the stopper in the flask. Reflux the mixture for 1 hour, then cool to room temperature. Add bromophenol blue TS, and titrate with 0.5 N hydrochloric acid VS to a greenish-yellow endpoint. [NOTE—Alternatively, the solution may be titrated potentiometrically to a pH of 3.4.] Perform a blank test with the same quantities of reagent used for the test specimen, and make any necessary correction. Each mL of 0.5 N hydrochloric acid is equivalent to 43.05 mg of $CH_3COCOCH_3$. Not less than 97% of $CH_3COCOCH_3$ is found.

Congealing temperature (651): between -2.0° and -5.5°.

Refractive index (831): between 1.3935 and 1.3965, at 20°.

Specific gravity (841): about 0.98.

1-Butanesulfonic Acid Sodium Salt (*Sodium 1-butanefulfonate*), $C_4H_9NaO_3S$ —**160.16** [2386-54-1]—Use a suitable grade with a content of not less than 99.0%.

1,4-Butane Sultone (*4-Hydroxybutane-1-sulfonic Acid delta-sultone*), $C_4H_8O_3S$ —**136.17** [1633-83-6]—Use a suitable grade with a content of NLT 99%.

Butanol—See *Butyl Alcohol*.

Butyl Acetate, Normal, $CH_3COO(CH_2)_3CH_3$ —**116.16** [123-86-4]—Use ACS reagent grade.

Butyl Alcohol (*1-Butanol; Normal Butyl Alcohol*), $CH_3(CH_2)_3CH_2OH$ —**74.12** [71-36-3]—Use ACS reagent grade.

Butyl Alcohol, Normal—See *Butyl Alcohol*.

Butyl Alcohol, Secondary (*2-Butanol*), $CH_3CH_2CH(OH)CH_3$ —**74.12** [78-92-2]—Use a suitable grade with a content of NLT 99%.

Butyl Alcohol, Tertiary, $(CH_3)_3COH$ —**74.12** [75-65-0]—Use ACS reagent grade *tert*-Butyl Alcohol.

Butyl Benzoate, $C_{11}H_{14}O_2$ —**178.23** [136-60-7]—Thick, oily, colorless to pale yellow liquid. Practically insoluble in water; soluble in alcohol and in ether.

Assay—When examined by gas-liquid chromatography, it shows a purity of not less than 98%. The following conditions have been found suitable for assaying it: use a 3-mm \times 1.8-m stainless steel column packed with liquid phase G4 on support S1A. Helium is the carrier gas, the injection port temperature is maintained at 180°, the column temperature is maintained at 190°, and the flame-ionization detector is maintained at 280°. The retention time is about 15 minutes.

Refractive index (831): between 1.4980 and 1.5000, at 20°.

***n*-Butyl Chloride** (*1-Chlorobutane*), C_4H_9Cl —**92.57** [109-69-3]—Clear, colorless, volatile liquid. [CAUTION—Highly flammable.] Practically insoluble in water. Miscible with alcohol and with ether. Use HPLC grade.

Butyl Ether (**n*-Dibutyl Ether*), $C_8H_{18}O$ —**130.23** [142-96-1]—Use a suitable grade.

Butyl Methacrylate, $C_8H_{14}O_2$ —**142.20** [97-88-1]—Use a suitable grade.

***tert*-Butyl Methyl Ether**, $C_5H_{12}O$ —**88.15** [1634-04-4]—Colorless liquid.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 100°; the detector temperature is maintained at 300°; and the column temperature is maintained at ambient tempera-

ture and programmed to rise 10° per minute to 150°. The area of the C₅H₁₂O peak is not less than 99.8% of the total peak area.

Refractive index (831): between 1.367 and 1.371 at 20°.

n-Butylamine, CH₃CH₂CH₂CH₂NH₂—**73.14**

[109-73-9]—Colorless to pale yellow, flammable liquid. Miscible with water, with alcohol, and with ether. Store in tight containers. Specific gravity: about 0.740.

Distilling range, Method I (721)—Not less than 95% distills between 76° and 78°.

Water, Method I (921): not more than 1.0%, determined by the *Titrimetric Method*.

Chloride (Reagent test)—One g (1.5 mL) shows not more than 0.01 mg of Cl (0.001%).

Acidic impurities—To 50 mL add 5 drops of a saturated solution of azo violet in benzene, and titrate quickly with 0.1 N sodium methoxide VS to a deep blue endpoint, observing precautions to prevent absorption of atmospheric carbon dioxide as by use of an atmosphere of nitrogen: not more than 1.0 mL of 0.1 N sodium methoxide is required for neutralization.

tert-Butylamine, C₃H₉CNH₂—**73.14** [75-64-9]—Liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm × 30-m capillary column coated with a 1-μm layer of phase G2; the injection port temperature is maintained at 230°; the detector temperature is maintained at 300°; the column temperature is maintained at 130° and programmed to rise 10° per minute to 280°. The area of the C₃H₉CNH₂ peak is not less than 99.5% of the total peak area.

Refractive index (831): between 1.3770 and 1.3790 at 20°.

4-(Butylamino)benzoic Acid, C₁₁H₅NO₂—**193.25**

[4740-24-3]—Use a suitable grade.

[NOTE—A suitable grade is available from Sigma-Aldrich, Inc., P.O. Box 2060, Milwaukee, WI 53201; www.sigma-aldrich.com.]

n-Butylboronic Acid (1-Butaneboronic Acid),

C₄H₉B(OH)₂—**101.94** [4426-47-5]—Use a suitable grade.

[NOTE—This reagent is usually shipped and stored under water. Before use, remove any excess water by light vacuum filtration. A suitable grade is available from Sigma-Aldrich, www.sigma-aldrich.com.]

tert-Butyldimethylchlorosilane in N-Methyl-N-tert-butyldimethylsilyltrifluoroacetamide, (1 in 100)—Use a suitable grade.

[NOTE—A suitable grade is available as 99% MTBSTFA, 1% TBDMCS from Regis Chemical Company, 8210 Austin Ave., P.O. Box 519, Morton Grove, IL 60053.]

4-tert-Butylphenol, C₁₀H₁₄O—**150.22** [98-54-4]—

White, crystalline flakes or needles. Practically insoluble in water; soluble in alcohol and in ether.

Melting range (741): between 98° and 101°.

t-Butylthiol (tert-Butylthiol; tert-Butyl Mercaptan; 2-Methyl-2-propanethiol; TBM), (CH₃)₃CSH—**90.19** [75-66-1]—Use a suitable grade with a content of NLT 98.0%.

[NOTE—A suitable grade is available as catalog number 20230 at www.sigma-aldrich.com.]

Butyraldehyde (Butanal), C₄H₈O—**72.11** [123-72-8]—

Use a suitable grade, purified by redistillation, with a content of not less than 99.5%.

Butyric Acid, C₄H₈O₂—**88.11** [107-92-6]—Clear, colorless to faint yellow liquid. Miscible with water and with methanol.

Assay—Weigh accurately about 500 mg, transfer to a suitable container, add 30 mL of water, and mix. Add 40 mL of water, and mix. Add phenolphthalein TS, and titrate with 0.1 N sodium hydroxide VS. Each mL of 0.1 N sodium hydroxide is equivalent to 8.81 mg of C₄H₈O₂; not less than 99.0% of C₄H₈O₂ is found.

Refractive index (831): about 1.398 at 20°.

Butyrolactone (Dihydro-2-(3H)-furanone, γ-butyrolactone)

—**86.1** [96-48-0]—Clear, colorless to practically colorless, oily liquid. Miscible with water. Soluble in methanol and in ether.

Boiling range (721): between 193° and 208°.

Refractive index (831): about 1.435, at 20°.

Specific gravity (841): between 1.128 and 1.135.

Butyrophenone (Phenyl Propyl Ketone), C₁₀H₁₂O—**148.21** [495-40-9]—Use a suitable grade with a content of not less than 98.0%.

Cadmium Acetate, C₄H₆CdO₄ · 2H₂O—**266.53**

[543-90-8]—Colorless, transparent to translucent crystals. Freely soluble in water; soluble in alcohol.

Insoluble matter (Reagent test): not more than 1 mg, from 20 g (0.005%).

Chloride (Reagent test)—One g shows not more than 0.01 mg of Cl (0.001%).

Sulfate (Reagent test, *Method II*)—Dissolve 10 g in 100 mL of water, add 1 mL of hydrochloric acid, and filter: the residue weighs not more than 1.2 mg more than the residue obtained in a complete blank test (0.005%).

Substances not precipitated by hydrogen sulfide—Dissolve 2 g in a mixture of 135 mL of water and 15 mL of 1 N sulfuric acid, heat to boiling, and pass a rapid stream of hydrogen sulfide through the solution as it cools. Filter, and to 75 mL of the clear filtrate add 0.25 mL of sulfuric acid, then evaporate to dryness, and ignite gently: the residue weighs not more than 1 mg (0.1%).

Cadmium Nitrate, Cd(NO₃)₂ · 4H₂O—**308.48**

[10325-94-7]—Colorless, hygroscopic crystals. Very soluble in water; soluble in alcohol.

Insoluble matter (Reagent test): not more than 1 mg, from 20 g (0.005%).

Chloride (Cl) (Reagent test)—One g shows not more than 0.01 mg of Cl (0.001%).

Sulfate (Reagent test, *Method II*)—Evaporate a mixture of 12 g of specimen and 25 mL of hydrochloric acid on a steam bath to dryness. Add another 15 mL of hydrochloric acid, and again evaporate to dryness. Dissolve the residue in 100 mL of water, filter, and add 1 mL of hydrochloric acid: the residue weighs not more than 1.0 mg more than the residue obtained in a blank test (0.003%).

Copper (Cu)—Dissolve 0.5 g in 10 mL of water, add 10 mL of *Ammonium Citrate Solution* (see *Lead* (251)), and adjust the reaction to a pH of about 9 by the addition of 1 N ammonium hydroxide (about 30 mL). Add 1 mL of sodium diethyldithiocarbamate solution (1 in 1000), and mix. Add 5 mL of amyl alcohol, shake for about 1 minute, and allow the layers to separate: any yellow color in the amyl alcohol layer is not darker than that of a blank to which 0.01 mg of Cu has been added (0.002%).

Iron (Fe)—Dissolve 1 g in 15 mL of water, add 2 mL of hydrochloric acid, and boil for 2 minutes. Cool, and add about 30 mg of ammonium persulfate and 15 mL of a solution of potassium thiocyanate in normal butyl alcohol (made by dissolving 10 g of potassium thiocyanate in 10 mL of water, warming the solution to about 30°, diluting with normal butyl alcohol to 100 mL, and shaking until clear). Shake vigorously for 30 seconds, and allow the layers to separate: any red color in the clear alcoholic layer is not darker than that of a blank to which 0.01 mg of Fe has been added (0.001%).

Lead (Pb)—Dissolve 1.0 g in 10 mL of water, add 0.2 mL of glacial acetic acid, and filter if necessary. To a 7-mL portion of water add 0.2 mL of glacial acetic acid and 3 mL of

Standard Lead Solution (see *Lead* <251>), and mix, to provide a blank. Then add to each solution 1.0 mL of potassium chromate solution (1 in 10), and mix: after 5 minutes, the test solution is not more turbid than the blank (0.003%).

Substances not precipitated by hydrogen sulfide—Dissolve 2 g in 145 mL of water, add 5 mL of sulfuric acid (1 in 10), heat to boiling, and pass a rapid stream of hydrogen sulfide through the solution as it cools. Filter, and to 75 mL of the clear filtrate add 0.25 mL of sulfuric acid, then evaporate to dryness, and ignite gently: the residue weighs not more than 1 mg (0.1%).

Calcium Acetate, $\text{Ca}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{H}_2\text{O}$ —**176.18** [5743-26-0]—White, crystalline granules or powder. Soluble in about 3 parts of water; slightly soluble in alcohol. Use ACS reagent grade.

Calcium Carbonate, CaCO_3 —**100.09** [471-34-1]—Use ACS reagent grade.

[NOTE—Calcium Carbonate of a quality suitable as a primary standard is available from the National Institute of Standards and Technology, Office of Standard Reference Materials, www.nist.gov, as standard sample No. 915.]

Calcium Carbonate, Chelometric Standard, CaCO_3 —**100.09** [471-34-1]—Use ACS reagent grade.

Calcium Caseinate—White or slightly yellow, nearly odorless, powder. Insoluble in cold water, but forms a milky solution when suspended in water, stirred, and heated.

Residue on ignition (Reagent test)—Ignite 5 g at 550°: the residue weighs between 150 and 300 mg (3.0% to 6.0%).

Calcium—Treat the residue from the preceding test with 10 mL of diluted hydrochloric acid, filter, and to the clear filtrate add 5 mL of ammonium oxalate TS: it shows a white precipitate upon standing.

Loss on drying <731>—Dry it in vacuum at 70° to constant weight: it loses not more than 7.0% of its weight.

Fat—Suspend 1.0 g in 5 mL of alcohol in a Mojonnier flask, add 0.8 mL of stronger ammonia water and 9 mL of water, and shake. Add a second 5-mL portion of alcohol, then add successive portions of 25 mL each of ether and solvent hexane, shaking after each addition by inverting the flask 30 times. Centrifuge, decant the solvent layer, evaporate it at a low temperature, and dry on a steam bath: the residue weighs not more than 20 mg (2.0%).

Nitrogen content, Method I <461>—Between 12.5% and 14.3% of N is found, calculated on the anhydrous basis.

Suspensibility in water—Place 2 g in a beaker, and add cool water slowly with stirring to form a thin, smooth paste. Add additional water to make a total of 100 mL. Stir, and heat to 80°: a milky suspension is formed that does not settle after standing for 2 hours.

Calcium Chloride, $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ —**147.01** [10035-04-8]—Use ACS reagent grade Calcium Chloride Dihydrate.

Calcium Chloride, Anhydrous (for drying), CaCl_2 —**110.98** [10043-52-4]—Use ACS reagent grade Calcium Chloride Desiccant.

Calcium Citrate, $\text{Ca}_3(\text{C}_6\text{H}_5\text{O}_7)_2 \cdot 4\text{H}_2\text{O}$ —**570.49** [813-94-5]—A white, crystalline powder. Slightly soluble in water; freely soluble in 3 N hydrochloric acid and in 2 N nitric acid; insoluble in alcohol. To 15 mL of hot 2 N sulfuric acid add in small portions and with stirring about 500 mg of calcium citrate. Boil the mixture for 5 minutes, and filter while hot: the cooled filtrate responds to the identification test for *Citrate* <191>.

Assay—Accurately weigh about 400 mg of the salt, previously dried at 150° to constant weight, and transfer to a 250-mL beaker. Dissolve the test specimen in 150 mL of water containing 2 mL of 3 N hydrochloric acid, add 15 mL of 1 N sodium hydroxide and 250 mg of hydroxy naphthol blue, and titrate with 0.05 M edetate disodium VS until the solution turns deep blue. Each mL of 0.05 M edetate disodium is equivalent to 8.307 mg of $\text{Ca}_3(\text{C}_6\text{H}_5\text{O}_7)_2$: between 97.5% and 101% is found.

Calcium oxide and carbonate—Triturate 1 g of calcium citrate with 5 mL of water for 1 minute: the mixture does not turn red litmus blue. Then add 5 mL of warm 3 N hydrochloric acid: only a few isolated bubbles escape.

Hydrochloric acid-insoluble matter—Dissolve 5 g by heating with a mixture of 10 mL of hydrochloric acid and 50 mL of water for 30 minutes: not more than 2.5 mg of insoluble residue remains (0.05%).

Loss on drying <731>—Dry it at 150° to constant weight: it loses between 12.2% and 13.3% of its weight.

Arsenic <211>—Proceed with 0.50 g as directed for organic compounds (6 ppm of As).

Heavy metals, Method I <231>: 0.002%.

Calcium Hydroxide [1305-62-0]—Use ACS reagent grade.

Calcium Lactate, $(\text{CH}_3\text{CHOHCOO})_2\text{Ca} \cdot 5\text{H}_2\text{O}$ —**308.29** [814-80-2]—White granules or powder. Is somewhat efflorescent and at 120° becomes anhydrous. One g dissolves in 20 mL of water; practically insoluble in alcohol. Store it in tight containers.

Assay—Accurately weigh about 500 mg, previously dried at 120° for 4 hours, transfer to a suitable container, and dissolve in 150 mL of water containing 2 mL of diluted hydrochloric acid. Add 15 mL of sodium hydroxide TS and 300 mg of hydroxy naphthol blue indicator, and titrate with 0.05 M edetate disodium VS until the solution is deep blue. Each mL of 0.05 M edetate disodium is equivalent to 10.91 mg of $\text{C}_6\text{H}_{10}\text{CaO}_6$. Not less than 98% is found.

Loss on drying <731>—Dry it at 120° for 4 hours: it loses between 25.0% and 30.0% of its weight.

Acidity—Add phenolphthalein TS to 20 mL of a 1 in 20 solution, and titrate with 0.10 N sodium hydroxide: not more than 0.50 mL is required to produce a pink color.

Heavy metals (Reagent test)—Dissolve 1 g in 2.5 mL of diluted hydrochloric acid, dilute with water to 40 mL, and add 10 mL of hydrogen sulfide TS: any brown color produced is not darker than that of a control containing 0.02 mg of added Pb (0.002%).

Magnesium and alkali salts—Mix 1 g with 40 mL of water, carefully add 5 mL of hydrochloric acid, heat the solution, boil for 1 minute, and add rapidly 40 mL of oxalic acid TS. Add immediately to the warm mixture 2 drops of methyl red TS, then add ammonia TS dropwise, from a buret, until the mixture is just alkaline. Cool to room temperature, transfer to a 100-mL graduated cylinder, dilute with water to 100 mL, mix, and allow to stand for 4 hours or overnight. Filter, and transfer to a platinum dish 50 mL of the clear filtrate, to which has been added 0.5 mL of sulfuric acid. Evaporate the mixture on a steam bath to a small bulk. Carefully heat over a free flame to dryness, and continue heating to complete decomposition and volatilization of ammonium salts. Finally ignite the residue at 800 ± 25° for 15 minutes: the residue weighs not more than 5 mg (1%).

Volatile fatty acid—Stir about 500 mg with 1 mL of sulfuric acid, and warm: the mixture does not emit an odor of volatile fatty acid.

Calcium Nitrate, $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ —**236.15** [13780-06-8]—Use ACS reagent grade.

Calcium Pantothenate, Dextro—Use *Calcium Pantothenate* (USP monograph).

Calcium Sulfate, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ —**172.17** [7778-18-9]—Use ACS reagent grade.

Calconcarboxylic Acid (2-Naphthalenecarboxylic acid, 3-hydroxy-4-[(2-hydroxy-4-sulfo-1-naphthalenyl)azo]; *Calcon-3-carboxylic Acid*; *Cal-Red*), $\text{C}_{21}\text{H}_{14}\text{N}_2\text{O}_7\text{S}$ —**438.42** [3737-95-9]—Use a suitable grade.

Calconcarboxylic Acid Triturate—Mix 1 part of calconcarboxylic acid with 99 parts of sodium chloride.

Test for sensitivity—Dissolve 50 mg of calconcarboxylic acid triturate in a mixture of 2 mL 10 N sodium hydroxide and 100 mL of water. The solution is blue but becomes violet on addition of 1 mL of a 10 g per L solution of magnesium sulfate and 0.1 mL of a 1.5 g per L solution of calcium

chloride and turns pure blue on addition of 0.15 mL of 0.01 M sodium edetate.

Calf Thymus DNA—Use a suitable grade. [NOTE—A suitable grade is commercially available from Worthington Biochemical Corp., www.worthington-biochem.com.]

dl-Camphene, $C_{10}H_{16}$ —**136.24** [79-92-5]—Use a suitable grade.

[NOTE—A suitable grade is available as camphene, 95%, catalog number 45,606-5, from Sigma-Aldrich, www.sigma-aldrich.com.]

d-10-Camphorsulfonic Acid [(1S)-(+)-10-Camphorsulfonic acid; (1S)-Camphor-10-sulfonic acid; (+)-Camphor-10-sulfonic acid (β)], $C_{10}H_{16}O_4S$ —**232.30** [3144-16-9]—Use a suitable grade.

[NOTE—A suitable grade is available as catalog number C2107 from www.sigma-aldrich.com.]

dl-10-Camphorsulfonic Acid, [Camphor-10-sulfonic acid (β)]; [(RS)-10-Camphorsulfonic acid], $C_{10}H_{16}O_4S$ —**232.30** [5872-08-2]—Is optically inactive.

Use a suitable grade.

[NOTE—A suitable grade is available as catalog number 147923 from www.sigma-aldrich.com.]

Canada Balsam [8007-47-4]—A natural product derived from the resin of *Abies balsamea*. Use a suitable grade.

Canola Oil [120962-03-0]—Use a suitable grade.

Capric Acid (Decanoic Acid), $C_{10}H_{20}O_2$ —**172.26** [334-48-5]—White, solidified melt or fragments. Soluble in alcohol, in chloroform, and in ether; practically insoluble in water.

Assay—Inject an appropriate sample dissolved in acetone into a gas chromatograph (see *Chromatography* (621)) that is equipped with a flame-ionization detector and contains a 0.53-mm × 30-m capillary column coated with a layer of phase G25. The carrier gas is helium, flowing at a rate of 9 mL per minute. The chromatograph is programmed as follows. Initially the column temperature is equilibrated at 150°, then the temperature is increased at a rate of 10° per minute to 250°. The injection port temperature is maintained at 240°, and the detector temperature at 265°. The area of the capric acid peak is not less than 98.5% of the total peak area.

Melting range (741): between 30° and 33°.

Carbazole, $C_{12}H_9N$ —**167.21** [86-74-8]—Off-white to tan powder.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm × 30-m capillary column coated with a 1-μm layer of phase G2; the injection port temperature is maintained at 280°; the detector temperature is maintained at 300°; and the column temperature is maintained at 280°. The area of the $C_{12}H_9N$ peak is not less than 95.5% of the total peak area.

Carbon Dioxide Detector Tube—A fuse-sealed glass tube so designed that gas may be passed through it. Contains suitable absorbing filters and support media for the indicators hydrazine and crystal violet.

Measuring range: 0.01 to 0.3 Vol.-%.

[NOTE—Available from Draeger Safety, Inc., www.draeger.com, or from Gastec Corp., www.gastec.co.jp, distributed in the USA by www.nextteq.com.]

Carbon Disulfide, Chromatographic—Use a suitable grade.

Carbon Disulfide, CS [75-15-0]—Use ACS reagent grade.

Carbon Monoxide Detector Tube—A fuse-sealed glass tube so designed that gas may be passed through it. Contains suitable absorbing filters and support media for the indicators iodine pentoxide and selenium dioxide and fuming sulfuric acid.

Measuring range: 5 to 150 ppm.

[NOTE—Available from Draeger Safety, Inc., www.draeger.com, or from Gastec Corp., www.gastec.co.jp, distributed in the USA by www.nextteq.com.]

Carbon Tetrachloride, CCl_4 —**153.82** [56-23-5]—Use a grade meeting the specifications of ACS *Reagent Chemicals*, 8th Edition.

Carboxylate (Sodium Form) Cation-exchange Resin (50- to 100-mesh)—See *Cation-Exchange Resin, Carboxylate (Sodium Form) (50- to 100-mesh)*.

Carboxymethoxylamine Hemihydrochloride, $2(C_2H_5NO_3) \cdot HCl$ —**218.59** [2921-14-4]—White, crystalline powder. Use a suitable grade.

Carmine (Alum Lake of Carminic Acid), $C_{22}H_{20}O_{13} \cdot xAl$ [1390-65-4]—Red powder. Use a suitable grade.

(R)-(-)-Carvone (2-Methyl-5-(1-methylethenyl)-2-cyclohexene-1-one), $C_{10}H_{14}O$ —**150.22** [6485-40-1]—Use a suitable grade.

Casein [9000-71-9]—White or slightly yellow, granular powder. Insoluble in water and in other neutral solvents; readily dissolved by ammonia TS and by solutions of alkali hydroxides, usually forming a cloudy solution.

Residue on ignition (Reagent test)—Ignite 2 g; the residue weighs not more than 20 mg (1.0%).

Loss on drying (731)—Dry it at 105° to constant weight; it loses not more than 10.0% of its weight.

Alkalinity—Shake 1 g with 20 mL of water for 10 minutes, and filter: the filtrate is not alkaline to red litmus paper.

Soluble substances—When the filtrate from the *Alkalinity* test is evaporated and dried at 105°, the residue weighs not more than 1 mg (0.1%).

Fats—Dissolve 1 g in a mixture of 10 mL of water and 5 mL of alcoholic ammonia TS, and shake out with two 20-mL portions of solvent hexane. Evaporate the hexane at a low temperature, and dry at 80°: the weight of the residue does not exceed 5 mg (0.5%).

Nitrogen content, Method I (461): between 15.2% and 16.0% of N is found, on the anhydrous basis.

Where vitamin-free casein is required, use casein that has been rendered free from the fat-soluble vitamins by continuous extraction with hot alcohol for 48 hours followed by air-drying to remove the solvent.

Casein, Hammersten [9000-71-9]. [NOTE—A suitable grade is available from www.emdchemicals.com, catalog number CX0525-1.]

Catechol (o-Dihydroxybenzene; Pyrocatechol), $C_6H_4(OH)_2$ —**110.11** [120-80-9]—White crystals, which become discolored on exposure to air and light. Readily soluble in water, in alcohol, in benzene, in ether, in chloroform, and in pyridine, forming clear solutions.

Use a suitable grade with a content of not less than 99%.

Cation-Exchange Resin—Use a suitable grade.

[NOTE—A suitable grade is available commercially as “Dowex 50-W-X8-100,” from Sigma-Aldrich, www.sigma-aldrich.com.]

Cation-Exchange Resin, Carboxylate (Sodium Form) (50- to 100-mesh)—Use a suitable grade.

[NOTE—A suitable grade is available as “Bio-Rex 70” from BioRad Laboratories, www.bio-rad.com.]

Cation-Exchange Resin, Polystyrene—Use a suitable grade.

[NOTE—A suitable grade is available as Dowex-50X2-100, from Sigma-Aldrich, www.sigma-aldrich.com.]

Cation-Exchange Resin, Styrene-Divinylbenzene—A strongly acidic, cross-linked sulfonated resin containing about 2% of divinylbenzene. It is available in the hydrogen form in the 50- to 100-, 100- to 200-, and 200- to 400-mesh sizes. It can be regenerated to the hydrogen form by treating with a hydrochloric acid solution (5 in 100). For satisfactory regeneration, a contact time of at least 30 minutes is required after which it must be washed free of excess acid. It is insoluble in water, in methanol, and in acetonitrile. Suitable for use in column chromatography.

Moisture content of fully regenerated and expanded resin—Transfer 10 to 12 mL of the resin (as received) to a flask, and convert it completely to the hydrogen form by stirring with 150 mL of hydrochloric acid solution (5 in 100) for not less than 30 minutes. Decant the acid, and wash the resin in the same manner with water until the wash water is neutral to litmus (pH 3.5).

Transfer 5 to 7 mL of the regenerated resin to a glass filtering crucible, and remove only the excess surface water by very careful suction filtration. Transfer the conditioned resin to a tared weighing bottle, and weigh. Dry in a vacuum oven at a pressure of 50 mm of mercury at 100° to 105° for 16 hours. Transfer from the vacuum oven to a desiccator, cool to room temperature, and weigh again. The loss in weight is between 75% and 83%.

Total wet volume capacity—Transfer 3 to 5 mL of the regenerated, undried (See *Moisture content* above) resin to a 5-mL graduated cylinder, and fill it with water. Remove any air bubbles from the resin bed with a stainless steel wire, and settle the resin to its minimum volume by tapping the graduated cylinder. Record the volume of the resin.

Transfer the resin to a 400-mL beaker. Add about 5 g of sodium chloride, and titrate, stirring well, with 0.1 N sodium hydroxide to the blue endpoint of bromothymol blue (pH 7.0).

$$(\text{net mL NaOH} \times N)/(\text{mL of resin}) = \text{mEq/mL}$$

The total wet volume capacity of the resin is more than 0.6 mEq per mL.

Wet screen analysis—The purpose of this test is to properly identify the mesh size of the resin. To obtain an accurate screen analysis would require a special apparatus and technique.

Add 150 mL of resin to 200 mL of water in an appropriate bottle, and allow it to stand at least 4 hours to completely swell the resin.

Transfer, by means of a graduated cylinder, 100 mL of settled and completely swollen resin to the top screen of a series of the designated U.S. Standard 20.3-cm brass screens. Thoroughly wash the resin on each screen with a stream of water until the resin is completely classified, collecting the wash water in a suitable container. Wash the beads remaining on the respective screens back into the 100-mL graduate, and record the volume of settled resin on each screen. At least 70% of the resin will be within the specific mesh size.

[NOTE—A suitable resin is Dowex 50WX2, produced by Dow Chemical Co. (www.dow.com) and also available through Sigma-Aldrich (www.sigma-aldrich.com).]

Cation-Exchange Resin, Styrene-Divinylbenzene, Strongly Acidic—Use a suitable grade.

[NOTE—A suitable grade is available commercially as "Dowex 50-W-X8-100," from Sigma-Aldrich, www.sigma-aldrich.com.]

Cation-Exchange Resin, Sulfonic Acid—Use a suitable grade.

[NOTE—A suitable grade is available commercially as "Amberlyst 15" or as "Dowex 50-W-X2" from Sigma-Aldrich, www.sigma-aldrich.com.]

Cedar Oil (for clearing microscopic sections) [8000-27-9]—A selected, distilled oil from the wood of the red cedar, *Juniperus virginiana* Linné (Fam. Pinaceae), should be used for this purpose. Refractive index: about 1.504 at 20°. For use with homogeneous immersion lenses, a specially prepared oil having a refractive index of 1.5150 ± 0.0002 at 20° is required.

Cellulose, Chromatographic—Use a suitable grade.

[NOTE—A suitable grade is available from EMD Chemicals, www.emdchemicals.com.]

Cellulose, Microcrystalline—Use Cellulose, Microcrystalline, FCC.

Cellulose Mixture, Chromatographic—Use a suitable grade.

[NOTE—A suitable grade is available commercially, in precoated plate form, with fluorescent indicator, from EMD Chemicals, www.emdchemicals.com.]

Ceric Ammonium Nitrate, $\text{Ce}(\text{NO}_3)_4 \cdot 2\text{NH}_4\text{NO}_3$ —548.22—Use ACS reagent grade.

Ceric Ammonium Sulfate, $\text{Ce}(\text{SO}_4)_2 \cdot 2(\text{NH}_4)_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ —632.55—Yellow to yellowish-orange crystals. Dissolves slowly in water, but more rapidly when mineral acids are present. Use ACS reagent grade.

Ceric Sulfate, $\text{Ce}(\text{SO}_4)_2$ with a variable amount of water—(anhydrous) 332.24 [13590-82-4]—It may also contain sulfates of other associated rare earth elements. Yellow to orange-yellow crystals or crystalline powder. Practically insoluble in cold water; slowly soluble in cold dilute mineral acids, but more readily soluble when heated with these solvents.

Assay—Weigh accurately about 800 mg, transfer to a flask, add 25 mL of water and 3 mL of sulfuric acid, and warm until dissolved. Cool, and add 60 mL of a mixture of 1 volume of phosphoric acid and 20 volumes of water. Add 25 mL of potassium iodide solution (1 in 10), insert the stopper in the flask, and allow to stand for 15 minutes. Replace the air over the solution with carbon dioxide, and while continuing the flow of carbon dioxide into the flask, titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. Each mL of 0.1 N sodium thiosulfate is equivalent to 33.22 mg of $\text{Ce}(\text{SO}_4)_2$. Not less than 80.0% is found.

Chloride (Reagent test)—Dissolve 1 g in a mixture of 5 mL of nitric acid and 4 mL of water. Filter, if necessary, and dilute with water to 20 mL. To 10 mL of the dilution add 1 mL of silver nitrate TS, allow to stand for 10 minutes, and filter until clear. To the remaining 10 mL of test solution add 1 mL of silver nitrate TS: any turbidity produced does not exceed that in a control prepared by adding 0.05 mg of Cl to the filtrate obtained from the first 10 mL of test solution (0.01%).

Heavy metals—Heat 500 mg with a mixture of 10 mL of water and 0.5 mL of sulfuric acid until solution is complete. Cool, dilute with water to 50 mL, and bubble hydrogen sulfide gas through the solution until it is saturated: the precipitate that is formed is white or not darker than pale yellow.

Iron—Dissolve 100 mg in a mixture of 5 mL of water and 2 mL of hydrochloric acid, warming if necessary, and cool. Transfer to a glass-stoppered cylinder, dilute with water to 25 mL, and add 5 mL of ammonium thiocyanate TS and 25 mL of ether. Shake gently, but well, and allow the layers to separate: any pink color in the ether layer is not darker than that of a control, similarly prepared, containing 0.02 mg of added Fe (0.02%).

Cesium Chloride, CsCl —168.36 [7647-17-8]—A white powder. Very soluble in water; freely soluble in methanol; practically insoluble in acetone. Use a suitable grade.

Cetrimide—See *Cetyltrimethylammonium Bromide*.

Cetyltrimethylammonium Bromide (CTAB; *Cetrimide*; *Hexadecyltrimethylammonium Bromide*), $\text{C}_{19}\text{H}_{42}\text{BrN}$ —364.46 [57-09-0]—Use a suitable grade. For any chromatographic application, use a suitable grade with a content of not less than 99.0%.

Cetyltrimethylammonium Chloride, 25 Percent in Water, $\text{C}_{19}\text{H}_{42}\text{ClN}$ —320.00—Use a suitable grade.

Charcoal, Activated (*Activated Carbon*; *Decolorizing Carbon*) C—12.01 [7440-44-0]—A fine, black powder, which is the residue from the destructive distillation of various organic materials, treated to increase its high capacity for adsorbing organic coloring substances, as well as nitrogenous bases. Use *Activated Charcoal* (USP monograph).

Chenodeoxycholic Acid, $\text{C}_{24}\text{H}_{40}\text{O}_4$ —392.57 [474-25-9]—White to off-white powder.

Assay—When tested by thin-layer chromatography, with the use of plates coated with chromatographic reversed-phase C18 mixture, a developing system consisting of 1 N acetic acid in methanol and 1 N acetic acid (19:1), and sprayed with a mixture of sulfuric acid and methanol (1:1),

heated at 110° for 20 minutes, and examined visually and under long-wavelength UV light, a single spot is exhibited.

Melting range (741): between 165° and 168°.

Chloramine T (*Sodium p-Toluenesulfonchloramide*), $C_7H_7ClNNaO_2S \cdot 3H_2O$ —**281.69** [7080-50-4]—Use ACS reagent grade.

Chlorine, Cl_2 —**70.9** [7782-50-5]—Greenish-yellow gas. High-purity grade available from most suppliers of specialty gases.

Chlorine Detector Tube—A fuse-sealed glass tube so designed that gas may be passed through it and containing suitable absorbing filters and support media for the indicator o-tolidine.

Measuring range: 0.2 to 3 ppm.

[NOTE—Available from Draeger Safety, Inc., www.draeger.com, or from Gastec Corp., www.gastec.co.jp, distributed in the USA by www.nextteq.com.]

m-Chloroacetanilide, C_8H_8ClNO —**169.61**—Off-white to beige granules.

Assay—

MOBILE PHASE—Prepare a mixture of acetonitrile and water (22:3).

PROCEDURE—Inject about 20 μ L into a suitable liquid chromatograph (see *Chromatography* (621)) equipped with a 254-nm detector and a 4.6-mm \times 15-cm column that contains packing L1. The flow rate is about 1.5 mL per minute. The area of the C_8H_8ClNO peak is not less than 99.9% of the total peak area.

Melting range (741): between 79° and 80°.

p-Chloroacetanilide, C_8H_8ClNO —**169.61**—White or pale yellow, needle-shaped crystals or crystalline powder. Insoluble in water; soluble in alcohol and in ether.

Solubility—One g dissolves in 30 mL of alcohol to form a clear solution.

Melting range (741): between 178° and 181°.

Residue on ignition (Reagent test): not more than 0.1%.

1-Chloroadamantane, $C_{10}H_{15}Cl$ —**170.68** [935-56-8]—White crystalline solid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 250°; the detector temperature is maintained at 300°; and the column temperature is maintained at 150° and programmed to rise 10° per minute to 280°. The area of the $C_{10}H_{15}Cl$ peak is not less than 97.5% of the total peak area.

2-Chloro-4-aminobenzoic Acid—See *4-Amino-2-chlorobenzoic Acid*.

5-Chloro-2-aminobenzophenone—See *2-Amino-5-chlorobenzophenone*.

3-Chloroaniline, C_6H_6ClN —**127.57** [108-42-9]—Colorless to light brown liquid. Soluble in acid and in most organic solvents; practically insoluble in water.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 250°; the detector temperature is maintained at 300°; and the column temperature is maintained at 150° and programmed to rise 10° per minute to 280°. The area of the C_6H_6ClN peak is not less than 99% of the total peak area.

Refractive index (831): between 1.592 and 1.596 at 20°.

p-Chloroaniline, (*4-Chloroaniline*), C_6H_6ClN —**127.57** [106-47-8]—Use a suitable grade.

Chlorobenzene, C_6H_5Cl —**112.56** [108-90-7]—Clear, colorless liquid. Insoluble in water; soluble in alcohol, in

benzene, in chloroform, and in ether. Use ACS reagent grade.

4-Chlorobenzoic Acid, C_6H_4COOH —**156.57** [74-11-3]—White, crystalline solid.

Assay—Dissolve about 700 mg, accurately weighed, in a mixture of 100 mL of hot alcohol and 50 mL of water. Titrate with 0.5 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.5 N sodium hydroxide is equivalent to 78.28 mg of C_6H_4COOH . Not less than 98% is found.

Solubility—One g dissolved in 25 mL of 0.5 N sodium hydroxide yields a clear and complete solution.

m-Chlorobenzoic Acid (*3-Chlorobenzoic Acid*), $C_7H_5ClO_2$ —**156.57** [535-80-8]—Use a suitable grade.

4-Chlorobenzophenone, $C_{13}H_9ClO$ —**216.66** [134-85-0]—Use a suitable grade.

1-Chlorobutane—See *n-Butyl Chloride*.

2-Chloroethanol (*Ethylene Chlorohydrin*), C_2H_5ClO —**80.51** [107-07-3]—Use a suitable grade with a content of NLT 99%.

2-Chloroethylamine Monohydrochloride, $C_2H_6ClN \cdot HCl$ —**115.99**—Off-white powder.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of a phase consisting of 14% cyanopropylphenyl-86% dimethylpolysiloxane; the injection port temperature is maintained at 150°; the detector temperature is maintained at 300°; and the column temperature is maintained at 50° and programmed to rise 10° per minute to 200°. The area of the $C_2H_6ClN \cdot HCl$ peak is not less than 99% of the total peak area.

Melting range (741): between 150° and 246°.

Chloroform, $CHCl_3$ —**119.38** [67-66-3]—Use ACS reagent grade.

Chloroform, Alcohol-Free—Use a suitable grade that does not contain alcohol as a stabilizer.

Chloroform, Methyl—See *Methyl Chloroform*.

Chlorogenic Acid, $C_{16}H_{18}O_9$ —**354.31** [327-97-9]—White to off-white powder. Use a suitable grade.

Assay—When tested by thin-layer chromatography (see *Chromatography* (621)) with the use of plates coated with chromatographic silica gel mixture and a developing system consisting of a mixture of butyl alcohol, water, and acetic acid (60:25:15), and examined under short-wavelength UV light, a single spot is exhibited, with trace impurities.

Chloromethylated Polystyrene-Divinylbenzene Anion-exchange Resin—See *Anion-exchange Resin, Chloromethylated Polystyrene-Divinylbenzene*.

1-Chloronaphthalene (α -*Chloronaphthalene*), $C_{10}H_7Cl$ —**162.62** [90-13-1]—Colorless to light yellow liquid.

Assay—Use a gas chromatograph equipped with a flame-ionization detector. The following conditions have been found suitable: a 3.2-mm \times 1.83-m stainless steel column is packed with 7% phase G2 on support S1A; the injection port temperature is maintained at 250° and the detector temperature at 310°; and the column temperature is programmed to increase at a rate of 10° per minute from 50° to 250°. Not less than 90% of $C_{10}H_7Cl$ is found, of which not more than 10% is 2-chloronaphthalene.

Refractive index (831): between 1.6320 and 1.6340, at 20°.

4-Chloro-1-naphthol, $C_{10}H_7ClO$ —**178.6** [604-44-4]—A white to off-white powder, with a melting point between 118° and 120°. Use a suitable grade. Store below 0°.

2-Chloronicotinic Acid, $C_6H_4ClNO_2$ —**157.55** [2942-59-8]—Off-white powder.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas.

The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 280°; the detector temperature is maintained at 300°; and the column temperature is maintained at 180° and programmed to rise 10° per minute to 280°. The area of the $C_6H_4ClNO_2$ peak is not less than 98% of the total peak area.

2-Chloro-4-nitroaniline, 99%, $C_6H_5ClN_2O_2$ —**172.57**
[121-87-9]—White to off-white powder.

Melting range (741): between 107° and 109°.

Chloroplatinic Acid, $H_2PtCl_6 \cdot 6H_2O$ —**517.90**
[18497-13-7]—Use ACS reagent grade Chloroplatinic Acid Hexahydrate.

5-Chlorosalicylic Acid, $C_7H_5ClO_3$ —**172.57**
[321-14-2]—White to off-white powder.

Assay—When tested by thin-layer chromatography (see *Chromatography* (621)) with the use of plates coated with chromatographic silica gel mixture and a developing system consisting of a mixture of cyclohexane, chloroform, and acetic acid (14:4:2), and examined visually and under long-wavelength UV light or iodine spray, a single spot is exhibited.

Melting range (741): between 172° and 178°.

1-Chloro-2,2,2-trifluoroethylchlorodifluoromethyl Ether—Use a suitable grade.

Chlorotrimethylsilane (*Trimethylsilyl Chloride*), C_3H_9ClSi —**108.64** [75-77-4]—Clear, colorless to light yellow liquid. Fumes when exposed to moist air.

[CAUTION]—It reacts vigorously with water, alcohols, and other hydrogen donors. Store in tight glass containers.]

Refractive index (831): between 1.3850 and 1.3890 at 20°.

Chlortetracycline Hydrochloride—Use *Chlortetracycline Hydrochloride* (USP monograph).

Cholestane, $C_{27}H_{48}$ —**372.67** [481-21-0]—Use a suitable grade.

Cholesterol, $C_{27}H_{46}O$ —**386.66** [57-88-5]—Use a suitable grade (*NF* monograph).

Cholesteryl Benzoate, $C_{34}H_{50}O_2$ —**490.76** [604-32-0]—Use a suitable grade.

Cholesteryl *n*-Heptylate—Use a suitable grade.

Choline Chloride, $HOCH_2CH_2N(CH_3)_3Cl$ —**139.62**
[67-48-1]—White crystals or crystalline powder. Very soluble in water. Is hygroscopic. Store in tight containers.

Assay—Transfer about 100 mg, previously dried at 105° for 2 hours and accurately weighed, to a beaker, add 20 mL of water and 1 drop of aluminum chloride solution (1 in 10), and mix. Add slowly 20 mL of a freshly prepared, filtered sodium tetraphenylborate solution (1 in 50), and allow the mixture to stand for 30 minutes with occasional swirling. Pass through a medium-porosity, sintered-glass filter, and wash the beaker and the precipitate with four 10-mL portions of water. The weight of the precipitate, determined after drying at 105° for 2 hours, and multiplied by 0.3298, gives the equivalent weight of $C_5H_{14}ClNO$. Not less than 99.5% is found.

Residue on ignition (281): not more than 0.1%.

Chromatographic Fuller's Earth—See *Fuller's Earth, Chromatographic*.

Chromatographic *n*-Heptane—See *n-Heptane, Chromatographic*.

Chromatographic Magnesium Oxide—See *Magnesium Oxide, Chromatographic*.

Chromatographic Reagents—See *Reagents, Chromatographic Reagents*.

[NOTE—Listings of the numerical designations for phases (G), packings (L), and supports (S), together with corre-

sponding brand names, are published periodically in *Pharmacopeial Forum* as a guide for the chromatographer.]

Chromatographic Silica Gel—See *Silica Gel, Chromatographic*.

Chromatographic Silica Gel Mixture—See *Silica Gel Mixture, Chromatographic*.

Chromatographic Siliceous Earth—See *Siliceous Earth, Chromatographic*.

Chromatographic Siliceous Earth, Silanized—See *Siliceous Earth, Chromatographic, Silanized*.

Chromatographic Solvent Hexane—See *Hexane, Solvent, Chromatographic*.

Chromium Potassium Sulfate Dodecahydrate, $CrK(SO_4)_2 \cdot 12H_2O$ —**499.40** [10279-63-7]—Use ACS reagent grade.

Chromium Trioxide, CrO_3 —**99.99** [1333-82-0]—Use ACS reagent grade.

Chromogenic Substrate for Amidolytic Test—Synthetic molecules consisting of tripeptides or tetrapeptides coupled to a chromophore. The terminal amino acid is specific for the protease utilized. The synthetic peptides mimic the peptide sequence (specific to the activated coagulation factor) of the active site on the natural substrate. The coagulation factor catalyzes the splitting of the chromophore (*p*-nitroaniline) from the peptide. The amount of release can be measured directly in a spectrophotometer, because the maximum absorbance spectra of the bound and free chromophores differ. The released chromophore is a colored compound; the complete substrate itself is colorless.

Molecular weights of the various substrates range from about 600 to 750 Da. Solubility in aqueous solutions can vary. Not all substrates are of equal sensitivity, and incubation periods may have to be extended.

Chromotrope 2R, $C_{16}H_{10}N_2Na_2O_8S_2$ —**468.4**
[4197-07-3]—Red powder or crystals. Use a suitable grade.

Chromotropic Acid (4,5-Dihydroxy-2,7-naphthalenedisulfonic Acid), $C_{10}H_8O_8S_2 \cdot 2H_2O$ —**356.33**
[148-25-4], for the anhydrous form—Use a suitable grade.

Chromotropic Acid Disodium Salt (4,5-Dihydroxy-2,7-naphthalenedisulfonic Acid, Disodium Salt), $C_{10}H_6O_8Na_2S_2 \cdot 2H_2O$ —**400.29** [5808-22-0]—Use ACS reagent grade.

Cinchonidine, $C_{19}H_{22}N_2O$ —**294.39** [485-71-2]—White crystals, crystalline or granular powder. Soluble in alcohol and in chloroform; practically insoluble in water.

Assay—Dissolve about 125 mg, accurately weighed, in 50 mL of glacial acetic acid. Add a few drops of *p*-naphtholbenzein TS, and titrate with 0.1 N perchloric acid VS. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N perchloric acid is equivalent to 14.72 mg of $C_{19}H_{22}N_2O$. Not less than 99.0% is found.

Loss on drying (731)—Dry it at 105° to constant weight; it loses not more than 1.0% of its weight.

Melting range (741): between 200° and 205°.

Specific rotation (781): between −105° and −115°, calculated on the dried basis, determined in a solution in alcohol containing 10 mg per mL.

Cinchonine, $C_{19}H_{22}N_2O$ —**294.39** [118-10-5]—White crystals, crystalline or granular powder. Slightly soluble in chloroform, sparingly soluble in alcohol, and practically insoluble in water.

Assay—Dissolve about 125 mg, accurately weighed, in 50 mL of glacial acetic acid. Add a few drops of *p*-naphtholbenzein TS, and titrate with 0.1 N perchloric acid VS. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N perchloric acid is equivalent to 14.72 mg of $C_{19}H_{22}N_2O$. Not less than 99.0% is found.

Loss on drying (731)—Dry it at 105° to constant weight; it loses not more than 1.0% of its weight.

Melting range (741): between 255° and 261°.

Specific rotation (781): between +219° and +229°, calculated on the dried basis, determined in a solution in alcohol containing 50 mg per 10 mL.

Citric Acid—Use *Citric Acid Monohydrate* (USP monograph).

Citric Acid, Anhydrous [77-92-9]—Use *Anhydrous Citric Acid* (USP monograph).

Cobalt Chloride (*Cobaltous Chloride*), $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ —**237.93** [7791-13-1]—Use ACS reagent grade.

Cobalt Nitrate, $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ —**291.03**

[10026-22-9]—Use ACS reagent grade.

Cobaltous Acetate (*Cobalt Acetate*), $\text{Co}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 4\text{H}_2\text{O}$ —**249.08** [71-48-7]—Red, needlelike crystals. Soluble in water and in alcohol. Use ACS reagent grade.

Cobaltous Chloride—See *Cobalt Chloride*.

Coenzyme Q9 (*Ubiquinone 45*), $\text{C}_{54}\text{H}_{82}\text{O}_4$ —**795.2** [303-97-9]—Yellow to yellow-orange powder. Clear yellow solution, at a concentration of 1 mg per mL in a mixture of chloroform and ethanol (9:1).

Absorptivity—Its absorptivity at 275 nm, in alcohol solution, is about 1700.

Collagen—Use a suitable grade.

[NOTE—A suitable grade is acid-soluble Collagen Type I from calf skin, and is commercially available from Sigma-Aldrich Corp., www.sigma-aldrich.com; catalog number C3511.]

Rat Tail Collagen—Use a suitable grade.

[NOTE—A suitable grade is available from BD Biosciences, www.bdbiosciences.com.]

Collagenase—Use a suitable grade.

[NOTE—A suitable grade is commercially available as Collagenase Type 2, CLS-2, from Worthington Biochemical Corp., www.worthington-biochem.com.]

Compactin, $\text{C}_{23}\text{H}_{34}\text{O}_5$ —**390.52** [73573-88-3]—Use a suitable grade.

[NOTE—A suitable grade is available from Sigma-Aldrich, www.sigma-aldrich.com.]

Congo Red, $\text{C}_{32}\text{H}_{22}\text{N}_6\text{Na}_2\text{O}_6\text{S}_2$ —**696.67** [573-58-0]—A dark red or reddish-brown powder. Decomposes on exposure to acid fumes. Its solutions have a pH of about 8 to 9.5. One g dissolves in about 30 mL of water. Is slightly soluble in alcohol.

Loss on drying (731)—Dry it at 105° for 4 hours: it loses not more than 3.0% of its weight.

Residue on ignition—Accurately weigh about 1 g, previously dried at 105° for 4 hours, and place it in a porcelain dish or crucible. Carefully ignite until well charred, cool, add 2 mL of sulfuric acid, and carefully ignite until the residue is white or practically so. Cool, add 0.5 mL of sulfuric acid and 1 mL of nitric acid, evaporate, and again ignite to constant weight: the weight of the sodium sulfate so obtained is between 20.0% and 24.0% of the weight of the dried specimen taken.

Sensitiveness—To 50 mL of carbon dioxide-free water add 0.1 mL of congo red solution (1 in 1000). The red color of the solution is changed to violet by the addition of 0.05 mL of 0.10 N hydrochloric acid and is restored by the subsequent addition of 0.05 mL of 0.10 N sodium hydroxide.

Coomassie Blue G-250 (*Coomassie Brilliant Blue G-250*, *Serva Blue G*), $\text{C}_{47}\text{H}_{48}\text{N}_3\text{O}_7\text{S}_2\text{Na}$ —**854.0** [6104-58-1]—A dark blue powder. Soluble in water. Use a suitable grade. Store between 15° and 30°.

Coomassie Brilliant Blue R-250, $\text{C}_{45}\text{H}_{44}\text{N}_3\text{O}_7\text{S}_2\text{Na}$ —**825.97** [6104-58-1]—Brown powder.

Copper, Cu—**At. Wt. 63.546** [7440-50-8]—Use ACS reagent grade.

Cortisone, $\text{C}_{21}\text{H}_{28}\text{O}_5$ —**360.44** [53-06-5]—White, crystalline powder. Practically insoluble in water; sparingly solu-

ble in alcohol and in acetone. Melts at about 220°, with decomposition.

Absorption maximum—The UV absorption spectrum of a 1 in 100,000 solution in alcohol shows a maximum at about 238 nm.

Specific rotation (781): about +209°, determined in a 1 in 100 solution in alcohol.

Cotton, Absorbent—Use *Purified Cotton* (USP monograph).

m-Cresol Purple, $\text{C}_{21}\text{H}_{18}\text{O}_5\text{S}$ —**382.43** [2303-01-7]—Use a suitable grade.

Cupric Acetate, $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{H}_2\text{O}$ —**199.65** [6046-93-1]—Use ACS reagent grade.

Cupric Chloride, $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ —**170.48** [7447-39-4]—Bluish-green deliquescent crystals. Freely soluble in water; soluble in alcohol; slightly soluble in ether. Use ACS reagent grade.

Cupric Citrate (*[Citrate(4-)]dicopper*), $\text{Cu}_2\text{C}_6\text{H}_4\text{O}_7$ —**315.18** [866-82-0]—Use a suitable grade.

Cupric Nitrate [3251-23-8]—Use ACS reagent grade *Cupric Nitrate Hydrate*.

Cupric Nitrate Hydrate, $\text{Cu}(\text{NO}_3)_2 \cdot 2.5\text{H}_2\text{O}$ —**232.59** [3252-23-8]; $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$ —**241.60** [10031-43-3]—Use ACS reagent grade.

[NOTE—This reagent is available containing either 2.5 or 3 molecules of water of hydration.]

Cupric Sulfate, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ —**249.69**—Use ACS reagent grade.

Cupric Sulfate, Anhydrous, CuSO_4 —**159.61**

[7758-98-7]—A white or grayish-white powder free from a blue tinge. Upon the addition of a small quantity of water, it becomes blue. Soluble in water. Store in tight containers.

Chloride (Reagent test)—One g shows not more than 0.02 mg of Cl (0.002%).

Substances not precipitated by hydrogen sulfide—Determine as directed for ACS reagent grade of *Cupric Acetate*: the residue weighs not more than 6 mg (0.15%).

Cupriethylenediamine Hydroxide Solution, 1.0 M—Use a suitable grade.

[NOTE—A suitable grade is available from GFS Chemicals, www.gfschemicals.com.]

Cyanoacetic Acid, $\text{C}_3\text{H}_3\text{NO}_2$ —**85.06** [372-09-8]—White to light yellow, crystalline solid. Very soluble in water.

Assay—Dissolve about 300 mg, accurately weighed, in 25 mL of water and 25 mL of alcohol. Titrate with 0.1 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination and make any necessary corrections. Each mL of 0.1 N sodium hydroxide is equivalent to 85.06 mg of $\text{C}_3\text{H}_3\text{NO}_2$. Not less than 99% is found.

Cyanogen Bromide, BrCN—**105.92** [506-68-3]—Colorless crystals. Volatilizes at room temperature. Its vapors are highly irritating and very toxic. Melts at about 52°. Freely soluble in water and in alcohol. Store in tight containers in a cold place.

Solubility—Separate 1-g portions dissolve completely in 10 mL of water and in 10 mL of alcohol, respectively, to yield colorless solutions.

4-Cyanophenol (*4-Hydroxybenzonitrile*), $\text{C}_6\text{H}_4\text{CNOH}$ —**119.12** [767-00-0]—Use 95 percent reagent.

Cyclam (*1,4,8,11-Tetraazacyclotetradecane*), $\text{C}_{10}\text{H}_{24}\text{N}_4$ —**200.33** [295-37-4]—Use 98 percent reagent.

α -Cyclodextrin (*Cyclomaltose*; *Schardinger α -Dextrin*), $\text{C}_{36}\text{H}_{60}\text{O}_{30}$ —**972.86** [10016-20-3]—Use a suitable grade with a content of not less than 98.0%.

[NOTE—A suitable grade is available from Fluka, www.sigma-aldrich.com, catalog number 28705.]

Add the following:

▲ **β-Cyclodextrin** (*β-Schardinger dextrin*; *Cycloheptaamylose*), $C_{42}H_{70}O_{35} \cdot xH_2O$ —**1134.98** (anhydrous) [68168-23-0]—Use a suitable hydrate grade.▲ *USP36*
Cyclohexane, C_6H_{12} —**84.16** [110-82-7]—Use ACS reagent grade.

Cyclohexanol, $C_6H_{12}O$ —**100.16** [108-93-0]—A clear liquid. Freely soluble in water. Miscible with alcohol, with ethyl acetate, and with aromatic hydrocarbons.

Assay—When examined by gas-liquid chromatography, using suitable gas chromatographic apparatus and conditions, it shows a purity of not less than 98%.

Melting temperature: about 23°.

Specific gravity: about 0.962, at 20°.

(1,2-Cyclohexylenedinitrilo)tetraacetic Acid (*trans*-1,2-Diaminocyclohexane-*N,N,N',N'*-tetraacetic Acid), $C_{14}H_{22}N_2O_8 \cdot H_2O$ —**364.35**—Use ACS reagent grade.

Cyclohexylmethanol, $C_7H_{14}O$ —**114.19**—Use a suitable grade.

L-Cystine, $HOOC(NH_2)CHCH_2S-SCH_2CH(NH_2)COOH$ —**240.30** [58-89-3]—A white, crystalline powder. Very slightly soluble in water; soluble in dilute mineral acids and in solutions of alkali hydroxides; insoluble in alcohol and in other organic solvents.

Specific rotation (781): between -215° and -225°, determined in a 2 in 100 solution of test specimen, previously dried over silica gel for 4 hours, in dilute hydrochloric acid (1 in 10) at a temperature of 20°.

Loss on drying (731)—Dry it over silica gel for 4 hours: it loses not more than 0.2% of its weight.

Residue on ignition (Reagent test): not more than 0.1%.

DEAE-Agarose [57407-08-6]—Agarose beads chemically bonded with diethylaminoethane and suspended in a 20% ethanol solution in water.

[NOTE—Commercially available as DEAE-Sephrose.]

Decanol (*n-Decyl Alcohol*), $C_{10}H_{22}O$ —**158.28** [112-30-1]—A clear, viscous liquid. *Specific gravity*: about 0.83 at 20°. Solidifies at about 6.5°. Insoluble in water; soluble in alcohol and in ether.

Assay—When examined by gas-liquid chromatography, using suitable gas chromatographic apparatus and conditions, it shows a purity of not less than 99%.

Decyl Sodium Sulfate, $C_{10}H_{21}NaO_4S$ —**260.33**—White, crystalline solid.

Assay—Transfer about 1 g, accurately weighed, to a suitable, tared crucible, moisten with a few drops of sulfuric acid, and ignite gently to constant weight. Each mg of residue is equivalent to 3.662 mg of $C_{10}H_{21}NaO_4S$. Not less than 95% is found.

Dehydrated Alcohol—See *Alcohol, Dehydrated*.

Deoxyadenosine Triphosphate, $C_{10}H_{16}N_5O_{12}P_3$ —**491.18** [1927-31-7]—Use a suitable grade.

[NOTE—A suitable grade is available from either BD Biosciences, www.bdbiosciences.com or Applied Biosystems, www.appliedbiosystems.com.]

Deoxycytidine Triphosphate, $C_9H_{16}N_3O_{13}P_3$ —**467.16** [2056-98-6]—Use a suitable grade.

[NOTE—A suitable grade is available from either BD Biosciences, www.bdbiosciences.com or Applied Biosystems, www.appliedbiosystems.com.]

Deoxyguanosine Triphosphate, $C_{10}H_{16}N_5O_{13}P_3$ —**507.18** [2564-35-4]—Use a suitable grade.

[NOTE—A suitable grade is available from either BD Biosciences, www.bdbiosciences.com, or Applied Biosystems, www.appliedbiosystems.com.]

Deoxyribonucleic Acid Polymerase—Thermostable, recombinant DNA polymerase. Use a suitable grade.

[NOTE—A suitable grade is available from Applied Biosystems, www.appliedbiosystems.com.]

Deoxythymidine Triphosphate, $C_{10}H_{17}N_2O_{14}P_3$ —**482.17**—Use a suitable grade.

[NOTE—A suitable grade is available from either BD Biosciences, www.bdbiosciences.com or Applied Biosystems, www.appliedbiosystems.com.]

Deuterated Methanol (*Methanol- ^{12}C - d_4* , *Methyl- ^{12}C - d_3 alcohol- d_1*)—**36.1** [811-98-3]—The degree of deuteration is not less than 99.8%. Is a clear colorless liquid miscible with water, with alcohol, and with methylene chloride; density at 20°: 0.888 g/mL; refractive index at 20° (D-line): 1.326; boiling point 65.4° (760 mm Hg).

Deuterated Water—See *Deuterium Oxide*.

Deuterium Chloride (*Deutero Hydrochloric Acid*), DCl—**37.47** [7698-05-7]—Toxic gas. Use a suitable grade with a degree of deuteration of NLT 99%.

Deuterium Oxide, D_2O —**20.032** [7789-20-0]—Use a suitable grade having a minimum isotopic purity of 99.8 atom % of deuterium.

Deuteriochloroform, $CDCl_3$ —**120.38**—Use a suitable grade.

Devarda's Alloy (*Devarda's Metal*) [8049-11-4]—A gray powder composed of 50 parts of copper, 45 parts of aluminum, and 5 parts of zinc.

Dextran, High Molecular Weight [9004-54-0]—A dextran molecular weight standard having a weight-average molecular weight, M_w , of 1 to 2×10^6 Da and a weight-average molecular weight to number-average molecular weight ratio, M_w / M_n , of 1.0 to 1.8.

[NOTE—A suitable grade is available from American Polymer Standards Corporation, www.ampolymer.com.]

Dextrin, $(C_6H_{10}O_5)_n \cdot xH_2O$ [9004-53-9]—A white amorphous powder. Slowly soluble in cold water; more readily soluble in hot water; insoluble in alcohol.

Insoluble matter—Boil 1 g with 30 mL of water in a small flask: the solution is colorless and clear, or not more than opalescent.

Loss on drying (731)—Dry it at 105° to constant weight: it loses not more than 10.0% of its weight.

Residue on ignition (Reagent test)—Ignite 1 g with 0.5 mL of sulfuric acid: the residue weighs not more than 5 mg (0.5%).

Chloride (Reagent test)—Dissolve 3 g in 75 mL of boiling water, cool, dilute with water to 75 mL, and filter if necessary. To 25 mL of the filtrate add 2 mL of nitric acid and 1 mL of silver nitrate TS, and allow to stand for 5 minutes: any turbidity produced is not greater than that of a control containing 0.02 mg of added Cl (0.002%).

Sulfate (Reagent test, *Method I*)—To a 25-mL portion of the filtrate from the preceding test add 0.5 mL of diluted hydrochloric acid and 2 mL of barium chloride TS, and allow to stand for 10 minutes: any turbidity produced is not greater than that of a control containing 0.2 mg of added SO_4 (0.02%).

Alcohol-soluble substances—Boil 1 g with 20 mL of alcohol for 5 minutes under a reflux condenser, and filter while hot. Evaporate 10 mL of the filtrate on a steam bath, and dry at 105°: the residue weighs not more than 5 mg (1%).

Reducing sugars—Shake 2 g with 100 mL of water for 10 minutes, and filter until clear. To 50 mL of the filtrate add 50 mL of alkaline cupric tartrate TS, and boil for 3 minutes. Filter through a tared filtering crucible, wash with water, then with alcohol, and finally with ether, and dry at 105° for 2 hours: the precipitate of cuprous oxide weighs not more than 115 mg (corresponding to about 5% of reducing sugars as dextrose).

Dextro Calcium Pantothenate—Use *Calcium Pantothenate* (USP monograph).

Dextrose, Anhydrous, $C_6H_{12}O_6$ —**180.16**—Use ACS reagent grade D-Glucose, Anhydrous.

Diacetyl—See *2,3-Butanedione*.

3,3'-Diaminobenzidine Hydrochloride, $(NH_2)_2C_6H_3C_6H_3(NH_2)_2 \cdot 4HCl$ —**360.11** [7411-49-6]—White to yellowish-tan (occasionally purple), needle-shaped crystals. Soluble in water. Stable in organic solvents but un-

stable in aqueous solution at room temperature. Store aqueous solutions in a refrigerator.

Insoluble matter—Dissolve 2 g in 100 mL of water, without heating, and filter immediately: the insoluble residue does not exceed 1 mg (0.05%).

Residue on ignition (Reagent test): not more than 1 mg, from 2 g (0.05%).

Suitability test for detection of selenium—Dissolve 1.633 g of selenious acid (H_2SeO_3) in water, and dilute with water to 1 L. Dilute 10 mL of this solution with water to 1 L, to make a solution containing 0.010 mg of Se per mL. Place 1 mL of the resulting solution in a 100-mL beaker, add 2 mL of formic acid solution (1 in 7), and dilute with water to 50 mL. Add 2 mL of 3,3'-diaminobenzidine hydrochloride solution (1 in 200), and allow to stand for 30 to 50 minutes. Adjust with 6 N ammonium hydroxide to a pH between 6 and 7. Transfer to a 125-mL separator, add 10.0 mL of toluene, and shake vigorously for 30 seconds: a distinct yellow color is produced in the toluene layer. A blank containing diaminobenzidine hydrochloride but no selenium standard, treated in the same manner, shows no color in the toluene layer.

2,3-Diaminonaphthalene, $\text{C}_{10}\text{H}_{10}\text{N}_2$ —**158.20** [771-97-1]—Use a suitable grade.

Diatomaceous Earth [91053-39-3]—Use a suitable grade. [NOTE—A suitable grade is available as Celite 545-AW.]

Diatomaceous Earth, Flux-Calcined [91053-39-3]—Use a suitable grade.

[NOTE—A suitable grade is "Chromosorb W, AW-DMCS," available from Grace, www.grace.com.]

Diatomaceous Earth, Silanized [91053-39-3]—Use a suitable grade.

[NOTE—Suitable grades are available commercially as "Anachrome Q," "Gas-Chrom Q," and "Varaport 30."]

Diatomaceous Silica, Calcined [68855-54-9]—A form of silica (SiO_2) consisting of fused frustules and fragments of diatoms. It is an amorphous, fine, light pink or white powder. Insoluble in water, in acids, and in dilute solutions of alkali hydroxides.

Loss on ignition—Accurately weigh about 4 g, and ignite to constant weight: it loses not more than 10.0% of its weight.

Organic impurities—It does not darken appreciably upon ignition.

Loss on drying (731)—Dry it at 110° for 2 hours: it loses not more than 2.0% of its weight.

[NOTE—Suitable grades are "Chromosorb P" and "Chromosorb W," available from Grace, www.grace.com.]

Diaveridine (5-([3,4-Dimethoxyphenyl]methyl)-2,4-pyrimidinediamine), $\text{C}_{13}\text{H}_{16}\text{N}_4\text{O}_2$ —**260.3** [5355-16-8]—Use a suitable grade. [NOTE—A suitable grade is available as catalog number 46174 from www.sigma-aldrich.com.]

Dibasic Ammonium Citrate—See *Ammonium Citrate, Dibasic*.

Dibasic Ammonium Phosphate—See *Ammonium Phosphate, Dibasic*.

Dibasic Potassium Phosphate—See *Potassium Phosphate, Dibasic*.

Dibenzyl—See *Bibenzyl*.

2,6-Dibromoquinone-chlorimide (2,6-Dibromo-N-chloro-p-benzoquinone Imine; DBQ Reagent), $\text{O}:\text{C}_6\text{H}_2\text{Br}_2:\text{NCl}$ —**299.35** [537-45-1]—A yellow, crystalline powder. Insoluble in water; soluble in alcohol and in dilute alkali hydroxide solutions.

Melting range (741): between 82° and 84°.

Solubility in alcohol—A solution of 100 mg in 10 mL of alcohol is not more than faintly turbid.

Residue on ignition (Reagent test)—Ignite 500 mg with 0.5 mL of sulfuric acid: the residue weighs not more than 1 mg (0.2%).

Sensitiveness—To 10 mL of a water solution containing 0.01 mg of phenol add 0.3 mL of a sodium borate buffer

(made by dissolving 2.84 g of crystallized sodium borate in 90 mL of warm water, adding 8.2 mL of 1 N sodium hydroxide, and diluting with water to 100 mL) and 0.1 mL of a solution of 10 mg of the test specimen in 20 mL of alcohol: a distinct blue color develops within 10 minutes.

Dibutyl Phthalate, $\text{C}_{16}\text{H}_{22}\text{O}_4$ —**278.34** [84-74-2]—Clear, colorless liquid.

Assay—Accurately weigh about 2 g into a suitable flask, add 25.0 mL of 1 N sodium hydroxide and 30 mL of isopropyl alcohol, and mix. Digest the mixture at a temperature near boiling for 30 minutes, then cool in a water bath to room temperature. Add phenolphthalein TS, and titrate with 1 N sulfuric acid VS to the disappearance of the pink color. Perform a complete blank determination, and make any necessary correction. Each mL of 1 N sulfuric acid consumed is equivalent to 139.2 mg of $\text{C}_{16}\text{H}_{22}\text{O}_4$. Not less than 98% is found.

Refractive index (831): between 1.491 and 1.493 at 20°.

Acid content—Accurately weigh about 10 g, and dissolve in 100 mL of an alcohol-ether mixture (1:1). Add phenolphthalein TS, and titrate immediately with 0.05 N alcoholic potassium hydroxide VS. Each mL of 0.05 N alcoholic potassium hydroxide is equivalent to 4.15 mg of phthalic acid: not more than 0.02% is found.

Dibutylamine, $\text{C}_8\text{H}_{19}\text{N}$ —**129.24** [111-92-2]—Colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μm layer of phase G2; the injection port temperature is maintained at 200°; the detector temperature is maintained at 300°; and the column temperature is maintained at 100° and programmed to rise 10° per minute to 200°. The area of the $\text{C}_8\text{H}_{19}\text{N}$ peak is not less than 99% of the total peak area.

Refractive index (831): between 1.415 and 1.419 at 20°.

Dibutylammonium Phosphate—Use a suitable grade.

[NOTE—A suitable grade is available as PIC Reagent D4 from Waters Corporation, www.waters.com.]

1,3-Dicaffeoylquinic Acid (Cynarin; (1R,3R,4S,5R)-1,3-Bis-[[3-(3,4-dihydroxyphenyl)propenoyl]oxy]-4,5-dihydroxycyclohexanecarboxylic Acid), $\text{C}_{25}\text{H}_{24}\text{O}_{12}$ —**516.45** [30964-13-7]—Use a suitable grade.

[NOTE—A suitable grade is available as catalog number 3991 from www.chromadex.com.]

Dichloroacetic Acid, $\text{C}_2\text{H}_2\text{Cl}_2\text{O}_2$ —**128.9** [79-43-6]—Colorless liquid. Miscible with water, with alcohol, and with ether. Use a suitable grade.

2,5-Dichloroaniline, $\text{Cl}_2\text{C}_6\text{H}_3\text{NH}_2$ —**162.02** [95-82-9]—White, needle-like crystals. Slightly soluble in water; soluble in alcohol and in ether.

Melting range, Class I (741): between 49° and 50°.

2,6-Dichloroaniline, $\text{C}_6\text{H}_3\text{Cl}_2\text{N}$ —**162.02** [608-31-1]—Off-white powder.

Melting range (741): between 38° and 41°.

o-Dichlorobenzene, $\text{C}_6\text{H}_4\text{Cl}_2$ —**147.00** [95-50-1]—Clear liquid, having a light yellowish-brown tint (about APHA 20). Practically insoluble in water. Miscible with alcohol and with ether. Boils at about 180°.

Assay—When examined by gas-liquid chromatography, with the use of suitable apparatus and conditions, it shows a purity of not less than 98%.

Density: between 1.299 and 1.301.

Refractive index (831): between 1.548 and 1.550 at 25°.

Residue on evaporation—Evaporate 80 mL on a steam bath, and dry at 105° for 1 hour: the residue weighs not more than 50 mg (0.005%).

Acidity—Add phenolphthalein TS to 25 mL of methanol, and titrate with 0.02 N alcoholic potassium hydroxide VS

until a faint pink color persists for 15 seconds. Pipet 25 mL of test specimen into the solution; mix, avoiding exposure to the atmosphere; and titrate with 0.02 N alcoholic potassium hydroxide VS: not more than 2.2 mL is required to restore the pink color (about 0.005%).

1,2-Dichloroethane—See *Ethylene Dichloride*.

Dichlorofluorescein, $C_{20}H_{10}Cl_2O_5$ —**401.20** [76-54-0]—[NOTE—This specification covers both the 4,5- and 2,7-isomers of dichlorofluorescein, either of which is suitable for the preparation of dichlorofluorescein TS.] A weak orange-colored, crystalline powder. Sparingly soluble in water; soluble in alcohol and in solutions of alkali hydroxides.

Residue on ignition (Reagent test)—Ignite 200 mg with 5 drops of sulfuric acid: the residue weighs not more than 1 mg (0.5%).

Sensitiveness—Dissolve 100 mg in 60 mL of alcohol, add 2.5 mL of 0.1 N sodium hydroxide, and dilute with water to 100 mL. Add 1 mL of this solution to a solution of potassium iodide prepared by dissolving 100 mg of potassium iodide, previously dried at 105° to constant weight and accurately weighed, in 50 mL of water containing 1 mL of glacial acetic acid, and titrate with 0.1 N silver nitrate VS until the color of the precipitate changes from pale yellowish-orange to pink. The volume of 0.1 N silver nitrate consumed is not more than 0.10 mL greater than the calculated volume, the calculated volume being based upon the KI content of the dried specimen as determined in the *Assay* under *Potassium Iodide* (USP monograph).

Dichlorofluoromethane, $CHCl_2F$ —**102.92** [75-43-4]—Colorless gas.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a thermal-conductivity detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.53-mm \times 30-m capillary column coated with a 5- μ m layer of phase G2; the injection port temperature is maintained at 200°; the detector temperature is maintained at 200°; and the column temperature is maintained at 0° and programmed to rise 5° per minute to 40°, and then to rise 10° per minute to 180°. The area of the $CHCl_2F$ peak is not less than 98% of the total peak area.

2,6-Dichloroindophenol Sodium—See *2,6-Dichlorophenol-indophenol Sodium*.

Dichloromethane—Use *Methylene Chloride*.

2,4-Dichloro-1-naphthol, $C_{10}H_6OCl_2$ —**213.06** [2050-76-2]—Light tan powder.

Melting range (741): between 103° and 107°, but the range between beginning and end of melting does not exceed 2°.

2,6-Dichlorophenol-indophenol Sodium (*2,6-Dichloroindophenol Sodium*), $O:C_6H_2Cl_2:NC_6H_4ONa$ with about $2H_2O$ —**290.08** (anhydrous) [620-45-1]—Use ACS reagent grade.

2,6-Dichlorophenylacetic Acid, $C_8H_6Cl_2O_2$ —**205.04** [6575-24-2]—White powder.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 250°; the detector temperature is maintained at 300°; and the column temperature is maintained at 150° and programmed to rise 10° per minute to 280°. The area of the $C_8H_6Cl_2O_2$ peak is not less than 97% of the total peak area.

2,6-Dichloroquinone-chlorimide (*2,6-Dichloro-N-chloro-p-benzoquinone Imine*), $O:C_6H_2Cl_2:NCl$ —**210.44**—Pale yellow,

crystalline powder. Insoluble in water; soluble in alcohol and in dilute alkali hydroxide solutions.

Melting range (741): between 65° and 67°.

Solubility in alcohol—A solution of 100 mg in 10 mL of alcohol is complete and clear.

Residue on ignition—Ignite 500 mg with 0.5 mL of sulfuric acid: the residue weighs not more than 1 mg (0.2%).

Sensitiveness—It meets the requirements of the test for *Sensitiveness* under *2,6-Dibromoquinone-chlorimide*.

Dicyclohexyl, (*Bicyclohexyl*) $C_{12}H_{22}$ —**166.31**

[92-51-3]—Use a suitable grade.

Dicyclohexyl Phthalate, $C_{20}H_{26}O_4$ —**330.42** [84-61-7].

Melting range (741): between 62° and 66°.

Dicyclohexylamine, $(C_6H_{11})_2NH$ —**181.32** [101-83-7]—

Clear, strongly alkaline liquid. Sparingly soluble in water.

Miscible with common organic solvents. Use a suitable grade with a content of not less than 98%.

Diethylamine, $(C_2H_5)_2NH$ —**73.14** [109-89-7]—Colorless, flammable, strongly alkaline liquid. Miscible with water and with alcohol. Forms a hydrate with water. *May be irritating to skin and mucous membranes*. Store in well-closed containers. Use ACS reagent grade.

Diethylamine Phosphate (*Phosphoric Acid: Diethylamine*), $C_4H_{11}N \cdot H_3PO_4$ —**171.13** [68109-72-8]—Use a suitable grade. [NOTE—A suitable grade is available from www.richmanchemical.com.]

N,N-Diethylaniline, $C_6H_5N(C_2H_5)_2$ —**149.23** [91-66-7]—Light yellow to amber liquid.

Assay—Inject an appropriate specimen (about 0.2 μ L) into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas flowing at about 40 mL per minute. The following conditions have been found suitable: a 3-mm \times 1.8-m stainless steel column containing 20% phase G16 on support S1A; the injection port temperature is maintained at 250°; the column temperature is maintained at 140° and programmed to rise 6° per minute to 200°. The detector temperature is maintained at 310°. The area of the *N,N*-diethylaniline peak having a retention time of about 4.9 minutes is not less than 99% of the total peak area.

Refractive index (831): between 1.5405 and 1.5425 at 20°.

Diethylene Glycol, (*Bis(2-hydroxyethyl) Ether; Diglycol*;

2-Hydroxyethyl Ether; 2,2'-Oxydiethanol), $C_4H_{10}O_3$ —**106.12**

[111-46-6]—A colorless to faintly yellow, viscous, hygroscopic liquid. Miscible with water, with alcohol, with ether, and with acetone. Insoluble in benzene and in carbon tetrachloride. Use a suitable grade with a content of not less than 99.0%.

Di(ethylene glycol) Methyl Ether (*2-(2-Methoxyethoxy)ethanol; Methyl diglycol*), $C_5H_{12}O_3$ —**120.15**

[111-77-3]—Use a suitable grade.

Diethylene Glycol Succinate Polyester, $(OCH_2CH_2OCH_2CH_2OOCCH_2CH_2COO)_n$ [26183-02-8]—Clear, viscous liquid. Soluble in chloroform. Is stabilized by modification of the diethylene glycol succinate polyester, to render it suitable for use in gas-liquid chromatography to a temperature of 200°.

[NOTE—A suitable grade is available from Alltech, www.alltechweb.com.]

Diethylenetriamine, $C_4H_{13}N_3$ —**103.17** [111-40-0]—Colorless liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with G2. The injection port temperature is maintained at 200°; the column temperature is maintained at 100° and programmed to rise 10° per minute to 250° and held there for 5 minutes; and the detector temperature is maintained at 300°. The area of the main peak is not less than 95% of the total peak area.

Refractive index (831): between 1.4815 and 1.4845 at 20°.

Di(2-ethylhexyl)phthalate [*Bis(2-ethylhexyl)phthalate*], $C_{24}H_{38}O_4$ —**390.56** [117-81-7]—Use a suitable grade.

Diethylpyrocarbonate, $C_6H_{10}O_5$ —**162.14** [1609-47-8]—Clear, colorless liquid. Use a suitable grade.

Diethyl Sulfone (*Ethyl Sulfone*), $(C_2H_5)_2SO_2$ —**122.19** [597-35-3]—Use a suitable grade with NLT 97%.

Digitonin, $C_{56}H_{92}O_{29}$ —**1229.31** [11024-24-1]—White, crystalline powder. Almost insoluble in water; soluble in warm alcohol, and in glacial acetic acid and in 75% acetic acid; insoluble in chloroform and in ether. Melts at about 230°, with decomposition.

Specific rotation (781): between -47° and -49°, determined in a solution in 75% acetic acid containing 100 mg per mL.

Solubility in alcohol—A solution of 500 mg in 20 mL of warm alcohol is colorless and complete.

Loss on drying (731)—Dry it at 105° to constant weight: it loses not more than 6% of its weight.

Residue on ignition (Reagent test): not more than 0.3%.
Digoxigenin ($3\beta,12\beta,14\beta,21$ -Tetrahydroxy-20(22)-norcholenic Acid Lactone; $3\beta,12\beta,14$ -Trihydroxy- $5\beta,20(22)$ -cardenolide; $5\beta,20(22)$ -Cardenolide- $3\beta,12\beta,14$ -triol; *Lanadigenin*), $C_{23}H_{34}O_5$ —**390.51** [1672-46-4]—Use a suitable grade.

Dihydroquinidine Hydrochloride, $C_{20}H_{27}ClN_2O_2$ —**362.89** [1476-98-8]—Rhombic plates. Freely soluble in methanol and in chloroform.

Assay—

MOBILE PHASE—Prepare a mixture of water, acetonitrile, diethylamine, and methanesulfonic acid (860:100:20:20).

PROCEDURE—Inject about 20 μ L into a suitable liquid chromatograph (see *Chromatography* (621)) equipped with a 235-nm detector and a 4.6-mm \times 15-cm column that contains packing L1. The flow rate is about 1.5 mL per minute. The area of the $C_{20}H_{27}ClN_2O_2$ peak is not less than 97.5% of the total peak area.

Dihydroquinine (*Hydroquinine*), $C_{20}H_{26}N_2O_2$ —**326.43** [522-66-7]—Freely soluble in acetone, in alcohol, and in chloroform; almost insoluble in water.

Assay—

MOBILE PHASE—Prepare a mixture of water, acetonitrile, diethylamine, and methanesulfonic acid (860:100:20:20) and methanol (82:18).

PROCEDURE—Inject about 20 μ L into a suitable liquid chromatograph (see *Chromatography* (621)) equipped with a 235-nm detector and a 4.6-mm \times 15-cm column that contains packing L1. The flow rate is about 1.5 mL per minute. The area of the $C_{20}H_{26}N_2O_2$ peak is not less than 97.5% of the total peak area.

2,5-Dihydroxybenzoic Acid, $C_7H_6O_4$ —**154.12** [303-07-1]—Off-white powder. Freely soluble in alcohol yielding a clear, very pale yellow solution.

Assay—Dissolve about 75 mg, accurately weighed, in 30 mL of methanol. Slowly add 40 mL of water. Titrate with 0.1 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination, and make

any necessary correction. Each mL of 0.1 N sodium hydroxide is equivalent to 15.41 mg of $C_7H_6O_4$. Not less than 99% is found.

Melting range (741): about 207°, with decomposition.

2,7-Dihydroxynaphthalene—See *2,7-Naphthalenediol*.

Diiodofluorescein, $C_{20}H_{10}I_2O_5$ —**584.10** [31395-16-1]—Orange-red powder. Slightly soluble in water; soluble in alcohol and in solutions of alkali hydroxides.

Residue on ignition—Ignite 200 mg with 5 drops of sulfuric acid: the weight of the residue does not exceed 1.0 mg (0.5%).

Sensitiveness—Accurately weigh about 100 mg of potassium iodide, previously dried at 105° to constant weight, and dissolve it in 50 mL of water. Add 1 mL of diiodofluorescein TS prepared from the test specimen and 1 mL of glacial acetic acid, and titrate with 0.1 N silver nitrate VS until the color of the precipitate changes from brownish-red to a bluish-red. The volume of 0.1 N silver nitrate consumed is not in excess of 0.10 mL over the calculated volume, based on the KI content of the dried potassium iodide determined as follows. Dissolve about 500 mg of potassium iodide, accurately weighed, in about 10 mL of water, and add 35 mL of hydrochloric acid and 5 mL of chloroform. Titrate with 0.05 M potassium iodate VS until the purple color of iodine disappears from the chloroform. Add the last portions of the iodate solution dropwise, agitating vigorously and continuously. After the chloroform has been decolorized, allow the mixture to stand for 5 minutes. If the chloroform develops a purple color, titrate further with the iodate solution. Each mL of 0.05 M potassium iodate is equivalent to 16.60 mg of KI.

Diisodecyl Phthalate [*Bis(isodecyl)phthalate*], $C_{28}H_{46}O_4$ —**446.66** [26761-40-0]—Use a suitable grade.

Diisopropyl Ether (*Isopropyl Ether*), $[(CH_3)_2CH]_2O$ —**102.17** [108-20-3]—Colorless, mobile liquid. Slightly soluble in water. Miscible with alcohol and with ether.

[CAUTION]—It is highly flammable. Do not use where it may be ignited. Do not evaporate to the point of near dryness, since it tends to form explosive peroxides.]

Specific gravity: between 0.716 and 0.720.

Distilling range, Method II (721)—Not less than 95% distills between 65° and 70°.

Peroxides—To 10 mL, contained in a clean, glass-stoppered cylinder previously rinsed with a portion of the ether under examination, add 1 mL of freshly prepared potassium iodide solution (1 in 10). Shake, and allow to stand for 1 minute: no yellow color is observed in either layer (about 0.001% as H_2O_2).

Residue on evaporation—[NOTE—If peroxide is present, do not carry out this procedure.] Evaporate 14 mL (10 g) from a tared shallow dish, and dry at 105° for 1 hour: the residue weighs not more than 1 mg (0.01%).

Acidity—Add 2 drops of bromothymol blue TS to 10 mL of water in a glass-stoppered, 50-mL flask, and titrate with 0.010 N sodium hydroxide until a blue color persists after vigorous shaking. Add 5 mL of diisopropyl ether, and titrate with 0.010 N sodium hydroxide: not more than 0.30 mL is required to restore the blue color (0.005% as CH_3COOH).

[NOTE—For spectrophotometric determinations, use diisopropyl ether that meets the following additional requirement:]

Absorbance—Its absorbance at 255 nm, in a 10-mm quartz cell, does not exceed 0.2, water being used as the blank.

Diisopropylamine, $[(CH_3)_2CH]_2NH$ —**101.19** [108-18-9]—Colorless liquid.

Assay—Not less than 98% of $C_6H_{15}N$ is found, a suitable gas chromatograph equipped with a flame-ionization detector being used. The following conditions have been found suitable: a 3.2-mm \times 1.83-m stainless steel column is packed with a cross-linked polystyrene support; the injection port temperature is maintained at 250° and the detector

temperature at 310°; the column temperature is programmed to rise at 10° per minute from 50° to 220°.

Refractive index (831): between 1.3915 and 1.3935, at 20°.

Diisopropylethylamine (*N,N*-Diisopropylethylamine), $C_8H_{19}N$ —**129.24** [7087-68-5]—Clear, colorless liquid. Soluble in glacial acetic acid.

Assay—Accurately weigh about 500 mg, dissolve in 50 mL of glacial acetic acid, mix, add crystal violet TS, and titrate with 0.1 N perchloric acid VS. Each mL of 0.1 N perchloric acid is equivalent to 12.92 mg of $C_8H_{19}N$. Not less than 98% is found.

Refractive index (831): between 1.4125 and 1.4145 at 20°.

1,2-Dilinoleoyl-3-oleoyl-rac-glycerol, $C_{57}H_{100}O_6$ —**881.4** [2190-21-8]—Use a suitable grade.

1,2-Dilinoleoyl-3-palmitoyl-rac-glycerol, $C_{55}H_{98}O_6$ —**855.4** [2190-15-0]—Use a suitable grade.

Diluted Acetic Acid—See *Acetic Acid, Diluted*.

Diluted Alcohol—Use *Diluted Alcohol* (NF monograph).

Diluted Hydrochloric Acid—See *Hydrochloric Acid, Diluted*.

Diluted Nitric Acid—See *Nitric Acid, Diluted*.

Diluted Sulfuric Acid—See *Sulfuric Acid, Diluted*.

Dimethicone, viscosity 500 centistokes (*Poly(dimethylsiloxane), viscosity 500 centistokes*), $[-Si(CH_3)_2O-]_n$ [63148-62-9]—Use a suitable grade.

2,5-Dimethoxybenzaldehyde, $C_9H_{10}O_3$ —**166.17** [93-02-7]—Off-white crystals.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, nitrogen being used as the carrier gas. The following conditions have been found suitable: a 0.3-mm \times 30-m capillary column coated with phase G1; the injection port temperature is maintained at 270°; the detector temperature is maintained at 300°; the column temperature is maintained at 150° and programmed to rise 10° per minute to 270°. The area of the main peak is not less than 97% of the total peak area.

Melting range (741): between 50° and 52°.

1,2-Dimethoxyethane, $C_4H_{10}O_2$ —**90.12** [110-71-4]—Clear, colorless liquid. Miscible with water and with alcohol. Soluble in hydrocarbon solvents. May form peroxides on standing.

Boiling range (Reagent test)—Not less than 95% distills between 83° and 86°.

Refractive index (831): between 1.379 and 1.381, at 20°.

Acidity—To 20 mL add bromophenol blue TS, and titrate with 0.020 N sodium hydroxide: not more than 2.0 mL is consumed (about 0.015% as CH_3COOH).

Water, Method I (921): not more than 0.2%.

Dimethoxymethane (*Formaldehyde Dimethyl Acetal, Methylal*), $C_3H_8O_2$ —**76.10** [109-87-5]—Use a suitable grade.

(3,4-Dimethoxyphenyl)acetone (*Homoveratrol*), $C_{10}H_{11}NO_2$ —**177.20** [93-17-4]—Off-white fibers.

Melting range (741): between 65° and 67°.

Dimethyl Phthalate, $C_{10}H_{10}O_4$ —**194.19** [131-11-3]—Viscous, colorless liquid.

Assay—

MOBILE PHASE—Prepare a filtered and degassed mixture of chromatographic *n*-heptane and *n*-propyl alcohol (HPLC grade) (97:3). Make adjustments if necessary (see *System Suitability* under *Chromatography* (621)).

STANDARD SOLUTION—Dissolve a suitable quantity of dimethyl phthalate in *Mobile phase* to obtain a solution having a known concentration of about 0.26 mg per mL.

PROCEDURE—Inject about 20 μ L into a suitable liquid chromatograph (see *Chromatography* (621)) equipped with a 238-nm detector and a 4.6-mm \times 25-cm column that contains packing L10. The flow rate is about 1.0 mL per minute.

The area of the dimethyl phthalate peak is not less than 99% of the total peak area.

Refractive index (831): between 1.514 and 1.518 at 20°.

Dimethyl Sulfone (*Methyl Sulfone*), $(CH_3)_2SO_2$ —**94.13** [67-71-0]—White crystals.

Melting range (741): between 109° and 111°.

Dimethyl Sulfoxide (*Methyl Sulfoxide*), $(CH_3)_2SO$ —**78.13**—Use ACS reagent grade methyl sulfoxide.

Dimethyl Sulfoxide, Spectrophotometric Grade [67-68-5]—Use methyl sulfoxide ACS spectrophotometric reagent grade.

***N,N*-Dimethylacetamide**, C_4H_9NO —**87.12**

[127-19-5]—Clear, colorless liquid. Miscible with water and with many organic solvents. Use a suitable HPLC or spectroscopic grade.

***p*-Dimethylaminoazobenzene** (*Methyl Yellow, Butter Yellow*), $C_6H_5N:NC_6H_4N(CH_3)_2$ —**225.29** [60-11-7]—Yellow leaflets or yellow, crystalline powder.

Solubility—Insoluble in water; sparingly soluble in chloroform, in ether, or in fatty oils. Dissolve 100 mg in 20 mL of alcohol: the solution is complete or practically so and clear.

Melting range (741): between 115° and 117°.

Residue on ignition (281): not more than 0.1%.

Sensitiveness—Add 0.05 mL of an alcohol solution (1 in 200) and 2 g of ammonium chloride to 25 mL of carbon dioxide-free water: the lemon-yellow color of the solution is changed to orange by the addition of 0.05 mL of 0.1 N hydrochloric acid and restored on the subsequent addition of 0.05 mL of 0.1 N sodium hydroxide.

***p*-Dimethylaminobenzaldehyde**, $(CH_3)_2NC_6H_4CHO$ —**149.19** [100-10-7]—Use ACS reagent grade.

***p*-Dimethylaminocinnamaldehyde**, $(CH_3)_2NC_6H_4CH:CHCHO$ —**175.23**—Orange-yellow powder. Soluble in acetone, in alcohol, and in benzene.

Melting range (741): between 132° and 136°.

2-Dimethylaminoethyl Methacrylate, $C_8H_{15}NO_2$ —**157.2** [2867-47-2]—Use a suitable grade.

Dimethylaminophenol (*meta isomer*), $C_8H_{11}NO$ —**137.18**—Purplish-black, gray, or tan-colored, crystalline solid.

Melting range (741): between 83° and 85°.

2,6-Dimethylaniline, C_8H_9N —**121.18** [87-62-7]—Yellow liquid.

Refractive index (831): about 1.5609 at 20°.

***N,N*-Dimethylaniline**, C_8H_9N —**121.18** [121-69-7]—Light yellow liquid. Clear, colorless liquid when freshly distilled, but acquiring a reddish to reddish-brown color. Specific gravity: about 0.960. Freezing point about 2°. Insoluble in water; soluble in alcohol, in chloroform, in ether, and in dilute mineral acids.

Assay—Inject an appropriate specimen (about 0.2 μ L) into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas flowing at about 40 mL per minute. The following conditions have been found suitable: a 3-mm \times 1.8-m stainless steel column containing 20% phase G16 on support S1A; the injection port temperature is maintained at 250°; the column temperature is maintained at 50° and programmed to rise 10° per minute to 200°. The detector temperature is maintained at 310°. The area of the *N,N*-dimethylaniline peak having a retention time of about 11.5 minutes is not less than 99% of the total peak area.

Refractive index (831): between 1.5571 and 1.5591 at 20°.

Boiling range (Reagent test)—Distill 100 mL: the difference between the temperatures observed, when 1 mL and 95 mL have distilled, is not more than 2.5°. Its boiling temperature at a pressure of 760 mm of mercury is 194.2°.

Hydrocarbons—Dissolve 5 mL in a mixture of 10 mL of hydrochloric acid and 15 mL of water: a clear solution results and it remains clear on cooling to about 10°.

Aniline or monomethylaniline—Place 5 mL in a glass-stoppered flask, add 5 mL of a solution of acetic anhydride in benzene (1 in 10), mix, and allow to stand for 30 minutes. Add 30.0 mL of 0.5 N sodium hydroxide VS, shake the mixture, add phenolphthalein TS, and titrate with 0.5 N hydrochloric acid VS. Perform a blank determination, and make any necessary correction. Not more than 0.30 mL of 0.5 N sodium hydroxide is consumed by the test specimen.

3,4-Dimethylbenzophenone, $C_{15}H_{14}O$ —**210.27**

[2571-39-3]—White chunks melting at about 45°.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with phase G1; the detector temperature and the injection port temperature are maintained at 300°; the column temperature is maintained at 180° and programmed to rise at the rate of 10° per minute to 280° and held at that temperature for 10 minutes. The area of the main peak is not less than 99% of the total peak area.

5,5-Dimethyl-1,3-cyclohexanedione, $C_8H_{12}O_2$ —**140.18**

[126-81-8]—White, crystalline solid. Slightly soluble in water; soluble in alcohol, in methanol, in chloroform, and in acetic acid.

Melting range (741): between 148° and 150°.

N,N-Dimethyldodecylamine (1-(Dimethylamino)decane), $C_{14}H_{29}NO$ —**185.35** [1120-24-7]—Use a suitable grade with a content of not less than 98%.

1,5-Dimethyl-1,5-diazaundecamethylene polymethobromide (Polybrene), [28728-55-4]—This is a positively charged polymer. It is available as an off-white, crystalline solid or powder and is extremely hygroscopic. Use a suitable reagent grade.

[NOTE—Commercially available as Polybrene.]

N,N-Dimethyldodecylamine-N-oxide (Lauryldimethylamine-N-oxide), $CH_3(CH_2)_{11}NO(CH_3)_2$ —**229.40**

[1643-20-5]—Use a suitable grade. [NOTE—N,N-Dimethyldodecylamine-N-oxide, 0.1 N in Water and N,N-Dimethyldodecylamine-N-oxide, 30 Percent are suitable grades as well.]

Dimethylethyl(3-hydroxyphenyl)ammonium Chloride—See *Edrophonium Chloride*.

Dimethylformamide (N,N-Dimethylformamide), $HCON(CH_3)_2$ —**73.09** [68-12-2]—Use ACS reagent grade.

N,N-Dimethylformamide Diethyl Acetal—**147.22** [1188-33-6]—Use a suitable grade.

[NOTE—A suitable grade is available from Sigma-Aldrich, www.sigma-aldrich.com.]

1,3-Dimethyl-2-imidazolidinone, $C_5H_{10}N_2O$ —**114.15** [80-73-9]—Use a suitable grade.

1,9-Dimethyl-methylene Blue, $C_{36}H_{46}Cl_4N_6OS_2Zn$ —**850.1** [23481-50-7]—Dark green powder. Use a suitable grade.

[NOTE—A suitable grade is available from Sigma-Aldrich, www.sigma-aldrich.com.]

N,N-Dimethyl-1-naphthylamine, $C_{12}H_{13}N$ —**171.24**

[86-56-6]—Pale yellow to yellow, aromatic liquid. Soluble in alcohol and in ether.

Assay—Transfer about 250 mg, accurately weighed, to a suitable beaker, add 100 mL of glacial acetic acid, and dissolve by stirring. When solution is complete, titrate with 0.1 N perchloric acid VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N perchloric acid is equivalent to 17.12 mg of $C_{12}H_{13}N$. Not less than 98% is found.

Refractive index (831): between 1.6210° and 1.6230° at 20°, sodium light being used.

Sulfanilamide test—Dissolve 20 mg of USP Sulfanilamide RS in 100 mL of water to obtain the *Sulfanilamide solution*. Into two 150-mL beakers pipet 1.0 mL and 2.5 mL of the *Sulfanilamide solution*, respectively. Dilute with water to 90 mL. To provide a blank, place 90 mL of water in a third beaker. To each beaker add 8.0 mL of trichloroacetic acid solution (3 in 20) and 1.0 mL of sodium nitrite solution (1 in 1000). Stir the solutions for 5 minutes, then add 10 mL of acetate buffer TS, and 1.0 mL of a 1 in 1000 solution of N,N-dimethyl-1-naphthylamine in alcohol. The pH is about 5 to 6, using pH paper. Stir for an additional 5 minutes, then add 20 mL of glacial acetic acid. The pH is about 3 to 4, using pH paper. In comparison with the blank, the beaker containing 1.0 mL of the *Sulfanilamide solution* shows a pink color, while the other beaker shows a deep pink to red color.

N,N-Dimethyloctylamine, $C_{10}H_{23}N$ —**157.30**

[7378-99-6]—Colorless liquid.

Refractive index (831): 1.4243 at 20°.

2,5-Dimethylphenol, $C_8H_{10}O$ —**122.16** [95-87-4]—Use a suitable grade.

2,6-Dimethylphenol, $(CH_3)_2C_6H_3OH$ —**122.16** [576-26-1]—White to pale yellow, crystalline solid.

Assay—Inject a 1 in 3 solution of it in xylene into a suitable gas chromatograph equipped with a flame-ionization detector, helium being used as the carrier gas at a flow rate of about 40 mL per minute. The following conditions have been found suitable: a 3.2-mm \times 1.83-m stainless steel column packed with 10% phase G25 on support S1A; the injection port temperature is maintained at about 250° and the detector temperature at about 310°; the column temperature is programmed to rise at 8° per minute from 100° to 200°. Similarly inject a specimen of xylene. The area of the $C_8H_{10}O$ peak is not less than 98% of the total peak area corrected for xylene.

Melting range (741): between 44° and 46°.

3,5-Dimethylphenol, $C_8H_{10}O$ —**122.16** [108-68-9]—Use a suitable grade.

[NOTE—A suitable grade is available as product number 5600 from www.alfa.com.]

N,N-Dimethyl-p-phenylenediamine Dihydrochloride, $(CH_3)_2NC_6H_4NH_2 \cdot 2HCl$ —**209.12** [99-89-9]—Nearly white, fine, crystalline, hygroscopic solid that may have a pinkish cast. Freely soluble in water; soluble in alcohol.

Assay—Transfer about 400 mg, accurately weighed, to a 250-mL beaker, and dissolve in about 75 mL of water. Titrate with 0.1 N sodium hydroxide VS, determining the endpoint potentiometrically. Each mL of 0.1 N sodium hydroxide is equivalent to 10.46 mg of $C_8H_{12}N_2 \cdot 2HCl$. Not less than 98% is found.

Solubility—A solution of 1 g in 10 mL of water produces not more than a slight haze.

3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyl Tetrazolium Bromide, $C_{18}H_{16}N_5SBr$ —**414.3** [298-93-1]—Yellow to orange powder. Use a suitable grade.

Dimethyltin Dibromide, $C_2H_6Br_2Sn$ —**308.59** [2767-47-7]—Use a suitable grade.

m-Dinitrobenzene, $C_6H_4(NO_2)_2$ —**168.11** [99-65-0]—Pale yellow crystals or crystalline powder. Almost insoluble in cold water; slightly soluble in hot water. Soluble in chloroform and in benzene; sparingly soluble in alcohol. Is volatile in steam.

Melting range (741): between 89° and 92°.

Residue on ignition (Reagent test): not more than 0.5%.

3,5-Dinitrobenzoyl Chloride, $C_7H_3ClN_2O_5$ —**230.56**

[99-33-2]—Pale yellow, crystalline powder. Freely soluble in dilute sodium hydroxide solutions; soluble in alcohol.

[CAUTION—Corrosive, moisture-sensitive, lachrymator, and possible mutagen. Store under nitrogen.]

Melting range (741): between 69° and 71°.

Solubility in sodium hydroxide—A solution of 500 mg in 25 mL of 1 N sodium hydroxide is clear or not more than faintly turbid.

Residue on ignition—Ignite 1 g with 0.5 mL of sulfuric acid: the residue weighs not more than 1 mg (0.1%).

2,4-Dinitrochlorobenzene, $C_6H_3(NO_2)_2Cl$ —**202.55** [97-00-7]—Yellow to brownish-yellow crystals. Insoluble in water; soluble in hot alcohol, in ether, and in benzene.

Melting range (741): between 51° and 53°.

Residue on ignition—Ignite 500 mg with 5 drops of sulfuric acid: the residue weighs not more than 1 mg (0.2%).

2,4-Dinitrofluorobenzene (1-Fluoro-2,4-dinitrobenzene), $C_6H_3FNO_2$ —**186.10** [70-34-8]—Light yellow solid. Use a suitable grade.

2,4-Dinitrophenylhydrazine, $2,4-C_6H_3(NO_2)_2NHNH_2$ —**198.14** [119-26-6]—Orange-red crystals, which under the microscope appear individually to be lemon-yellow, lath-like needles. Very slightly soluble in water; slightly soluble in alcohol; moderately soluble in dilute inorganic acids. Use a suitable grade with a content of not less than 97%.

Diocetyl Sodium Sulfosuccinate—Use *Docosate Sodium*.

Dioxane (Diethylene Dioxide; 1,4-Dioxane), $C_4H_8O_2$ —**88.11** [123-91-1]—Use ACS reagent grade.

Diphenyl Ether (Phenyl Ether), $(C_6H_5)_2O$ —**170.21** [101-84-8]—A colorless liquid. Insoluble in water; soluble in glacial acetic acid and in most organic solvents. Boils at about 259°.

Melting range (741): between 26° and 28°.

Diphenylamine, $(C_6H_5)_2NH$ —**169.22** [122-39-4]—Use ACS reagent grade.

Diphenylborinic Acid, Ethanolamine Ester, (2-Aminoethyl Diphenylborinate) $C_{14}H_{16}BNO$ —**225.09**—White, crystalline powder. Use a suitable grade.

Melting range (741): between 192° and 194°.

Diphenylcarbazine, $(C_6H_5NHNH)_2CO$ —**242.28** [140-22-7]—Use ACS reagent grade 1,5-Diphenylcarbohydrazide.

Diphenylcarbazon [Diphenylcarbazon compd. with *s*-Diphenylcarbazol (1:1)], $C_6H_5NHNHCON:NC_6H_5 \cdot C_6H_5NHNHCONHNHC_6H_5$ —**482.54** [538-62-5]—Use ACS reagent grade Diphenylcarbazon Compound with *s*-Diphenylcarbazide (1:1).

2,2-Diphenylglycine, $C_{14}H_{13}NO_2$ —**227.26** [3060-50-2]—Off-white powder. Melts at about 244°, with decomposition.

Assay—Dissolve about 115 mg, accurately weighed, in 30 mL of methanol. Slowly add about 20 mL of water, heating slightly if necessary for complete solution. Titrate with 0.1 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination and make any necessary correction. Each mL of 0.1 N sodium hydroxide is equivalent to 22.73 mg of $C_{14}H_{13}NO_2$. Not less than 98.0% is found.

Dipicrylamine—See *Hexanitrodiphenylamine*.

Dipropyl Phthalate, $C_{14}H_{18}O_4$ —**250.29** [131-16-8]—Viscous, colorless liquid.

Assay—

MOBILE PHASE—Prepare a mixture of acetonitrile and water (52:48).

PROCEDURE—Inject about 20 μ L into a suitable liquid chromatograph (see *Chromatography* (621)) equipped with a 230-nm detector and a 4.6-mm \times 15-cm column that contains packing L1. The flow rate is about 2.0 mL per minute. The area of the $C_{14}H_{18}O_4$ peak is not less than 99% of the total peak area.

Refractive index (831): between 1.495 and 1.499 at 20°.

4,4'-Dipyridyl, $C_{10}H_8N_2$ —**156.18** [553-26-4]—Use a suitable grade. [NOTE—A suitable grade is available from Sigma-Aldrich Catalog number 289426.]

α, α' -Dipyridyl—See 2,2'-Bipyridine.

Disodium Chromotropate (4,5-Dihydroxy-2,7-naphthalenedisulfonic Acid, Disodium Salt), $C_{10}H_6O_8S_2Na_2 \cdot 2H_2O$ —**400.29**—Use ACS reagent grade Chromotropic Acid Disodium Salt.

Disodium Ethylenediaminetetraacetate—See *Edetate Disodium*.

Disodium Phosphate—See *Sodium Phosphate*.

5,5'-Dithiobis(2-nitrobenzoic Acid) (3-Carboxy-4-nitrophenyl disulfide; Ellman's reagent), $C_{14}H_8N_2O_8S_2$ —**396.35** [69-78-3]—Yellow powder, melting at about 242°. Sparingly soluble in alcohol.

Dithiothreitol (Cleland's Reagent; Threo-1,4-dimercapto-2,3-butanediol; DTT), $HSCH_2CH(OH)CH(OH)CH_2SH$ —**154.25** [3483-12-3]—Slightly hygroscopic needles from ether. Freely soluble in water, in alcohol, in acetone, in ethyl acetate, and in ether.

Melting range (741): between 42° and 44°.

Dithizone (Diphenylthiocarbazone; Phenylazothioformic Acid 2-Phenylhydrazide), $C_6H_5N:NCSNHNHC_6H_5$ —**256.33** [60-10-6]—Use ACS reagent grade.

1-Dodecanol (Dodecyl Alcohol), $CH_3(CH_2)_{11}OH$ —**186.33** [112-53-8]—A clear, colorless liquid. Crystallizes as leaflets from dilute alcohol solution. Use ACS reagent grade.

Dodecyl Alcohol—See 1-Dodecanol.

Dodecyl Lithium Sulfate (Lithium Dodecyl Sulfate, Lithium Lauryl Sulfate), $C_{12}H_{25}LiO_4S$ —**272.3** [2044-56-6]—White to off-white powder, clear to slightly hazy, colorless to faint yellow solution in water at 50 mg per mL at ambient temperature. The UV absorbance of a 0.1 M solution is less than 0.05 at both 260 and 280 nm. The pH of a 0.1 M solution in water is 7.0 ± 0.5 . Use a suitable grade.

Dodecyl Sodium Sulfonate (Sodium 1-Dodecanesulfonate; 1-Dodecanesulfonic Acid, Sodium Salt), $C_{12}H_{25}SO_3Na$ —**272.38** [2386-53-0]—White, powdery solid. One g dissolves in 50 mL of warm water to yield a clear, colorless solution. Use a suitable grade.

Melting point (741): higher than 300°.

3-(Dodecyltrimethylammonio)propanesulfonate (Lauryl sulfobetaine, *N,N*-dimethyl-*N*-dodecyl-*N*-(3-sulfopropyl) ammonium betaine), $C_{17}H_{37}NO_3S$ —**335.54** [14933-08-5]—Use a suitable grade.

Dodecyltriethylammonium Phosphate, 0.5 M, $[C_{12}H_{25}N \cdot (C_2H_5)_3]_3PO_4$ —**906.52**—Use a suitable grade.

[NOTE—A suitable grade is available as Ion Pair Cocktail Q12 (catalogue number 404031) from Regis Technologies, Inc., www.registech.com.]

Dodecyltrimethylammonium Bromide (Lauryltrimethylammonium bromide), $CH_3(CH_2)_{11}N(CH_3)_3Br$ —**308.3** [1119-94-4]—Use a suitable grade.

[NOTE—A suitable grade is available as catalog number D5047 from Sigma-Aldrich, www.sigma-aldrich.com.]

Drabkin's Reagent—The reagent consists of 100 parts of sodium bicarbonate, 20 parts of potassium ferricyanide, and 5 parts of potassium cyanide. [CAUTION—The reagent is HIGHLY TOXIC. Very toxic by inhalation, in contact with skin, and if swallowed, and there is a risk of serious damage to eyes. Wear suitable protective clothing, gloves, and eye and face protection. Do not mix with acids. Contact with acids liberates a very toxic gas. If ingested, perform gastric lavage, and call a physician.]

[NOTE—The reagent can be obtained from many manufacturers and suppliers. Some examples of manufacturers or suppliers are the following: Sigma Chemical Co., St. Louis, MO; and CIMA Scientific, Dallas, TX.]

Dried Peptone—See *Peptone, Dried*.

Earth, Chromatographic, Silanized, Acid-Base Washed—Use a suitable grade.

[NOTE—A suitable chromatographic grade is "Gas-Chrom Q," available from Alltech, www.alltechweb.com.]

Edetate Disodium (Disodium Ethylenediaminetetraacetate) $C_{10}H_{14}N_2O_8Na_2 \cdot 2H_2O$ —**372.24**—Use ACS reagent grade (Ethylenedinitrilo)tetraacetic Acid Disodium Salt Dihydrate.

n-Eicosane, $C_{20}H_{42}$ —**282.55** [112-95-8]—White, crystalline solid.

Melting range (741): between 37° and 39°.

Eicosanol [629-96-9]—Use a suitable grade.

Eosin Y (Eosin Yellowish Y) (Certified Biological Eosin Y; Sodium Tetrabromofluorescein), $C_{20}H_6Br_4Na_2O_5$ —**691.85** [17372-87-1]—Red to brownish-red pieces or powder. Use ACS reagent grade.

Epiandrosterone (*trans*-Androsterone, 5α -Androstan-3 β -ol-17-one), $C_{19}H_{30}O_2$ —**290.44** [481-29-8]—Use a suitable grade.

[NOTE—A suitable grade is available as catalog number E3375 from www.sigma-aldrich.com.]

Equilenin, $C_{18}H_{18}O_2$ —**266.33** [517-09-9]—Colorless or white crystals or crystalline powder. Insoluble in water; soluble in chloroform and in dioxane; moderately soluble in alcohol.

Melting range, Class II (741): between 256° and 260°.

Specific rotation (781): between +85° and +88°, determined in a solution in dioxane containing 75 mg of equilenin in each 10 mL.

Absorption maxima—An alcohol solution exhibits absorption maxima at 231, 282, 325, and 340 nm.

α -Ergocryptine, $C_{32}H_{41}N_5O_5$ —**575.70** [511-09-1]—Use a suitable grade.

Eriochrome Black T-Sodium Chloride Indicator—Mix 0.1 g of eriochrome black T and 10 g of sodium chloride, and triturate until the mixture becomes homogenous.

Eriochrome Cyanine R, $C_{23}H_{15}Na_3O_9S$ —**536.40** [3564-18-9]—Dark, red-brown powder. Freely soluble in water; insoluble in alcohol.

Solubility—200 mg in 100 mL of water yields a solution that remains clear and free from undissolved matter for 30 minutes.

Loss on drying (731)—Dry it in vacuum over silica gel to constant weight: it loses not more than 2% of its weight.

Residue on ignition (Reagent test)—0.5 g, treated with 1 mL of sulfuric acid and 2 mL of nitric acid, yields between 42.0% and 44.0% of the dry weight (theoretical yield is 42.9% of Na_2SO_4).

Sensitiveness—Add 2 mL of a solution (1 in 1000) to 1 mL of aluminum sulfate solution (1 in 10,000), heat at $37 \pm 3^\circ$ for 5 minutes, cool, and add 1 mL of sodium acetate TS: a strong red to red-violet color is produced in not more than 5 minutes.

Escin [6805-41-0]—Use a suitable grade.

Ethanesulfonic Acid, $C_2H_5SO_3H$ —**110.13** [594-45-6]—Colorless to light yellow liquid. Soluble in water.

Assay—Accurately weigh about 300 mg, dissolve in 30 mL of water, add phenolphthalein TS, and titrate with 0.1 N sodium hydroxide VS. Each mL of 0.1 N sodium hydroxide is equivalent to 11.013 mg of $C_2H_5SO_3H$: between 94.0% and 106.0% is found.

Refractive index (831): between 1.432 and 1.436 at 20°.

Ether—See *Ethyl Ether*.

Ether, Absolute—See *Ethyl Ether, Anhydrous*.

Ether, Diphenyl—See *Diphenyl Ether*.

Ether, Isopropyl—See *Diisopropyl Ether*.

Ether, Nonyl Phenyl Polyethylene Glycol—See (*p*-tert-Octylphenoxy)nonaethoxyethanol.

Ether, Peroxide-Free (*Diethyl Ether; Ether*), $(C_2H_5)_2O$ —**74.12**—Use ACS reagent grade.

Peroxide—Transfer 8 mL of potassium iodide and starch TS to a 12-mL ground glass-stoppered cylinder about 15 mm in diameter. Fill completely with the substance under test, mix, and allow to stand protected from light for 5 minutes. No color develops. Alternatively, peroxide test strips may be used.

[NOTE—Suitable peroxide test strips can be obtained from EMD Chemicals, www.emdchemicals.com, or from J. T. Baker, www.mallbaker.com.]

Ethidium Bromide, $C_{21}H_{20}N_3Br$ —**394.3** [1239-45-8]—Purple to purple-red powder. Use a suitable grade.

4'-Ethoxyacetophenone, $C_{10}H_{12}O_2$ —**164.20** [1676-63-7]—White to tan crystals.

Assay—Dissolve about 50 mg in 1 mL of ether. Inject about 1 μ L of this solution into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector and a 0.25-mm \times 30-m capillary column containing stationary phase G1. The carrier gas is helium. The chromatograph is programmed as follows. Initially, the column temperature is equilibrated at 180°, then the temperature is increased at a rate of 10° per minute to 280°, and maintained at 280° for 10 minutes. The injection port temperature is maintained at 280°, and the detector is maintained at 300°. The area of the 4'-ethoxyacetophenone peak is not less than 97.5% of the total peak area.

Melting range (741): between 34° and 39°.

2-Ethoxyethanol (*Ethylene Glycol Monoethyl Ether*), $C_4H_{10}O_2$ —**90.12** [110-80-5]—Clear, colorless liquid. Miscible with water, with alcohol, with ether, and with acetone.

Specific gravity (841): about 0.93.

Boiling range (Reagent test)—Not less than 95% distills between 133° and 135°.

Ethyl Acetate, $CH_3COOC_2H_5$ —**88.11** [141-78-6]—Use ACS reagent grade.

Ethyl Acrylate [140-88-5]—Use a suitable grade.

Ethyl Alcohol (*Alcohol; Ethanol*), C_2H_5OH —**46.07**—Use *Alcohol*.

Ethyl Arachidate, $C_{22}H_{44}O_2$ —**340.6** [18281-05-5]—Use a suitable grade.

Ethyl Benzoate, $C_9H_{10}O_2$ —**150.17** [93-89-0]—Clear, colorless liquid. Practically insoluble in water; miscible with alcohol, with chloroform, and with ether.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)), helium being used as the carrier gas. The following conditions have been found suitable: a 3-mm \times 2.4-m stainless steel column containing 20% phase G16 on support S1A; the injection port, column, and detector temperatures are maintained at 180°, 195°, and 250°, respectively. The area of the ethyl benzoate peak is not less than 98% of the total peak area.

Refractive index (831): between 1.5048 and 1.5058 at 20°.

Ethyl Cyanoacetate, $CNCH_2COOC_2H_5$ —**113.11**

[105-56-6]—Colorless to pale yellow liquid. Slightly soluble in water. Miscible with alcohol and with ether. At atmospheric pressure it boils between 205° and 209°, with decomposition. At a pressure of 10 mm of mercury it distills at about 90°.

Specific gravity (841): between 1.057 and 1.062.

Acidity—Dissolve 2 mL in 25 mL of neutralized alcohol, add phenolphthalein TS, and titrate with 0.10 N sodium hydroxide: not more than 1.5 mL is required to produce a pink color.

Ethyl Ether (*Diethyl Ether; Ether*), $(C_2H_5)_2O$ —**74.12** [60-29-7]—Use ACS reagent grade.

Ethyl Ether, Anhydrous (*Diethyl Ether, Anhydrous; Ether, Absolute*), $(C_2H_5)_2O$ —**74.12** [60-29-7]—Use ACS reagent grade.

Ethyl Salicylate, $C_9H_{10}O_3$ —**166.17** [118-61-6]—Colorless liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 10-m capillary column coated with a 1- μ m layer of methylsilicone; the injection port temperature is maintained at 240°; the detector temperature is maintained at 300°; the column temperature is maintained at 150° and programmed to rise 10° per minute to 250°. The area of

the ethyl salicylate peak is not less than 99% of the total peak area.

Refractive index (831): between 1.5216 and 1.5236 at 20°.

2-Ethylaminopropiophenone Hydrochloride, $C_6H_5COCH(CH_3)NHC_2H_5 \cdot HCl$ —**213.70** [51553-17-4]—Use a suitable grade.

4-Ethylbenzaldehyde, $C_2H_5C_6H_4CHO$ —**134.18** [4748-78-1]—Colorless to pale yellow liquid.

Assay—Dissolve about 600 mg, accurately weighed, in a mixture of 100 mL of alcohol and 25 mL of 1 M hydroxylamine hydrochloride in a beaker. Cover the beaker with a watch glass. Heat gently until condensate begins to form on the watch glass. Allow to cool for about 30 minutes. Titrate with 0.5 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.5 N sodium hydroxide is equivalent to 67.09 mg of $C_2H_5C_6H_4CHO$. Not less than 98% is found.

Ethylbenzene, C_8H_{10} —**106.17** [100-41-4]—Not less than 99.5%.

Ethylene Dichloride (1,2-Dichloroethane), $C_2H_4Cl_2$ —**98.96** [107-06-2]—Use ACS reagent grade 1,2-Dichloroethane.

Ethylene Glycol, $HOCH_2CH_2OH$ —**62.07** [107-21-1]—Clear, colorless, slightly viscous, hygroscopic liquid. Slightly soluble in ether; practically insoluble in benzene. Miscible with water and with alcohol.

Specific gravity (841): about 1.11.

Boiling range (Reagent test): between 194° and 200°.

Residue on ignition—Evaporate 100 mL (110 g) in a tared evaporating dish over a flame until the vapors continue to burn after the flame is removed. Allow the vapors to burn until the specimen is consumed. Ignite at $800 \pm 25^\circ$ for 1 hour, cool, and weigh: the residue weighs not more than 5.5 mg (0.005%).

Acidity—Add 0.2 mL of phenol red TS to 50 mL of water, and titrate with 0.1 N sodium hydroxide to a red endpoint. Add 50 mL (55 g) of ethylene glycol, and titrate with 0.1 N sodium hydroxide: not more than 1 mL is required to restore the red color (0.01% as CH_3COOH).

Chloride (Reagent test)—A 4.5-mL (5-g) portion shows not more than 0.025 mg of Cl (5 ppm).

Water, Method I (921): not more than 0.20%.

Ethylene Glycol Monoethyl Ether—See 2-Ethoxyethanol.

Ethylene Oxide in Methylene Chloride (50 mg/mL)—Use a suitable grade.

[NOTE—A suitable grade is available from Sigma Aldrich Corporation, www.sigma-aldrich.com.]

Ethylenediamine (1,2-Diaminoethane) $C_2H_8N_2$ —**60.10** [107-15-3]—Use a suitable grade with a content of not less than 99%.

N-Ethylmaleimide (1-Ethyl-1H-pyrrole 2,5-Dione), $C_6H_7NO_2$ —**125.12** [128-53-0]—Use a suitable grade.

Melting range (741): between 43° and 47°.

2-Ethyl-2-methylsuccinic Acid, $C_7H_{12}O_4$ —**160.17**—White crystals.

Assay—Transfer about 80 mg, accurately weighed, to a suitable beaker, add 30 mL of methanol, and dissolve by stirring. Slowly add 40 mL of deionized water. [NOTE—If cloudiness appears when adding the deionized water, dissolve in 50 mL of methanol only.] When solution is complete, titrate with 0.1 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank titration, and make any necessary correction. Each mL of 0.1 N sodium hydroxide is equivalent to 16.02 mg of $C_7H_{12}O_4$. Not less than 98.5% of $C_7H_{12}O_4$ is found.

Melting point (741): between 101° and 103°.

1-Ethylquinadine Iodide, $C_{12}H_{14}IN$ —**299.15** [606-55-3]—Yellow-green solid. Sparingly soluble in water.

Assay—Dissolve about 290 mg, accurately weighed, in 100 mL of water, and add 10 mL of glacial acetic acid. Titrate with 0.1 N silver nitrate VS, determining the endpoint

potentiometrically, using a silver-ion selective electrode and a calomel reference electrode containing 1 M potassium nitrate. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N silver nitrate is equivalent to 29.92 mg of $C_{12}H_{14}IN$: not less than 97.0% is found.

Factor X_a (Activated Factor X) for Anti-Factor X_a Test—Factor X_a is the proteolytic enzyme derived from bovine plasma, and it cleaves prothrombin to form thrombin. It is a glycoprotein having a molecular weight of 40,000. One Factor X_a Unit is the amount of activated endogenous Factor X (55,000 Da when nonactivated) that is contained in 1 mL of normal plasma. Russell's viper venom is used to activate the enzyme, and is then removed. The preparation is stabilized and lyophilized.

Factor X_a is free of thrombin at the concentration used in the test. When tested against pure fibrinogen, no clotting takes place within 24 hours. It has not less than 40 Factor X_a Units per mg of protein, and exhibits 90% homogeneity when tested by disk electrophoresis.

One Factor X_a Unit per mL gives a 15-second clotting time when tested in the following manner. Mix 0.1 mL of a saturated solution of cephalin (derived from rabbit brain-acetone powder or from an equivalent amount of rabbit brain thromboplastin) in 0.1 mL of citrated bovine plasma and 0.1 mL of 0.025 M calcium chloride. Immediately add 0.1 mL of a solution of factor X_a (1 in 10), and incubate at 37°.

Fast Blue B Salt, $C_{14}H_{12}N_4O_2 \cdot ZnCl_4$ —**475.47** [91-91-8]—Green powder.

Loss on drying (731)—Dry it in vacuum at 110° for 1 hour: it loses not more than 5.0% of its weight.

Absorbance—Dissolve 50 mg in 100 mL of water. In a second container dissolve 100 mg of 2-naphthol in 100 mL of 2-methoxyethanol. Pipet 5 mL of the test solution and 10 mL of the 2-naphthol solution into a 100-mL volumetric flask, and dilute with acetone to volume. For the blank, pipet 5 mL of water and 10 mL of 2-naphthol solution into a second 100-mL volumetric flask, and dilute with acetone to volume. Determine the absorbance of the test solution in a 1-cm cell at the wavelength of maximum absorbance at about 545 nm, with a suitable spectrophotometer, using the blank to set the instrument: the absorbance is not less than 0.80.

Fast Blue BB Salt, $(C_{17}H_{18}ClN_3O_3)_2 \cdot ZnCl_2$ —**831.89** [15710-69-7]—Yellow powder melting at about 162°, with decomposition. Sparingly soluble in water.

Chloride—Transfer about 80 mg, accurately weighed, to a suitable beaker. Add 25 mL of acetone, 25 mL of water, and 500 mg of sodium nitrate. Stir until solution is complete. Titrate with 0.01 N silver nitrate VS, determining the endpoint potentiometrically. Perform a blank determination and make any necessary correction. Not less than 15.0% of chloride is found.

Fast Green FCF, $C_{37}H_{34}N_2Na_2O_{10}S_3$ —**808.86** [2353-45-9]—Red to brown-violet powder or crystals. Soluble in water; sparingly soluble in alcohol. Use a suitable grade.

FD&C Blue No. 1 (Brilliant Blue), $C_{37}H_{34}N_2O_9S_3Na_2$ —**792.86** [3844-45-9]—Use a suitable grade.

Ferric Ammonium Citrate—Thin, transparent, garnet-red scales or granules or brownish-yellow powder. Is deliquescent and is affected by light. Very soluble in water; insoluble in alcohol.

Assay—Accurately weigh about 1 g, dissolve in 25 mL of water in a glass-stoppered flask, add 5 mL of hydrochloric acid and 4 g of potassium iodide, insert the stopper in the flask, and allow to stand in the dark for 15 minutes. Add 100 mL of water, and titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N sodium thiosulfate is equivalent to 5.585 mg of Fe: between 16.5% and 18.5% is found.

Ferric citrate—To 250 mg dissolved in 25 mL of water add 1 mL of potassium ferrocyanide TS: no blue precipitate is formed.

Tartrate—Dissolve 1 g in 10 mL of water, add 1 mL of potassium hydroxide TS, boil to coagulate the ferric hydroxide, adding more potassium hydroxide TS, if necessary, to precipitate all of the iron, filter, and slightly acidify the filtrate with glacial acetic acid. Add 2 mL of glacial acetic acid, and allow to stand for 24 hours: no crystalline white precipitate is formed.

Lead (251)—Dissolve 1.0 g in 30 mL of water, add 5 mL of dilute nitric acid (1 in 21), boil gently for 5 minutes, cool, and dilute with water to 50 mL: 20 mL of the solution shows not more than 0.008 mg of Pb (0.002%).

Ferric Ammonium Sulfate, $\text{FeNH}_4(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ —**482.19**—Use ACS reagent grade.

Ferric Chloride, $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ —**270.29** [10025-77-1]—Use ACS reagent grade.

Ferric Nitrate, $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$ —**404.00** [10421-48-4]—Use ACS reagent grade.

Ferric Sulfate, $\text{Fe}_2(\text{SO}_4)_3 \cdot x\text{H}_2\text{O}$ [10028-22-5]—Grayish-white, hygroscopic powder, or fawn-colored pearls, slowly soluble in water.

Assay—Accurately weigh about 700 mg, and dissolve it in a mixture of 50 mL of water and 3 mL of hydrochloric acid in a glass-stoppered flask. Add 3 g of potassium iodide, and allow to stand in the dark for 30 minutes. Then dilute with 100 mL of water, and titrate with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. Each mL of 0.1 N sodium thiosulfate is equivalent to 5.585 mg of Fe: not less than 21.0% and not more than 23.0% is found.

Insoluble matter (Reagent test)—A 10-g portion, dissolved in a mixture of 100 mL of water and 5 mL of sulfuric acid, shows not more than 2 mg of insoluble matter (0.02%).

Chloride—Dissolve 1 g by warming with a mixture of 10 mL of water and 1 mL of nitric acid, add 4 mL of additional nitric acid, and dilute with water to 50 mL. To 25 mL add 1 mL of phosphoric acid and 1 mL of silver nitrate TS. Any turbidity does not exceed that produced in a control containing 0.01 mg of chloride ion (Cl), 1 mL of nitric acid, 1 mL of phosphoric acid, and 1 mL of silver nitrate TS (0.002%).

Ferrous iron—Dissolve 4 g by warming with 50 mL of dilute sulfuric acid (1 in 10), cool, and titrate with 0.1 N potassium permanganate: not more than 0.16 mL is required to produce a permanent pink color (0.02% as Fe+2). [NOTE—Because the reagents used in the tests for *Copper* and *Zinc* may contain excessive amounts of copper and zinc, they should first be purified by extracting with *Dithizone Extraction Solution* (see *Lead (251)*).]

Copper—Dissolve 1.2 g in 100 mL of water. To 10 mL add 50 mL of a solution containing 5 g of ammonium tartrate and 5 mL of ammonium hydroxide. Add 10 mL of *Standard Dithizone Solution* (see *Lead (251)*), shake for 2 minutes, draw off the dithizone layer, and compare the pink color with that in a control containing 6 µg of copper ion (Cu) and treated exactly as the 10-mL portion of test solution. If the color in the test solution is less than that in the control, then the test specimen contains less than the limit of both *Copper* and *Zinc*. If the color in the test solution is more than that in the control, add 15 mL of dilute hydrochloric acid (1 in 250), and shake for 2 minutes. Draw off the dithizone solution, and shake with a second 15 mL of dilute hydrochloric acid (1 in 250) for 2 minutes. Draw off the dithizone, combine the two acid extracts, and reserve for the *Zinc* test. Any pink color in the dithizone solution is not darker than that in the control solution treated exactly as the test solution (0.005%).

Zinc—To the combined acid extracts saved from the *Copper* test, add 0.5 M sodium acetate to bring the pH between 5.0 and 5.5, and then add 1 mL of 0.1 N sodium thiosulfate. Add 10 mL of *Standard Dithizone Solution* (see *Lead (251)*), shake for 2 minutes, and allow the layers to separate. Draw off the dithizone, and discard the water layer. Any pink color is not greater than that in a control prepared by adding 0.006 mg of zinc ion (Zn) to the combined acid extracts from the control used in the test for *Copper* (0.005%).

Nitrate—Dissolve 10 g in 100 mL of dilute sulfuric acid (1 in 100), heat to boiling, and pour, slowly, into a mixture of 140 mL of water and 50 mL of stronger ammonia TS. Filter through a folded filter while still hot, wash with hot water until the volume of the filtrate is 300 mL, mix, and cool. To 15 mL of this solution add 1 mL of sodium chloride solution (1 in 200), 0.10 mL of indigo carmine TS, and 15 mL of sulfuric acid. The blue color is not completely discharged at the end of 5 minutes (0.01%).

Substances not precipitated by ammonia—Evaporate to dryness 30 mL of the filtrate obtained in the test for *Nitrate*, and ignite gently: the weight of residue does not exceed 1 mg (0.10%).

Ferrocypen (*Dicyano-bis (1,10-phenantroline) iron (II) Complex*), $(\text{C}_{12}\text{H}_8\text{N}_2)_2\text{Fe}(\text{CN})_2$ —**468.3**—Brown to black powder. Dark red solution at 10 mg per mL in glacial acetic acid. Soluble in chloroform and in water at 5 mg per mL, yielding a clear purple solution in chloroform and a clear orange solution in water.

Water, Method I (921): not more than 10%.

Ferrous Ammonium Sulfate, $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$ —**392.14**—Use ACS reagent grade.

Ferrous Sulfate, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ —**278.02** [7782-63-0]—Use ACS reagent grade.

Ferulic Acid (4-Hydroxy-3-methoxycinnamic acid), $\text{C}_{10}\text{H}_{10}\text{O}_4$ —**194.19** [1135-24-6]—Use a suitable grade.

Fibroblast Growth Factor-2—Use a suitable grade.

[NOTE—A suitable grade can be obtained from Roche Diagnostics Corporation, www.rosche-diagnostics.com.]

Filter Paper, Quantitative—For the *Mercuric Bromide Test Paper* used in testing for arsenic, use Swedish O filter paper or other makes of like surface, quality, and ash.

Fluorene, $\text{C}_{13}\text{H}_{10}$ —**166.22** [86-73-7]—White to off-white crystals or powder. Soluble in benzene, in carbon disulfide, in ether, and in hot alcohol; freely soluble in glacial acetic acid.

Solubility test—One g dissolves in 10 mL of acetone to yield a clear and complete solution.

Melting range (741): between 113° and 117°, within a 2° range.

9-Fluorenylmethyl Chloroformate, $\text{C}_{15}\text{H}_{11}\text{ClO}_2$ —**258.70** [28920-43-6]—Clear, colorless solid. Melts at about 62°.

Fluorescamine, $\text{C}_{17}\text{H}_{10}\text{O}_4$ —**278.26** [38183-12-9]—White to off-white powder. Very slightly soluble in water; freely soluble in methylene chloride; soluble in alcohol; slightly soluble in chloroform.

Assay—Dissolve about 600 mg in 75 mL of dimethylformamide, and titrate with 0.1 N lithium methoxide to a blue endpoint, using 1% thymol blue in dimethylformamide as the indicator. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N lithium methoxide is equivalent to 27.83 mg of $\text{C}_{17}\text{H}_{10}\text{O}_4$. Not less than 99% is found.

Loss on drying (731)—Dry it at 105° for 4 hours: it loses not more than 0.5% of its weight.

4'-Fluoroacetophenone, $\text{FC}_6\text{H}_4\text{COCH}_3$ —**138.14** [403-42-9]—Colorless liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 200°; the detector temperature is maintained at 250°; the column temperature is maintained at 100° and programmed to rise 10° per minute to 250°. The area of the $\text{C}_6\text{H}_4\text{COCH}_3$ peak is not less than 99% of the total peak area.

Refractive index (831): 1.510 at 20°.

Formaldehyde Solution, HCHO —(30.03) and water—Use ACS reagent grade.

Formamide, HCONH_2 —45.04 [75-12-7]—Use ACS reagent grade.

Preparation for Digitoxin Assay—To ensure freedom from ammonia, treat Formamide as follows. Shake a suitable quantity of formamide with about 10% of its weight of anhydrous potassium carbonate for 15 minutes, and filter. Distill the filtrate in an all-glass apparatus under vacuum at a pressure of about 25 mm of mercury or less. Reject the first portion of distillate containing water, and collect the fraction that boils at about 115° at a pressure of 25 mm of mercury or at 101° at a pressure of 12 mm of mercury. Store in tight containers, protected from light.

Formamide, Anhydrous, HCONH_2 —45.04 [75-12-7]—Use formamide that has a water content of less than 0.1%.

Formic Acid, HCOOH —46.03 [64-18-6]—Use ACS reagent grade Formic Acid, 88 Percent.

Formic Acid, 96 Percent, HCOOH —46.03 [64-18-6]—Use ACS reagent grade Formic Acid, 96 Percent.

Formic Acid, Anhydrous—Use ACS reagent grade Formic Acid, 96 Percent.

Fuchsin, Basic (*Basic Red 9*, *Parafuchsin Hydrochloride*), $\text{C}_{19}\text{H}_{17}\text{N}_3$ —323.82 [569-61-9]—Use a suitable grade.

Fuller's Earth, Chromatographic—(*Very Fine and Moderately Coarse*)—Gray or grayish-white powder or granules consisting mainly of hydrous aluminum-magnesium silicate.

Powder fineness—See *Powder Fineness* (811).

Soluble matter—Twenty g, treated with 50 mL of cold water and filtered, yields not more than 60 mg of residue upon evaporation of the filtrate (0.3%). A second 20-g portion, treated with 50 mL of cold alcohol and filtered, yields not more than 14 mg upon evaporation of the filtrate (0.07%).

Loss on drying (731)—Dry it at 105° for 6 hours: it loses between 7.0% and 10.0% of its weight.

[NOTE—Adjust the water content, if necessary, by drying in vacuum at room temperature, restoring the water required, and equilibrating by shaking for 2 hours.]

Fuming Nitric Acid—See *Nitric Acid, Fuming*.

Fuming Sulfuric Acid—See *Sulfuric Acid, Fuming*.

Furfural (*2-Furancarboxyaldehyde*; *2-Furaldehyde*), $\text{C}_4\text{H}_3\text{OCHO}$ —96.08 [98-01-1]—Use ACS reagent grade.

G Designations—See phases for gas chromatography under *Reagents, Chromatographic Columns*.

Gadolinium (Gd III) Acetate Hydrate, $(\text{CH}_3\text{CO}_2)_3\text{Gd} \cdot x\text{H}_2\text{O}$ —334.38 [100587-93-7]—White, crystalline, hygroscopic powder. Irritant. Use a suitable grade.

Geneticin (G418; *O*-2-Amino-2,7-dideoxy-*D*-glycero- α -*D*-glucoheptopyranosyl-(1-4)-*O*-(3-deoxy-4-*C*-methyl-3-(methylamino)- β -*D*-arabinopyranosyl-(1-6)-*D*-streptamine), $\text{C}_{20}\text{H}_{40}\text{N}_4\text{O}_{10}$ —496.55 [49863-47-0]—Use a suitable grade, cell culture tested.

Girard Reagent T—See *Trimethylacetylhydrazide Ammonium Chloride*.

Gitoxin, $\text{C}_{41}\text{H}_{64}\text{O}_{14}$ —780.94 [4562-36-1]—White, crystalline powder. Practically insoluble in water, in chloroform, and in ether; slightly soluble in pyridine and in diluted alcohol. Melts at about 250°, with decomposition.

Specific rotation (781): between +3.8° and +4.8°, determined in a solution of pyridine containing 10 mg per mL, with the use of a mercury light at 546.1 nm; between +21° and +25°, determined in a solution of equal parts of chloroform and methanol containing 5 mg per mL, with the use of sodium light.

Suitability—Dissolve 10 mg each of USP Digitoxin RS, previously dried, USP Digoxin RS, previously dried, and gitoxin, respectively, in separate 5-mL portions of a mixture of 2 parts of chloroform and 1 part of methanol, and dilute each with additional solvent mixture to 10 mL. Then proceed as directed in the *Identification test* under *Digoxin*. The chromatogram of gitoxin shows one fluorescent spot, located between the digoxin and digitoxin spots.

Glacial Acetic Acid—See *Acetic Acid, Glacial*.

Glass Wool—Fine threads of glass.

Acid-soluble substances—Boil 1 g for 30 minutes with 30 mL of diluted hydrochloric acid, and filter. Evaporate the filtrate, and dry the residue at 105° to constant weight: the residue weighs not more than 5 mg (0.5%).

Heavy metals—Boil 2 g with a mixture of 25 mL each of diluted nitric acid and water for 5 minutes, and filter. Evaporate one-half of the filtrate to dryness, dissolve the residue in 10 mL of water to which 3 drops of hydrochloric acid have been added, filter if necessary, and add an equal volume of hydrogen sulfide TS to the filtrate: no darkening is produced.

D-Gluconic Acid, 50 Percent in Water, $\text{C}_6\text{H}_{12}\text{O}_7$ —196.16 [526-95-4]—Pale yellow liquid.

Assay—Dilute about 200 mg of the solution, accurately weighed, with 30 mL of water. Titrate with 0.1 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination and make any necessary correction. Each mL of 0.1 N sodium hydroxide is equivalent to 19.62 mg of $\text{C}_6\text{H}_{12}\text{O}_7$. Not less than 49.0% is found.

Refractive index (831): between 1.4160 and 1.4180 at 20°.

Specific rotation (781): between +9.9° and +11.9°, determined as is, at 20°.

Glucose, $\text{C}_6\text{H}_{12}\text{O}_6$ —180.2 [50-99-7]—Use a suitable grade. A white, crystalline powder. Freely soluble in water; sparingly soluble in alcohol.

D-Glucuronolactone, $\text{C}_6\text{H}_8\text{O}_6$ —176.12 [32449-92-6]—Use a suitable grade.

Glutamic Acid, $\text{C}_5\text{H}_9\text{NO}_4$ —147.13 [56-86-0]—Use a suitable grade.

L-Glutamic Acid, $\text{C}_5\text{H}_9\text{NO}_4$ —147.1 [56-86-0]—White powder or white powder with a faint yellow cast. Use a suitable grade.

L-Glutamine, $\text{C}_5\text{H}_{10}\text{N}_2\text{O}_3$ —146.15 [56-85-9]—White, crystalline powder. Use a suitable grade.

Glycerin (*Glycerol*) [56-81-5]—Use ACS reagent grade Glycerol.

Glycolic Acid, $\text{C}_2\text{H}_4\text{O}_3$ —76.05 [79-14-1]—White crystalline powder or chunks.

Assay—

SILYLATING REAGENT: Pyridine, hexamethyldisilazane, chlorotrimethylsilane (9:3:1)

SAMPLE PREPARATION: Weigh approximately 25 mg (about 3 drops) of the sample into a test tube. Add 2 mL of the *Silylating reagent* and cap the test tube. Mix well and allow to incubate at room temperature for a minimum of 2 h. A white precipitate of ammonium chloride will form. Centrifuge and use the clear supernatant for injection.

PROCEDURE: Inject an appropriate volume of the *Sample preparation* into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2. The injection port temperature is maintained at 250°; the detector temperature is maintained at 300°; the column temperature is main-

tained at 100° and programmed to rise 10° per min to 250°. The area of the peak corresponding to $C_2H_4O_3$ is NLT 98.5% of the total peak area.

Gold Chloride (*Chlorauric Acid*), $HAuCl_4 \cdot 3H_2O$ —**393.83** [16903-35-8]—Use ACS reagent grade.

Guaiaol (*o*-Methoxyphenol), $C_7H_8O_2$ —**124.14** [95-05-1]—Colorless to yellowish, refractive liquid. Soluble in about 65 parts of water; soluble in sodium hydroxide solution; miscible with alcohol, with chloroform, with ether, and with glacial acetic acid.

Assay—When examined by gas-liquid chromatography, it shows a purity of not less than 98%. The following conditions have been found suitable for assaying it: a 3-mm \times 1.8-m stainless steel column containing liquid phase G16 on 60- to 80-mesh support S1A. Helium is the carrier gas, the injection port temperature is maintained at 180°, the column temperature is maintained at 200°, and the flame-ionization detector is maintained at 280°. The retention time is about 8 minutes.

Refractive index (831): between 1.5430 and 1.5450, at 20°.

Guanidine Hydrochloride, (*Aminoformamidinium Hydrochloride*; *Aminomethanamidinium Hydrochloride*), $CH_5N_3 \cdot HCl$ —**95.53** [50-01-1]—White, crystalline powder. Freely soluble in water and in alcohol. Use a suitable grade with a content not less than 99%.

Guanidine Isothiocyanate, $C_2H_6N_4S$ —**118.2** [593-84-0]—White powder or colorless crystals. Use a suitable grade.

Guanine Hydrochloride, $C_5H_5N_5O \cdot HCl \cdot H_2O$ —**205.60** [635-39-2]—White, crystalline powder. Melts above 250°, with decomposition. Slightly soluble in water and in alcohol; soluble in acidulated water and in sodium hydroxide TS. Its solutions are not precipitated by iodine TS or by mercuric-potassium iodide TS, but form a precipitate with trinitrophenol TS.

Residue on ignition (Reagent test): negligible, from 100 mg.

Loss on drying (731)—Dry it at 105° to constant weight: it loses not more than 10.0% of its weight.

Hematein, $C_{16}H_{12}O_6$ —**300.26** [475-25-2]—Prepared from logwood extract or from hematoxylin by treatment with ammonia and exposure to air. Reddish-brown crystals with a yellowish-green metallic luster. Very slightly soluble in water (about 1 in 1700); slightly soluble in alcohol and in ether; insoluble in benzene and in chloroform; freely soluble in diluted ammonia solution to form a solution of dusky purplish-red color and in an aqueous solution of sodium hydroxide (1 in 50), to form a solution of bright red color, viewed in each case through a layer 1 cm in depth. Melts at a temperature above 200° and tends to decompose at 250°.

Hematoxylin (*Hydroxybrasilin*), $C_{16}H_{14}O_6 \cdot 3H_2O$ —**356.32** [517-28-2]—A crystalline substance derived from the heartwood of *Haematoxylon campechianum* Linné (Fam. Leguminosae). Colorless to yellow prisms. Very slightly soluble in cold water and in ether; rapidly soluble in hot water and in hot alcohol. When exposed to light, it acquires a red color and yields a yellow solution. Dissolves in ammonia TS and in solutions of alkali hydroxides and carbonates. When dissolved in solutions of the following salts, it develops the colors indicated: in alum solution, a red color; in stannous chloride solution, a rose color; and in solutions of cupric salts, a greenish-gray color. It gradually turns black in potassium dichromate solution. Store hematoxylin and its solutions protected from light and air.

Hemoglobin, Bovine [9008-02-0]—Use a suitable grade.

[NOTE—A suitable grade is available as Bovine Hemoglobin substrate powder from Sigma-Aldrich, www.sigma-aldrich.com.]

1-Heptadecanol, $C_{17}H_{36}O$ —**256.48** [1454-85-9]—Use a suitable grade.

Heptafluorobutyric Acid, $C_4F_7O_2H$ —**214.04** [375-22-4]—Use a suitable grade.

Heptakis-(2,6-di-O-methyl)- β -cyclodextrin (*2,6-Di-O-methyl- β -cyclodextrin*; *Dimethyl- β -cyclodextrin*) $C_{56}H_{98}O_{35}$ —**1331.36** [51166-71-3]—Use a suitable grade.

n-Heptane—Use *n-Heptane*, *Chromatographic*.

n-Heptane, Chromatographic C_7H_{16} —**100.21** [142-82-5]—Clear, colorless, volatile, flammable liquid consisting essentially of C_7H_{16} . Practically insoluble in water; soluble in absolute alcohol. Miscible with ether, with chloroform, with benzene, and with most fixed and volatile oils. Use a suitable grade, chromatographic or HPLC, with a content of not less than 99%.

Heptyl p-Hydroxybenzoate (*Heptyl 4-Hydroxybenzoate*; *N-Heptyl 4-Hydroxybenzoate*; *Benzoic Acid, 4-Hydroxy-, Heptyl Ester*), $C_{14}H_{20}O_3$ —**236.31** [1085-12-7]—Use a suitable grade with a content of NLT 98%.

Hexadecyl Hexadecanoate (*Hexadecyl Palmitate*; *Cetyl Palmitate*), $C_{32}H_{64}O_2$ —**480.85** [540-10-3]—Use a suitable grade.

[NOTE—Suitable grades are available commercially as Hexadecyl Palmitate and Palmitic Acid Palmityl Ester from Sigma-Aldrich, www.sigma-aldrich.com, and Cetyl Palmitate, Catalog number C1203, from Spectrum Chemical Mfg. Corp., www.spectrumchemical.com.]

Hexadecyltrimethylammonium Bromide—See *Cetyltrimethylammonium Bromide*.

Hexadimethrine Bromide, $(C_{13}H_{30}Br_2N_2)_n$ [28728-55-4]—White to off-white powder, hygroscopic, amorphous polymer. Soluble in water up to 10% to give a colorless to light yellow solution. Use a suitable grade.

Hexamethyldisilazane, $C_6H_{19}NSi_2$ —**161.39** [999-97-3]—Clear, colorless liquid.

Assay—When examined by gas-liquid chromatography, it shows a purity of not less than 95%. The following conditions have been found suitable for assaying the article: A 2-mm \times 1.8-m glass column packed with phase G3 on support S1. Helium, flowing at a rate of about 40 mL per minute, is the carrier gas; the detector temperature is about 310°; the injection port temperature is about 100°; and the column temperature is programmed to start at 35°, hold for 5 minutes, then rise at a rate of 8° per minute to 200°. A flame-ionization detector is employed.

Residue after evaporation—Transfer 200 g to a tared dish, and evaporate on a steam bath to dryness. Dry the residue at 105° for 1 hour, cool, and weigh: not more than 0.0025% of residue is found.

Hexamethyleneimine (*Homopiperidine*), $C_6H_{12}NH$ —**99.17** [111-49-9]—Colorless to nearly colorless liquid.

Refractive index (831): between 1.4640 and 1.4660 at 20°.

Hexamethylenetetramine—See *Methenamine*.

n-Hexane, C_6H_{14} —**86.18** [110-54-3] (for use in spectrophotometry)—Use *Hexanes*.

Hexane, Solvent (*Petroleum Benzin*; *Petroleum Ether*, *Ligroin*) [8032-32-4]—Clear, volatile liquid. Practically insoluble in water; soluble in absolute alcohol. Miscible with ether, with chloroform, with benzene, and with most fixed and volatile oils.

[CAUTION—It is dangerously flammable. Keep it away from flames, and store in tight containers in a cool place.]

Use ACS reagent grade Petroleum Ether.

Hexane, Solvent, Chromatographic—Use ACS HPLC reagent grade.

Hexanes (suitable for use in UV spectrophotometry); usually a mixture of several isomers of hexane (C_6H_{14}), predomi-

nantly *n*-hexane, and methylcyclopentane (C_6H_{12})—Use ACS spectrophotometric reagent grade.

Hexanitrodiphenylamine (*Dipicrylamine*), $C_{12}H_5N_7O_{12}$ —**439.21** [131-73-7]—Yellow-gold powder or prisms. *Explosive*. Usually contains about 15% of water as a safety precaution. Insoluble in water, in alcohol, in acetone, and in ether; soluble in glacial acetic acid and in alkalis.

Water, Method I (921): not more than 16%.

Hexanophenone, $C_{12}H_{16}O$ —**176.25** [942-92-7]—Yellow liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G3; the injection port temperature is maintained at 280°; the detector temperature is maintained at 300°; the column temperature is maintained at 180° and programmed to rise 10° per minute to 280°. The area of the $C_{12}H_{16}O$ peak is not less than 98% of the total peak area.

Refractive index (831): 1.511 ± 0.002 at 20°.

Hexylamine (*1-Aminohexane*), $C_6H_{15}N$ —**101.19** [111-26-2]—Use a suitable grade with a content of not less than 99%.

Histamine Dihydrochloride, $C_5H_9N_3 \cdot 2HCl$ —**184.07**—Use USP Histamine Dihydrochloride RS.

L-Histidine Hydrochloride Monohydrate, $C_6H_9N_3O_2 \cdot HCl \cdot H_2O$ —**209.63** [5934-29-2]—Use a suitable grade.

Horseradish Peroxidase Conjugated to Goat Anti-Mouse IgG—Affinity purified polyclonal antibody to Mouse Immune globulin (IgG) heavy and light chains (whole IgG) produced in Goat and labeled with horseradish peroxidase. Available either as a lyophilized powder or as a solution in a suitable buffer, generally 10 mM sodium phosphate, pH 7.4, containing a suitable preservative, such as 0.01% thimerosal, and an inactive protein(s) to prevent adsorption on the surface of the container. Use a suitable grade. Store at -20°.

Hydrazine Dihydrochloride, $(NH_2)_2 \cdot 2HCl$ —**104.97** [5341-61-7]—White powder.

Assay—Dissolve about 34 mg, accurately weighed, in 50 mL of water. Add carefully while stirring, 1 g of sodium bicarbonate. [CAUTION—There may be a rapid evolution of carbon dioxide.] Titrate with 0.1 N iodine solution, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary corrections. Each mL of 0.1 N iodine solution is equivalent to 2.63 mg of $(NH_2)_2 \cdot 2HCl$. Not less than 98% is found.

Hydrazine Hydrate, 85% in Water, $(NH_2)_2 \cdot H_2O$ —**50.06** [7803-57-8]—Colorless liquid.

Assay—Transfer 600 mg, accurately weighed, to a 100-mL volumetric flask. Dilute with water to volume, and mix. Pipet 10 mL into a suitable beaker, and add 1.0 g of sodium bicarbonate and 50.0 mL of 0.1 N iodine VS. Titrate the excess iodine with 0.1 N sodium thiosulfate VS, using starch TS as the indicator. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N iodine is equivalent to 1.252 mg of $(NH_2)_2 \cdot H_2O$. Not less than 83% is found.

Hydrazine Sulfate, $(NH_2)_2 \cdot H_2SO_4$ —**130.12** [10034-93-2]—Use ACS reagent grade. [CAUTION—Great care should be taken in handling hydrazine sulfate because it is a suspected carcinogen.]

Hydrindantin (*2,2'-Dihydroxy-2,2'-biindan-1,1',3,3'-tetraone*), $C_{18}H_{10}O_6$ —**322.27** [5103-42-4]—Sparingly soluble in hot water; soluble in methoxyethanol. When heated above 200°, it becomes reddish brown.

Melting range (741): between 249° and 254°.

Hydriodic Acid, HI—**127.91** [10034-85-2]—Use ACS reagent grade (containing not less than 47.0% of HI).

[NOTE—For methoxy determination (see *Methoxy Determination* (431)), use hydriodic acid ACS reagent grade 55%.

Use this grade also for alkoxyl determinations in assays in the individual monographs.]

Hydrobromic Acid, HBr—**80.91** [10035-10-6]—Use ACS reagent grade.

Hydrochloric Acid, HCl—**36.46** [7647-01-0]—Use ACS reagent grade.

Hydrochloric Acid, Diluted (10 percent) [7647-01-0]—Prepare by mixing 226 mL of hydrochloric acid with sufficient water to make 1000 mL.

Hydrofluoric Acid, HF—**20.01** [7664-39-3]—Use ACS reagent grade.

Hydrogen Peroxide, H_2O_2 —**34.01** [7722-84-1]—Use ACS reagent grade with an assay content between 29.0% and 32.0%.

Hydrogen Peroxide, 10 Percent, H_2O_2 —**34.01**—Dilute 30 mL of 30 percent hydrogen peroxide with water to 100 mL.

Hydrogen Peroxide, 30 Percent, Unstabilized H_2O_2 —**34.01** [7722-84-1]—Use ACS reagent grade, with an assay content between 29.0% and 32.0%, without an added stabilizer.

Hydrogen Peroxide, 50 Percent in Water, H_2O_2 —**34.01** [7722-84-1]—Use a suitable grade.

Hydrogen Peroxide Solution—Use *Hydrogen Peroxide Topical Solution*.

Hydrogen Sulfide, H_2S —**34.08** [7783-06-4]—Colorless, poisonous gas, heavier than air. Soluble in water. Is generated by treating ferrous sulfide with diluted sulfuric or diluted hydrochloric acid. Other sulfides yielding hydrogen sulfide with diluted acids may be used. Is also available in compressed form in cylinders.

Hydrogen Sulfide Detector Tube—A fuse-sealed glass tube so designed that gas may be passed through it and containing suitable absorbing filters and support media for the indicator, the latter consisting of a suitable lead salt.

Measuring range: 1 to 20 ppm.

[NOTE—Available from Draeger Safety, Inc., www.draeger.com, or from Gastec Corp., www.gastec.co.jp, distributed in the USA by www.nextteq.com.]

Hydroquinone, $C_6H_4(OH)_2$ —**110.11** [123-31-9]—Fine, colorless or white, needle crystals. Darkens on exposure to air and light. Soluble in water, in alcohol, and in ether.

Assay—Accurately weigh about 250 mg, and dissolve in a mixture of 100 mL of water and 10 mL of 0.1 N sulfuric acid in a 250-mL conical flask. Add 3 drops of a 1 in 100 solution of diphenylamine in sulfuric acid, and titrate with 0.1 N ceric sulfate VS until the solution is red-violet in color. Each mL of 0.1 N ceric sulfate is equivalent to 5.506 mg of $C_6H_4(OH)_2$. Not less than 99% is found.

Melting range (741): between 172° and 174°.

Hydroxy Naphthol Blue (*1-(2-Naphtholazo-3,6-disulfonic Acid)-2-naphthol-4-sulfonic Acid, Disodium Salt*), $C_{20}H_{12}N_2O_{11}S_3Na_2$ —**598.50** [165660-27-5]—Deposited on crystals of sodium chloride in the concentration of about 1%. Use ACS reagent grade.

3'-Hydroxyacetophenone, $C_8H_8O_2$ —**136.15** [121-71-1]—Light brown powder chips and chunks. Melts at about 96°. Sparingly soluble in chloroform, yielding a clear, light yellow solution.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with G1; the detector and the injection port temperatures are maintained at 300°; the column temperature is maintained at 180° and programmed to rise 10° per minute to 280° and held at that temperature for 10 minutes. The area of the main peak is not less than 97% of the total peak area.

4'-Hydroxyacetophenone, $HOC_6H_4COCH_3$ —**136.15** [99-93-4]—Gray powder, melting at about 109°.

p-Hydroxybenzoic Acid, $C_7H_6O_3$ —**138.12** [99-96-7]—White crystals.

Assay—Transfer about 700 mg, accurately weighed, to a suitable container, and dissolve in 50 mL of acetone. Add 100 mL of water, mix, and titrate with 0.5 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.5 N sodium hydroxide is equivalent to 69.06 mg of $C_7H_6O_3$; not less than 97% is found.

Melting range (741): over a range of 2° that includes 216°.

4-Hydroxybenzoic Acid Isopropyl Ester, $HOC_6H_4COOCH(CH_3)_2$ —**180.18** [4191-73-5]—Use a suitable grade.

[NOTE—A suitable grade is available from TCI America, www.tciamerica.com.]

Melting range (741): between 84° and 87°.

2-Hydroxybenzyl Alcohol, $C_7H_8O_2$ —**124.14** [90-01-7]—Off-white flakes. Very soluble in alcohol, in chloroform, and in ether; soluble in 15 parts water and in benzene.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)), equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 250°; the detector temperature is maintained at 300°; and the column temperature is maintained at 150° and programmed to rise 10° per minute to 280°. The area of the $C_7H_8O_2$ peak is not less than 99% of the total peak area.

Melting range (741): between 83° and 85°.

4-Hydroxybutane-1-sulfonic Acid (4-Hydroxy-1-butanefulfonic Acid), $C_4H_{10}O_4S$ —**154.19** [26978-64-3]—Use a suitable grade with a content of NLT 95%. [NOTE—A suitable grade is available as catalog number RM-967-C50 from www.cydexpharma.com.]

N-(2-Hydroxyethyl)piperazine-N'-(2-ethanesulfonic acid), $C_8H_{18}N_2O_4S$ —**238.3** [7365-45-9]—Use a suitable grade.

Hydroxylamine Hydrochloride, $NH_2OH \cdot HCl$ —**69.49** [5470-11-1]—Use ACS reagent grade.

10 β -Hydroxynorandrostenedione (10 β -Hydroxy-19-norandrost-4-ene-3,17-dione), $C_{18}H_{24}O_3$ —**288.38**—Use a suitable grade.

4-(4-Hydroxyphenyl)-2-butanone, $C_{10}H_{12}O_2$ —**164.20** [5471-51-2]—White powder.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G43; the injection port temperature is maintained at 280°; the detector temperature is maintained at 300°; the column temperature is maintained at 180° and programmed to rise 10° per minute to 280°. The area of the $C_{10}H_{12}O_2$ peak is not less than 98.5% of the total peak area.

Melting range (741): between 81° and 87°.

3-Hydroxyphenyldimethylethyl Ammonium Chloride [Dimethylethyl(3-hydroxyphenyl)ammonium Chloride]—Use Edrophonium Chloride.

D- α -4-Hydroxyphenylglycine, $C_8H_9NO_3$ —**167.16** [22818-40-2]—Shiny leaflets. Sparingly soluble in water, in alcohol, in acetone, in ether, in chloroform, in ethyl acetate, in benzene, and in glacial acetic acid; soluble in alkalis and in mineral acids; freely soluble in warm 20% v/v hydrochloric acid.

Melting range (741): between 220° and 247°, with decomposition.

2'-(4-Hydroxyphenyl)-5-(4-methyl-1-piperazinyl)-2,5'-bi-1H-benzimidazole Trihydrochloride Pentahydrate—**623.97** [23491-44-3]—Dark yellow to tan powder with a green cast. Use a suitable grade.

Hydroxypropyl- β -cyclodextrin (Hydroxypropylbetadex), $C_{42}H_{70}O_{35}(C_3H_6O)_x$ with $x = 7$ molar substitution

[94035-02-6]—Use a suitable grade with a substitution degree between 0.40 and 1.50.

8-Hydroxyquinoline (Oxine), C_9H_7NO —**145.16**

[148-24-3]—Use ACS reagent grade 8-Quinolinol.

Hypophosphorous Acid, 50 Percent (Hypophosphorous Acid), HPH_2O_2 —**66.00** [6303-21-5]—A colorless to faintly yellow liquid. Miscible with water and with alcohol.

Assay—Accurately weigh about 4 mL, dilute with 25 mL of water, add methyl red TS, and titrate with 1 N sodium hydroxide VS: each mL of 1 N sodium hydroxide is equivalent to 66.00 mg of HPH_2O_2 . Not less than 48% is found.

Chloride—Add 0.2 mL to a mixture of 10 mL of silver nitrate TS and 5 mL of nitric acid, and heat until brown fumes are no longer evolved: any white, insoluble residue remaining is negligible.

Phosphate—Dilute 1 mL with water to 50 mL, render alkaline with ammonia TS, filter if a precipitate is formed, and add to the filtrate 5 mL of magnesia mixture TS: not more than a slight precipitate is formed within 5 minutes.

Sulfate (Reagent test, *Method I*)—Dilute 1 mL with water to 50 mL: 20 mL of the solution shows not more than 0.2 mg of SO_4 .

Hypoxanthine, $C_5H_4N_4O$ —**136.11** [68-94-0]—White to yellowish-white powder. Soluble in 1 N sodium hydroxide. Use a suitable grade.

IgG-Coated Red Cells—Red cells coated with human immunoglobulin (IgG). The reagent must be obtained from manufacturers or suppliers licensed by the Center for Biologics Evaluation and Research, Food and Drug Administration. The use of reagents from an unlicensed manufacturer or supplier may invalidate the results.

[NOTE—There are many manufacturers and suppliers of these reagents that are licensed by the Center for Biologics Evaluation and Research, Food and Drug Administration. Some examples of licensed manufacturers or suppliers are the following: Gamma Biologics, Houston, TX; and Ortho Diagnostics, Raritan, NJ.]

Imidazole, $C_3H_4N_2$ —**68.08** [288-32-4]—White to light yellow crystals. Freely soluble in water. Use ACS reagent grade.

Indene, C_9H_8 —**116.16** [95-13-6]—Colorless liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 10-m capillary column coated with a 1- μ m layer of methylsilicone; the injection port temperature is maintained at 200°; the detector temperature is maintained at 300°; the column temperature is maintained at 100° and programmed to rise 10° per minute to 250°. The area of the indene peak is not less than 99% of the total peak area.

Refractive index (831): between 1.5749 and 1.5769 at 20°.

Indicators—See separate subsection.

Indigo Carmine—Use Indigotindisulfonate Sodium.

Indole (2,3-Benzopyrrole), C_8H_7N —**117.14**

[120-72-9]—Use a suitable grade.

Indole-3-carboxylic Acid, $C_9H_7NO_2$ —**161.2**

[771-50-6]—Use a suitable grade.

Inosine, $C_{10}H_{12}N_4O_5$ —**268.23** [58-63-9]—White, crystalline powder.

Melting point (741): about 90°.

Inositol (Hexahydroxycyclohexane), $C_6H_6(OH)_6$ —**180.16** [87-89-8]—Fine, white crystals or a white, crystalline powder; stable in air. Its solutions are neutral to litmus. Optically inactive. One g dissolves in 5.7 mL of water. Slightly soluble in alcohol; insoluble in ether and in chloroform. Store in well-closed containers.

Melting range (741): between 223° and 226°.

Loss on drying (731)—Dry it at 105° for 4 hours: it loses not more than 0.5% of its weight.

Residue on ignition (Reagent test): not more than 0.1%.

Iobenguane Sulfate (*m*-Iodobenzylguanidine Hemisulfate Salt), $C_8H_{10}IN_3 \cdot \frac{1}{2}H_2SO_4$ —**324.1**—White powder. Freely soluble in methanol.

Assay—When tested by thin-layer chromatography, with the use of plates coated with chromatographic silica gel mixture, a developing system consisting of a mixture of butyl alcohol, water, and acetic acid (60:25:15), and examined under short-wavelength UV light, not more than a single impurity spot of not more than 0.5% is observed.

Iodic Acid, HIO_3 —**175.91** [7782-68-5]—Use ACS reagent grade.

Iodine, I_2 —**253.81** [7553-56-2]—Use ACS reagent grade.

Iodine Monobromide, IBr —**206.81** [7789-33-5]—Black, gray, or blue-purple crystals, crystalline needles, or crystalline chunks.

Assay—Place about 100 mL of acetic acid in a 150-mL beaker. Separately dissolve 2 g of potassium iodide in a minimum volume of water, add this solution to the acetic acid, and mix. Transfer about 200 mg of Iodine Monobromide, accurately weighed, to the beaker containing the potassium iodide and acetic acid mixture, and stir to dissolve. Titrate immediately with 0.1 N sodium thiosulfate VS, determining the endpoint potentiometrically (see *Titrimetry* (541)). Perform a blank determination, and make any necessary correction. Each mL of 0.1 N sodium thiosulfate is equivalent to 20.681 mg of IBr . Not less than 97.5% is found.

Iodine Monochloride, ICl —**162.36** [7790-99-0]—Use ACS reagent grade.

Iodoethane, C_2H_5I —**155.9** [75-03-6]—Use a suitable grade.

p-Iodonitrotetrazolium Violet, (2-(4-Iodophenyl)-3-(4-nitrophenyl)-5-phenyltetrazolium chloride), $C_{19}H_{13}ClIN_5O_2$ —**505.70**—Light yellow powder.

Assay—When tested by thin-layer chromatography, with the use of plates coated with chromatographic silica gel mixture and a developing system consisting of a mixture of amyl alcohol, formic acid, and water (8:1:1), sprayed with 0.1% sodium thiosulfate solution, and examined under short-wavelength UV light, a single spot is exhibited, with trace impurities.

Melting point (741): 240°, with decomposition.

Ion-Exchange Resin—An intimate mixture of 4 parts of a strongly acidic cation-exchanger in the hydrogen form (produced by sulfonation of a styrene-divinylbenzene copolymer, representing 8 to 10% divinylbenzene) and 6 parts of a strongly basic anion-exchanger in the hydroxyl form (produced by amination with trimethylamine of a chloromethylated styrene-divinylbenzene copolymer, representing 3 to 5% divinylbenzene).

[NOTE—A suitable resin is “Amberlite MB-150,” available from Sigma-Aldrich, www.sigma-aldrich.com.]

Iron Wire, Fe—**At. Wt. 55.847**—Use a suitable grade.

Isoamyl Alcohol—Use *Amyl Alcohol*.

Isobutyl Acetate, $C_6H_{12}O_2$ —**116.16** [110-19-0]—Clear, colorless liquid. Slightly soluble in water. Miscible with alcohol.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with G2. The injection port temperature is maintained at 130°; the column temperature is maintained at 30° and programmed to rise 10° per minute to 180° and held there for 10 minutes. The detector temperature is maintained at 300°. The area of the main peak is not less than 99% of the total peak area.

Specific gravity (841): between 0.863 and 0.868.

Refractive index (831): between 1.3900 and 1.3920 at 20°.

Isobutyl Alcohol (2-Methyl-1-propanol), $(CH_3)_2CHCH_2OH$ —**74.12** [78-83-1]—Use ACS reagent grade.

4-Isobutylacetophenone, $C_{12}H_{16}O$ —**176**—Pale yellow liquid. Soluble in chloroform, in glycerols, in alcohols, in ether, and in fatty oils; insoluble in water. Use a suitable grade.

[NOTE—A suitable grade is available from TCI America, www.tciamerica.com.]

N-Isobutylpiperidone, $C_9H_{17}NO$ —**155.24**—Use a suitable grade.

Isoflupredone Acetate (9- α -Fluoroprednisolone Acetate), $C_{23}H_{29}FO_6$ —**420.47**—Use Isoflupredone Acetate USP.

Isomaltotriose (α -D-Glucosyl-(1-6)- α -D-glucosyl-(1-6)- α -D-glucose), $C_{18}H_{32}O_{16}$ —**504.4** [3371-50-4]—White lyophilized powder. Use a suitable grade.

Isonicotinic Acid, $C_6H_5NO_2$ —**123.11** [52-22-1]—Use a suitable grade.

Isonicotinic Acid Hydrazide—Use *Isoniazid*.

Isooctane—See 2,2,4-Trimethylpentane.

Isopropyl Acetate, $C_5H_{10}O_2$ —**102.13** [108-21-4]—Use a suitable grade.

Isopropyl Alcohol (2-Propanol), $(CH_3)_2CHOH$ —**60.10** [67-63-0]—Use ACS reagent grade.

[NOTE—For use in assays and tests involving UV spectrophotometry, use ACS reagent grade Isopropyl Alcohol Suitable for Use in UV Spectrophotometry.]

Isopropyl Alcohol, Dehydrated [67-63-0]—Use Isopropyl Alcohol that previously has been dried by being shaken with a suitable molecular sieve capable of adsorbing water, and filtered.

Isopropyl Ether—See *Diisopropyl Ether*.

Isopropyl Iodide (2-Iodopropane), C_3H_7I —**169.99** [75-30-9]—Use a suitable grade.

Isopropyl Myristate, $C_{17}H_{34}O_2$ —**270.45** [110-27-0]—Use *Isopropyl Myristate* (NF monograph). For use as a solvent in sterility test procedures, Isopropyl Myristate conforms to the following additional specification:

pH of water extract—Transfer 100 mL to a 250-mL centrifuge bottle, add 10 mL of twice-distilled water, close the bottle with a suitable closure, and shake vigorously for 60 minutes. Centrifuge the mixture at 1800 rpm for 20 minutes, aspirate the upper (isopropyl myristate) layer, and determine the pH of the residual water layer: the pH is not less than 6.5.

Isopropyl Myristate not conforming to the test for *pH of water extract* may be rendered suitable for use in sterility test procedures as follows:

Using a 20-mm \times 20-cm glass column, add activated alumina, and tamp down to a height of 15 cm. Pass 500 mL of the isopropyl myristate through the column, using a slight positive pressure to maintain an even flow, and use the eluate collected directly in the sterility test procedure.

Isopropyl Salicylate, $C_6H_4OHCOOCH(CH_3)_2$ —**180.20**—Colorless liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 2-mm \times 1.8-m glass column packed with 7% phase G2 on support S1A; the injection port temperature is maintained at 250°; the detector temperature is maintained at 310°; the column temperature is maintained at 50° and programmed to rise 10° per minute to 250°. The area of the main peak is not less than 97% of the total peak area.

Isopropylamine (2-Aminopropane), $C_3H_7NH_2$ —**59.11** [75-31-0]—Clear, colorless, flammable liquid. Miscible with water, with alcohol, and with ether.

Assay—Transfer about 0.2 g, accurately weighed, to a suitable container, add 50 mL of water, and mix. Titrate with 0.1 N hydrochloric acid VS, using a mixture of bromocresol green TS and methyl red TS (5:1) as indicator. Each

mL of 0.1 N hydrochloric acid is equivalent to 59.11 mg of C_3H_9N . Not less than 98% is found.

Boiling range (Reagent test)—Not less than 95% distills between 31° and 33°.

Refractive index (831): between 1.3743 and 1.3753, at 20°.

Isorhamnetin, $C_{16}H_{12}O_7$ —**316.27** [418-19-3]—Yellow powder.

Melting point: greater than 300°.

Isovaleric Acid (3-Methylbutanoic Acid, Isovaleric Acid, Isopropylacetic Acid), $C_5H_{10}O_2$ —**102.13** [503-74-2]—Use a suitable grade.

Kaempferol, $C_{15}H_{10}O_6$ —**286.24** [520-18-3]—Light yellow to yellow powder. It is a clear, bright yellow solution in alcohol.

Kerosene [8008-20-6]—A mixture of hydrocarbons, chiefly of the methane series. A clear, colorless liquid. Specific gravity: about 0.80. Distills between 180° and 300°.

L Designations—See packings for high-pressure liquid chromatography under *Reagents, Chromatographic Columns*.

Lactose, $C_{12}H_{22}O_{11} \cdot H_2O$ —**360.31** [64-42-3]—Use ACS reagent grade.

Alpha Lactose Monohydrate (α -D-Lactose Monohydrate), $C_{12}H_{22}O_{11} \cdot H_2O$ —**360.31**—White powder. The β -D-lactose content is less than 3%.

Assay—Inject an appropriate derivatized specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 250°; the detector temperature is maintained at 280°; the column temperature is maintained at 230° and programmed to rise 4° per minute to 280°. The area of the $C_{12}H_{22}O_{11} \cdot H_2O$ peak is not less than 97% of the total peak area.

Beta Lactose (β -D-Lactose), $C_{12}H_{22}O_{11}$ —**342.30**—White to faint yellow powder. The α -D-lactose content is not more than 35%.

Assay—Inject an appropriate derivatized specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G43; the injection port temperature is maintained at 250°; the detector temperature is maintained at 250°; the column temperature is maintained at 20° and programmed to rise 8° per minute to 280°. The area of the $C_{12}H_{22}O_{11}$ peak is not less than 99% of the total peak area.

Lanthanum Alizarin Complexan Mixture—Use a suitable grade.

Lanthanum Chloride, $LaCl_3 \cdot (6-7)H_2O$ [10025-84-0]—This reagent is available in degrees of hydration ranging from 6 to 7 molecules of water. Use ACS reagent grade.

Lanthanum Nitrate Hexahydrate, $La(NO_3)_3 \cdot 6H_2O$ —**433.01** [10277-43-7]—Use a suitable grade with a content of NLT 99.9%.

Lanthanum Oxide, La_2O_3 —**325.82** [1312-81-8]—An almost white, amorphous powder, practically insoluble in water. It dissolves in dilute solutions of mineral acids and absorbs atmospheric carbon dioxide. Use Atomic Absorption Spectroscopy grade.

Lauryl Dimethyl Amine Oxide (*N,N*-Dimethyldodecylamine-*N*-oxide), $C_{14}H_{31}NO$ [1643-20-5]—**229.41**—Use a suitable grade.

[NOTE—A suitable grade is available from Fluka, catalog number 40234, www.sigma-aldrich.com.]

Lead Acetate, $Pb(C_2H_3O_2)_2 \cdot 3H_2O$ —**379.33** [6080-56-4]—Use ACS reagent grade.

Lead Acetate Paper—Immerse filter paper weighing about 80 g per square meter in a mixture of diluted acetic

acid and lead acetate TS (1:10). Remove, dry, and cut into 15-mm \times 40-mm strips.

Lead Monoxide (*Litharge*), PbO —**223.20**

[1317-36-8]—Heavy, yellowish or reddish-yellow powder. Insoluble in water and in alcohol; soluble in acetic acid, in diluted nitric acid, and in warm solutions of the fixed alkali hydroxides.

Assay—Accurately weigh about 300 mg, freshly ignited in a muffle furnace at $600 \pm 50^\circ$, and dissolve it by warming with 10 mL of water and 1 mL of glacial acetic acid. Dilute with 75 mL of water, heat to boiling, add 50.0 mL of 0.1 N potassium dichromate VS, and boil for 2 to 3 minutes. Cool, transfer to a 200-mL volumetric flask with the aid of water, dilute with water to volume, mix, and allow to settle. Withdraw 100.0 mL of the clear liquid, and transfer to a glass-stoppered flask. Add 10 mL of diluted sulfuric acid and 1 g of potassium iodide, insert the stopper, mix gently, and allow to stand for 10 minutes. Then titrate the liberated iodine, representing the excess of dichromate, with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached: each mL of 0.1 N potassium dichromate is equivalent to 7.440 mg of PbO . Not less than 98% is found.

Insoluble in acetic acid—Dissolve 2 g in 30 mL of dilute glacial acetic acid (1 in 2), boil gently for 5 minutes, filter, wash the residue with diluted acetic acid, and dry at 105° for 2 hours: the residue weighs not more than 10 mg (0.5%).

Substances not precipitated by hydrogen sulfide—Completely precipitate the lead from the filtrate obtained in the test for *Insoluble in acetic acid* by passing hydrogen sulfide into it, filter, and wash the precipitate with 20 mL of water. To one-half of the mixed filtrate and washings add 5 drops of sulfuric acid, evaporate to dryness, and ignite at $800 \pm 25^\circ$ for 15 minutes: the residue weighs not more than 5 mg (0.5%).

Volatile substances—Accurately weigh about 5 g, and heat strongly in a covered porcelain crucible: it loses not more than 2.0% of its weight.

Lead Nitrate, $Pb(NO_3)_2$ —**331.21** [10099-74-8]—Use ACS reagent grade.

Lead Perchlorate, $Pb(ClO_4)_2 \cdot 3H_2O$ —**460.15**—Use ACS reagent grade.

Lead Tetraacetate, $C_8H_{12}O_8Pb$ —**443.38** [546-67-8]—Colorless to pinkish crystals. Soluble in hot glacial acetic acid, in chloroform, in nitrobenzene, and in tetrachloroethane. Hydrolyzed by water, producing brown lead dioxide and acetic acid. Unstable in air.

Melting range (741): between 175° and 180°.

Linalool (3,7-Dimethyl-1,6-octadien-3-ol), $C_{10}H_{18}O$ —**154.25** [78-70-6]—Use a suitable grade.

Linoleic Acid, $C_{18}H_{32}O_2$ —**280.4** [60-33-3]—Clear, colorless liquid. Use a suitable grade.

α -Lipoic Acid, $C_8H_{14}O_2S_2$ —**206.3** [1077-28-7]—Yellow powder. Use a suitable grade.

Liquid Petrolatum—Use *Mineral Oil*.

Lithium Chloride, $LiCl$ —**42.39** [7447-41-8]—Use ACS reagent grade.

Lithium Hydroxide, $LiOH \cdot H_2O$ —**41.96** [1310-65-2]—Use ACS reagent grade.

Lithium Metaborate, $LiBO_2$ —**49.75** [13453-69-5]—Use ACS reagent grade.

Lithium Nitrate, $LiNO_3$ —**68.95** [7790-69-4]—Colorless crystals. Use a suitable grade labeled to contain not less than 97.0%.

Lithium Perchlorate, $LiClO_4$ —**106.39** [7791-03-9]—Use ACS reagent grade.

Lithium Sulfate, $Li_2SO_4 \cdot H_2O$ —**127.96** [10377-48-7]—Use ACS reagent grade.

Lithocholic Acid, $C_{24}H_{40}O_3$ —**376.57** [434-13-9]—White powder.

Assay—When tested by thin-layer chromatography, with the use of plates coated with chromatographic silica gel

mixture, a developing system consisting of a mixture of toluene, 1,4-dioxane, and acetic acid (15.2:4.2:0.6), and sprayed with a mixture of sulfuric acid and methanol (1:1), heated at 110° for 20 minutes, and examined visually and under long-wavelength UV light, a single spot is exhibited.

Melting range (741): between 184° and 186°.

Litmus [1393-92-6]—A blue pigment prepared from various species of *Rocella* DeCandolle, *Lecanora* Acharius, or other lichens (Fam. Parmeliaceae).

Description—Cubes, masses, fragments, or granules, of an indigo blue or deep violet color. Has the combined odor of indigo and violets, and tinges the saliva a deep blue. The indicator substances it contains are soluble in water and less soluble or insoluble in alcohol.

Ash—It yields not more than 60.0% of ash.

Locust Bean Gum—A gum obtained from the ground endosperms of *Ceratonia siliqua* Linné Taub. (Fam. Leguminosae). Use Locust Bean Gum, FCC.

L-Lysine (2,6-Diaminohexanoic Acid), $C_6H_{14}N_2O_2$ —**146.19** [56-87-1]—Crystalline needles or hexagonal plates. Soluble in water; very slightly soluble in alcohol; insoluble in ether.

Specific rotation (781): between +25.5° and +26.0°.

Test solution: 20 mg per mL, in dilute hydrochloric acid (1 in 2).

Nitrogen content, Method I (461): between 18.88% and 19.44% of N is found, corresponding to not less than 98.5% of $C_6H_{14}N_2O_2$, the test specimen previously having been dried at 105° for 2 hours.

Magnesium, Mg—**24.305** [7439-95-4]—Silvery metal in ribbon form. Reacts slowly with water at room temperature. Dissolves readily in dilute acids with the liberation of hydrogen.

Assay—Transfer 1 g, accurately weighed, to a 250-mL volumetric flask, and dissolve in a mixture of 15 mL of hydrochloric acid and 85 mL of water. When solution is complete, dilute with water to volume, and mix. Pipet 25 mL of the dilution into a 400-mL beaker, dilute with water to 250 mL, add 20 mL of ammonia-ammonium chloride TS and a few mg of eriochrome black T trituration, and titrate with 0.1 M edetate disodium VS to a blue endpoint. Each mL of 0.1 M edetate disodium VS is equivalent to 2.430 mg of Mg. Not less than 99% is found.

Magnesium Acetate, $Mg(C_2H_3O_2)_2 \cdot 4H_2O$ —**214.45** [142-72-3]—Use ACS reagent grade.

Magnesium Chloride, $MgCl_2 \cdot 6H_2O$ —**203.30** [7786-30-3]—Use ACS reagent grade.

Magnesium Nitrate, $Mg(NO_3)_2 \cdot 6H_2O$ —**256.41** [10377-60-3]—Use ACS reagent grade.

Magnesium Oxide, MgO —**40.30** [1309-48-4]—Use ACS reagent grade.

Magnesium Oxide, Chromatographic—Use a suitable grade.

Magnesium Perchlorate, Anhydrous, $Mg(ClO_4)_2$ —**223.21** [10034-81-8]—Use ACS reagent grade.

Magnesium Silicate, Activated—Use a suitable grade.

Magnesium Silicate, Chromatographic—Extremely white, hard, powdered (60- to 100-mesh) magnesia-silica gel. Suitable for use as an adsorbant in column chromatography.

Magnesium Sulfate, $MgSO_4 \cdot 7H_2O$ —**246.48** [10034-99-8]—Use ACS reagent grade.

Magnesium Sulfate, Anhydrous, $MgSO_4$ —**120.37**

[7487-88-9]—Anhydrous Magnesium Sulfate may be prepared as follows. Place a suitable quantity of magnesium sulfate (see above), preferably powdered, in a shallow vessel, and expose to a temperature of about 80° for several hours with occasional stirring. Then heat at 275° to 300° until the weight is practically constant. Transfer the product

while still warm to tight containers, as the anhydrous salt is very hygroscopic.

Malachite Green G—See *Brilliant Green*.

Maleic Acid, $C_4H_4O_4$ —**116.07** [110-16-7]—White, crystalline powder. Soluble in 1.5 parts of water, in 2 parts of alcohol, and in 12 parts of ether.

Assay—Dissolve about 2 g, accurately weighed, in 100 mL of water and titrate with 1 N sodium hydroxide VS, using phenolphthalein TS as the indicator. Each mL of 1 N sodium hydroxide is equivalent to 58.04 mg of $C_4H_4O_4$; not less than 99% of $C_4H_4O_4$, calculated on the dried basis, is found.

Loss on drying—Dry it in vacuum over phosphorus pentoxide for 2 hours: it loses not more than 1.5% of its weight.

Residue on ignition (281): not more than 0.1%.

Maltotriose, $C_{18}H_{32}O_{16}$ —**504.44** [1109-28-0]—Use a suitable grade with a content of not less than 95%.

Manganese Dioxide—See *Manganese Dioxide, Activated*. **Manganese Dioxide, Activated** (*Manganese (IV) Oxide, Activated*), MnO_2 —**86.94** [1313-13-9]—Use a suitable grade.

Melamine (2,4,6-Triamino-1,3,5-triazine), $C_3H_6N_6$ —**126.1** [108-78-1]—Use a suitable grade.

2-Mercaptoethanol (β -Mercaptoethanol), C_2H_5OS —**78.13** [60-24-2]—Use a suitable grade.

Mercuric Acetate, $Hg(C_2H_3O_2)_2$ —**318.68**

[1600-27-7]—Use ACS reagent grade.

Mercuric Bromide, $HgBr_2$ —**360.40** [7789-47-1]—Use ACS reagent grade.

Mercuric Chloride, $HgCl_2$ —**271.50** [7487-94-7]—Use ACS reagent grade.

Mercuric Iodide, Red, HgI_2 —**454.40** [7774-29-0]—Use ACS reagent grade.

Mercuric Nitrate, $Hg(NO_3)_2 \cdot xH_2O$ —**342.62**

[10045-94-0]—Use ACS reagent grade. This reagent is available as either the mono- or dihydrate.

Mercuric Oxide, Yellow, HgO —**216.59**

[21908-53-2]—Use ACS reagent grade.

Mercuric Sulfate, $HgSO_4$ —**296.65** [7783-35-9]—Use ACS reagent grade.

Mercuric Thiocyanate, $Hg(SCN)_2$ —**316.76**

[592-85-8]—White, crystalline powder. Very slightly soluble in water; soluble in solutions of sodium chloride; slightly soluble in alcohol and in ether.

Mercurous Nitrate Dihydrate (*Mercury (I) Nitrate Dihydrate*), $Hg_2(NO_3)_2 \cdot 2H_2O$ —**561.22**—Use ACS reagent grade.

Mercury, Hg —**At. Wt. 200.59** [7439-97-6]—Use ACS reagent grade.

Mesityl Oxide, $C_6H_{10}O$ —**98.14** [141-79-7]—Colorless liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 150°; the detector temperature is maintained at 300°; the column temperature is maintained at 50° and programmed to rise 10° per minute to 200°. The area of the $C_6H_{10}O$ peak is not less than 98% of the total peak area.

Refractive index (831): between 1.443 and 1.447 at 20°.

Metanil Yellow (*Acid Yellow 36*;

3-(4-Anilinophenylazo)benzenesulfonic Acid Sodium Salt), $C_{18}H_{14}N_3NaO_3S$ —**375.38** [587-98-4]—Use a suitable grade with a dye content of NLT 70%.

Metaphenylenediamine Hydrochloride (*Metaphenylenediamine Dihydrochloride*), $C_6H_4(NH_2)_2 \cdot 2HCl$ —**181.06**—White or slightly reddish-white, crystalline powder. Easily soluble in water. On exposure to light it acquires a reddish color. Store it protected from light.

Solubility—A solution of 1 g in 200 mL of water is colorless.

Residue on ignition (Reagent test)—Ignite 1 g with 0.5 mL of sulfuric acid: the residue weighs not more than 1 mg (0.1%).

[NOTE—Metaphenylenediamine hydrochloride solution can be decolorized by treatment with a small quantity of activated charcoal.]

Metaphosphoric Acid (*Vitreous Sodium Acid Metaphosphate*), HPO_3 —**79.98** [37267-86-0]—Use ACS reagent grade.

Methacrylic Acid [79-41-4]—Use a suitable grade.

Methanesulfonic Acid, $\text{CH}_3\text{O}_3\text{S}$ —**96.11** [75-75-2]—Use a suitable grade.

Methanol (*Methyl Alcohol*), CH_3OH —**32.04** [67-56-1]—Use ACS reagent grade.

Methanol, Aldehyde-Free, CH_3OH —**32.04**—Dissolve 25 g of iodine in 1 L of methanol and pour the solution, with constant stirring, into 400 mL of 1 N sodium hydroxide. Add 150 mL of water, and allow to stand for 16 hours. Filter, and boil under a reflux condenser until the odor of iodoform disappears. Distill the solution by fractional distillation. It contains not more than 0.001% of aldehydes and ketones.

Methanol, Anhydrous—Use *Methanol*.

Methanol, Spectrophotometric—Use ACS reagent grade Methanol Suitable for Use in UV Spectrophotometry.

Methenamine (*Hexamethylenetetramine*; *Urotropine*; *Uritone*; *Hexamine*), $\text{C}_6\text{H}_{12}\text{N}_4$ —**140.19** [100-97-0]—Use ACS reagent grade Hexamethylenetetramine.

7-Methoxycoumarin (*Herniarin*; *Methyl Umbelliferol Ether*), $\text{C}_{10}\text{H}_8\text{O}_3$ —**176.17** [531-59-9]—Use a suitable grade with a content of not less than 98%.

Methoxyethanol (*Ethylene Glycol Monomethyl Ether*; *2-Methoxyethanol*), $\text{CH}_3\text{OCH}_2\text{CH}_2\text{OH}$ —**76.09** [109-86-4]—Use ACS reagent grade.

2-Methoxyethanol (*Ethylene Glycol Monomethyl Ether*; *Methoxyethanol*), $\text{CH}_3\text{OCH}_2\text{CH}_2\text{OH}$ —**76.09** [109-86-4]—See *Methoxyethanol*.

Add the following:

▲ **5-Methoxy-1H-benzimidazole-2-thiol** (*5-Methoxy-2-benzimidazolethiol*), $\text{C}_8\text{H}_8\text{N}_2\text{OS}$ —**180.23** [37052-78-1]—Use a suitable grade with a content of NLT 99.0%.▲ *USP36*

5-Methoxy-2-methyl-3-indoleacetic Acid, $\text{C}_{12}\text{H}_{13}\text{NO}_3$ —**219.24** [2882-15-7]—Off-white powder.

Assay—Transfer about 110 mg, accurately weighed, to a 100-mL beaker. Add 30 mL of methanol and dissolve by stirring. Add 40 mL of water, and mix. Titrate with 0.1 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination and make any necessary correction. Each mL of 0.1 N sodium hydroxide is equivalent to 21.92 mg of $\text{C}_{12}\text{H}_{13}\text{NO}_3$. Not less than 98% is found.

Melting range (741): between 161° and 168°, but the range between beginning and end of melting does not exceed 3°.

Methoxyphenylacetic Acid (*α-Methoxyphenylacetic Acid*), $\text{C}_9\text{H}_{10}\text{O}_3$ —**166.2** [7021-09-2]—Use a suitable grade.

Methyl Acetate, $\text{C}_3\text{H}_6\text{O}_2$ —**74.08** [74-20-9]—Colorless liquid. Soluble in water. Miscible with alcohol and with ether.

Specific gravity (841): about 0.933.

Refractive index (831): between 1.3615 and 1.3625 at 20°.

Boiling range (Reagent test)—Not less than 95% distills between 57° and 58°.

Methyl 4-Aminobenzoate, $\text{C}_8\text{H}_9\text{NO}_2$ —**151.16** [619-45-4]—Off-white powder.

Assay—Dissolve about 38 mg, accurately weighed, in 50 mL of glacial acetic acid. Titrate with 0.1 N perchloric acid VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction.

Each mL of 0.1 N perchloric acid is equivalent to 15.12 mg of $\text{C}_8\text{H}_9\text{NO}_2$. Not less than 99.0% is found.

Melting range (741): between 108° and 110°.

Methyl Arachidate (*Eicosanoic acid, methyl ester*), $\text{C}_{21}\text{H}_{42}\text{O}_2$ —**326.56** [1120-28-1]—Off-white flakes.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a thermal-conductivity detector, helium being used as the carrier gas. The following conditions have been found suitable: a 2.0-mm × 1.8-m glass column packed with 5% G2 phase on support S1A; the injection port temperature is maintained at 300°; the detector temperature is maintained at 230° and programmed to rise 3° per minute to 280°. The area of the $\text{C}_{21}\text{H}_{42}\text{O}_2$ peak is not less than 99% of the total peak area.

Melting range (741): between 46° and 51°.

Methyl Behenate, $\text{C}_{23}\text{H}_{46}\text{O}_2$ —**354.61** [929-77-1]—White powder.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a thermal conductivity detector, helium being used as the carrier gas. The following conditions have been found suitable: a 2.0-mm × 1.8-m glass column packed with 5% G3 phase on support S1A; the injection port temperature is maintained at 300°; the detector temperature is maintained at 300°; the initial temperature of the oven is 220°, which is held for 2 minutes, and then programmed to rise 3° per minute to attain a final temperature of 270°, which is held for 10 minutes. The area of the $\text{C}_{23}\text{H}_{46}\text{O}_2$ peak is not less than 98% of the total peak area.

Melting range (741): between 54° and 56°.

Methyl Benzenesulfonate, $\text{C}_7\text{H}_8\text{O}_3\text{S}$ —**172.20** [80-18-2]—Use a suitable grade.

Methyl Caprate, $\text{C}_{11}\text{H}_{22}\text{O}_2$ —**186.29** [110-42-9]—Colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm × 30-m capillary column coated with a 1-μm layer of phase G2; the injection port temperature is maintained at 250°; the detector temperature is maintained at 300°; the column temperature is maintained at 150° and programmed to rise 10° per minute to 280°. The area of the $\text{C}_{11}\text{H}_{22}\text{O}_2$ peak is not less than 98.5% of the total peak area.

Methyl Caprylate, $\text{C}_9\text{H}_{18}\text{O}_2$ —**158.24** [111-11-5]—Colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm × 30-m capillary column coated with a 1-μm layer of phase G2; the injection port temperature is maintained at 230°; the detector temperature is maintained at 300°; the column temperature is maintained at 130° and programmed to rise 10° per minute to 280°. The area of the $\text{C}_9\text{H}_{18}\text{O}_2$ peak is not less than 98.5% of the total peak area.

Methyl Carbamate, $\text{C}_2\text{H}_5\text{NO}_2$ —**75.07** [598-55-0]—White crystals. Freely soluble in water.

Melting range (741): between 54° and 56°.

Methyl Chloroform (*Methylchloroform*; *1,1,1-Trichloroethane*), CH_3CCl_3 —**133.40** [71-55-6]—Use ACS reagent grade.

Methyl Erucate, $\text{C}_{23}\text{H}_{44}\text{O}_2$ —**352.59** [1120-34-9]—Colorless liquid.

Methyl Ethyl Ketone, $\text{CH}_3\text{COC}_2\text{H}_5$ —**72.11** [78-93-3]—Use ACS reagent grade 2-butanone.

Methyl Green (*Methyl Green Zinc Chloride Double Salt*; *Ethyl Green Zinc Chloride Double Salt*; *C.I. 42590*), $\text{C}_{27}\text{H}_{35}\text{Cl}_2\text{N}_3 \cdot \text{ZnCl}_2$ —**608.78** [7114-03-6]—Use a suitable grade for microscopy.

Methyl Heptadecanoate, $\text{C}_{18}\text{H}_{36}\text{O}_2$ —**284.48** [1731-92-6]—White, crystalline flakes.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G8; the injection port temperature is maintained at 220°; the detector temperature is maintained at 220°; the column temperature is maintained at 180° and programmed to rise 4° per minute to 220°. The area of the $C_{18}H_{36}O_2$ peak is not less than 99% of the total peak area.

Melting range (741): between 31° and 32°.

Methyl Iodide, (Iodomethane), CH_3I —**141.94**

[74-88-4]—Colorless, heavy, transparent liquid. Slightly soluble in water. Miscible with alcohol, with ether, and with solvent hexane. Turns brown on exposure to light as a result of liberation of iodine.

Use a suitable grade with a content of not less than 99%.

Methyl Isobutyl Ketone—See 4-Methyl-2-pentanone.

Methyl Laurate, $C_{13}H_{26}O_2$ —**214.34** [110-82-0]—Colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 280°; the detector temperature is maintained at 300°; the column temperature is maintained at 180° and programmed to rise 10° per minute to 280°. The area of the $C_{13}H_{26}O_2$ peak is not less than 99.45% of the total peak area.

Methyl Lignocerate, $C_{25}H_{50}O_2$ —**382.66** [2442-49-1]—White crystals.

Methyl Linoleate, $C_{19}H_{34}O_2$ —**294.47** [112-63-0]—Colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 300°; the detector temperature is maintained at 300°; the column temperature is maintained at 200° and programmed to rise 10° per minute to 300°. The area of the $C_{19}H_{34}O_2$ peak is not less than 99% of the total peak area.

Methyl Linolenate, $C_{19}H_{32}O_2$ —**292.46** [301-00-8]—Colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase 14% cyanopropylphenyl-86% dimethylpolysiloxane; the injection port temperature is maintained at 280°; the detector temperature is maintained at 300°; the column temperature is maintained at 180° and programmed to rise 10° per minute to 280°. The area of the $C_{19}H_{32}O_2$ peak is not less than 99% of the total peak area.

Refractive index (831): between 1.469 and 1.473 at 20°.

Methyl Methacrylate [80-62-6]—Use a suitable grade.

Methyl Myristate, $C_{15}H_{30}O_2$ —**242.40** [124-10-7]—Colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas.

The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 300°; the detector temperature is maintained at 300°; the column temperature is maintained at 200° and programmed to rise 10° per minute to 300°. The area of the $C_{15}H_{30}O_2$ peak is not less than 99% of the total peak area.

Refractive index (831): between 1.434 and 1.438 at 20°.

Methyl Oleate, $C_{19}H_{36}O_2$ —**296.49** [112-62-9]—Colorless liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 300°; the detector temperature is maintained at 300°; the column temperature is maintained at 230° and programmed to rise 10° per minute to 280°. The area of the $C_{19}H_{36}O_2$ peak is not less than 99% of the total peak area.

Refractive index (831): 1.452 at 20°.

Methyl Palmitate, $C_{17}H_{34}O_2$ —**270.45** [112-39-0]—White solid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 300°; the detector temperature is maintained at 300°; the column temperature is maintained at 200° and programmed to rise 10° per minute to 300°. The area of the $C_{17}H_{34}O_2$ peak is not less than 96.5% of the total peak area.

Methyl Red (2-[4-Dimethylaminophenylazo]benzoic Acid; C. I. Acid Red 2) $C_{15}H_{15}N_3O_2$, free acid—**269.30**

[493-52-7] $C_{15}H_{14}N_3O_2Na$, sodium salt—**291.28**

[845-10-3]—Use ACS reagent grade. The free acid is recommended for nonaqueous titrations, particularly when an aprotic solvent is used. The sodium salt is recommended for titrations in aqueous media and also for nonaqueous titrations where the medium is an amphiprotic solvent. The hydrochloride salt is recommended for titrations in aqueous media and amphiprotic solvents.

Methyl Stearate, $C_{19}H_{38}O_2$ —**298.50** [112-61-8]—Off-white, crystalline solid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 300°; the detector temperature is maintained at 300°; the column temperature is maintained at 200° and programmed to rise 10° per minute to 300°. The area of the $C_{19}H_{38}O_2$ peak is not less than 99% of the total peak area.

Melting range (741): between 40° and 42°.

Methyl Sulfoxide [67-68-5]—See Dimethyl Sulfoxide.

Methyl Yellow (p-Dimethylaminoazobenzene), $C_{14}H_{15}N_3$ —**225.3** [60-11-7]—Use a suitable grade.

Methylamine, 40 Percent in Water, CH_3N —**31.06** [74-89-5]—Colorless liquid.

Assay—Using a syringe, transfer about 0.5 mL of a well-shaken specimen to 100 mL of water at a point below the surface of the water. Determine the weight of the specimen by weighing the syringe before and after the transfer. Mix, and titrate with 0.5 N hydrochloric acid VS, determining the endpoint potentiometrically, using a silver-silver chloride pH electrode and a calomel reference electrode. Perform a blank determination, and make any necessary correction. Each mL of 0.5 N hydrochloric acid is equivalent to 15.53 mg of CH_3N : between 39.0% and 41.0% is found.

Refractive index (831): between 1.3680 and 1.3710, at 20°.

p-Methylaminophenol Sulfate, $(p\text{-CH}_3\text{NHC}_6\text{H}_4\text{OH})_2 \cdot \text{H}_2\text{SO}_4$ —**344.38** [55-55-0]—Use ACS reagent grade.

4-Methylbenzophenone, $\text{C}_{14}\text{H}_{12}\text{O}$ —**196.25** [134-84-9]—Use a suitable grade.

Melting range (741): between 56.5° and 57°.

Methylbenzothiazolone Hydrazone Hydrochloride, $\text{C}_8\text{H}_{10}\text{ClN}_3\text{S} \cdot \text{H}_2\text{O}$ —**233.7** [38894-11-0] (monohydrate form)—**215.70** (anhydrous form); [149022-15-1] (hydrate form)—An almost white or yellowish, crystalline powder.

Suitability for determination of aldehydes—To 2 mL of aldehyde-free methanol add 60 μL of a 1 g per L solution of propionaldehyde in aldehyde-free methanol and 5 mL of a 4 g per L solution of methylbenzothiazolone hydrazone hydrochloride. Mix, and allow to stand for 30 minutes. Prepare a blank, omitting the propionaldehyde solution. Add 25.0 mL of a 2 g per L solution of ferric chloride to the test solution and to the blank, dilute with acetone to 100.0 mL, and mix. The absorbance of the test solution, measured at 660 nm using the blank as compensation liquid, is not less than 0.62.

Use a suitable grade with a content of not less than 97%.

(R)-(+)-alpha-Methylbenzyl Isocyanate ((R)-(+)-1-Phenylethyl Isocyanate), $\text{C}_9\text{H}_9\text{NO}$ —**147.17** [33375-06-3]—Use a suitable grade with a content of NLT 99.0%.

(S)-(-)-alpha-Methylbenzyl Isocyanate $\text{C}_9\text{H}_9\text{NO}$ —**147.18** [14649-03-7]—Use a suitable grade.

Methylene Blue, $\text{C}_{16}\text{H}_{18}\text{ClN}_3\text{S} \cdot 3\text{H}_2\text{O}$ —**373.90** [7220-79-3]—Dark green crystals or a crystalline powder, having a bronzelike luster. One g dissolves in about 25 mL of water and in about 65 mL of alcohol. Soluble in chloroform. Use a suitable grade with a dye content of not less than 85%.

Methylene Chloride (Dichloromethane), CH_2Cl_2 —**84.93** [75-09-2]—Use ACS reagent grade Dichloromethane.

5,5'-Methylenedisalicylic Acid (3,3'-Methylene-bis[6-hydroxybenzoic Acid]), $\text{C}_{15}\text{H}_{12}\text{O}_6$ —**288.25** [122-25-8]—Use a suitable grade.

3-O-Methylestrone, $\text{C}_{19}\text{H}_{24}\text{O}_2$ —**284.39**—Use a suitable grade.

[NOTE—Commercially available as catalog number 1883-5 from Research Plus, Inc., P.O. Box 324, Bayonne, NJ 07002, fax number 908-754-2901, Web site: www.researchplus.com.]

2-Methyl-5-nitroimidazole, $\text{C}_4\text{H}_4\text{N}_3\text{O}_2$ —**127.10** [88052-22-2]—Use a suitable grade.

[NOTE—Available as Catalog No. 13,625-5 from Sigma-Aldrich, www.sigma-aldrich.com.]

N-Methyl-N-nitroso-p-toluenesulfonamide (p-Tolylsulfonfylmethylnitrosamide), $\text{C}_8\text{H}_{10}\text{N}_2\text{O}_3\text{S}$ —**214.24**—Light yellow crystals or powder. Insoluble in water; soluble in benzene, in carbon tetrachloride, and in chloroform.

Melting range (741): between 59° and 63°, but the range between beginning and end of melting does not exceed 2°.

4-Methylpentan-2-ol, $\text{C}_6\text{H}_{14}\text{O}$ —**102.2**—Use a suitable grade.

2-Methylpentane (2-Methyl-pentane; 1,1-Dimethylbutane; Isohexane), C_6H_{14} —**86.18** [107-83-5]—Use a suitable grade with a content of not less than 99.0%.

4-Methyl-2-pentanone (Methyl Isobutyl Ketone), $(\text{CH}_3)_2\text{CHCH}_2\text{COCH}_3$ —**100.16** [108-10-1]—Use ACS reagent grade.

2-Methyl-2-propyl-1,3-propanediol, $\text{C}_7\text{H}_{16}\text{O}_2$ —**132.20** [78-26-2]—White crystals, melting at about 58°.

N-Methylpyrrolidine (1-Methylpyrrolidine), $\text{C}_4\text{H}_8\text{NCH}_3$ —**85.15** [120-94-5]—Use a suitable grade.

Mineral Acid—Use Hydrochloric Acid or Sulfuric Acid.

5,800, 23,700, and 100,000 Molecular Weight (MW)

Pullulan Standards (a commercial Pullulan Standard set contains standards having several molecular weights: 5,800; 12,000; 24,000; 48,000; 100,000; 186,000; 380,000; and 750,000) [9057-02-7]—Use a suitable grade. Each individual Pullulan Standard with a different molecular weight, such as 5,800, 24,000, or 100,000, is equivalently used.

[NOTE—The standard set is available from Polymer Laboratories (www.polymerlabs.com), Sigma-Aldrich (www.sigma-aldrich.com), and Waters (www.waters.com).]

Molybdic Acid (85 Percent Molybdic Acid) [7782-91-4]—Use ACS reagent grade.

Monobasic Potassium Phosphate—See Potassium Phosphate, Monobasic.

Monobasic Sodium Phosphate—See Sodium Phosphate, Monobasic.

Monochloroacetic Acid (Chloroacetic Acid, Chloroethanoic Acid), CH_2ClCOOH —**94.50** [79-11-8]—Use ACS reagent grade.

Monoethanolamine, (2-Aminoethanol) $\text{C}_2\text{H}_7\text{NO}$ —**61.08**—Use ACS reagent grade.

Morin (Morin Hydrate; 2',3,4',5,7-Pentahydroxyflavone Monohydrate), $\text{C}_{15}\text{H}_{10}\text{O}_7 \cdot \text{H}_2\text{O}$ —**320.25** [480-16-0]—Use a suitable grade.

Morpholine (Tetrahydro-1,4-oxazine), $\text{C}_4\text{H}_9\text{NO}$ —**87.12** [110-91-8]—Use ACS reagent grade.

Naphthalene, C_{10}H_8 —**128.17** [91-20-3]—Monoclinic prismatic plates, or white scales or powder. Use a suitable grade with a content of not less than 98%.

1,3-Naphthalenediol (Naphthoresorcinol), $\text{C}_{10}\text{H}_6(\text{OH})_2$ —**160.17** [132-86-5]—Grayish-white to tan crystals or powder. Freely soluble in methanol; sparingly soluble in water, in alcohol, and in ether.

Melting range (741): between 122° and 127°.

Solubility in methanol—Dissolve 500 mg in 50 mL of methanol: the solution is clear and complete.

2,7-Naphthalenediol (2,7-Dihydroxynaphthalene), $\text{C}_{10}\text{H}_8\text{O}_2$ —**160.17** [582-17-2]—Off-white to yellow, crystalline solid or powder. Dissolves in acetone.

Melting range (741): between 187° and 191°.

2-Naphthalenesulfonic Acid, $\text{C}_{10}\text{H}_8\text{O}_3\text{S} \cdot \text{H}_2\text{O}$ —**226.25** [120-18-3]—Off-white to light gray crystals. Soluble in water.

Assay—Dissolve about 1 g, accurately weighed, in 100 mL of water, add phenolphthalein TS, and titrate with 0.1 N sodium hydroxide VS. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N sodium hydroxide is equivalent to 22.63 mg of $\text{C}_{10}\text{H}_8\text{O}_3\text{S} \cdot \text{H}_2\text{O}$. Not less than 98.0% is found.

Melting range (741): between 122° and 126°, but the range between beginning and end of melting does not exceed 2°.

1-Naphthol (*Alphanaphthol*), $C_{10}H_7OH$ —**144.17** [90-15-3]—Colorless or slightly pinkish crystals or crystalline powder.

2-Naphthol (*Betanaphthol*), $C_{10}H_7OH$ —**144.17** [135-19-3]—White leaflets or crystalline powder. Discolors on exposure to light. Very slightly soluble in water; soluble in alcohol, in ether, in chloroform, and in solutions of alkali hydroxides.

Melting range (741): between 121° and 123°.

Solubility in alcohol—A solution of 1 g in 10 mL of alcohol is complete and colorless or practically so.

Residue on ignition (Reagent test): not more than 0.05%.

Acidity—Shake 1 g with 50 mL of water occasionally during 15 minutes, and filter: the filtrate is neutral to litmus.

1-Naphthol—Boil 100 mg with 10 mL of water until dissolved, cool, and filter. Add to the filtrate 0.3 mL of 1 N sodium hydroxide and 0.3 mL of 0.1 N iodine: no violet color is produced.

Insoluble in ammonia (naphthalene, etc.)—Shake 500 mg with 30 mL of ammonia TS: the 2-naphthol dissolves completely and the solution is not darker than pale yellow.

Naphthol Dipotassium Disulfonate (*2-Naphthol-6,8-dipotassium Disulfonate*), $C_{10}H_6K_2O_7S_2$ —**380.48** [842-18-2]—Use a suitable grade.

[NOTE—A suitable grade is available as “2-naphthyl-6,8-disulfonic acid dipotassium salt” from Pfaltz and Bauer, Inc., www.pfaltzandbauer.com.]

Naphthol Disodium Disulfonate (*2-Naphthol-3,6-disodium Disulfonate*), $C_{10}H_6Na_2O_7S_2$ —**348.26**—Use a suitable grade.

p-Naphtholbenzein, $C_{27}H_{18}O_2$ —**374.43** [145-50-6]—Red-brown powder. Use a suitable grade.

β-Naphthoquinone-4-sodium Sulfonate, $C_{10}H_5NaO_5S$ —**260.20**—Yellow to orange-yellow crystals or crystalline powder. Soluble in about 10 parts of water; insoluble in alcohol.

Loss on drying (731)—Dry it in vacuum at about 50°: it loses not more than 2.0% of its weight.

Residue on ignition (Reagent test)—Ignite 1 g of dried sample with 3 mL of sulfuric acid: the residue weighs between 265 and 280 mg (between 26.5% and 28.0%).

Naphthoresorcinol (*1,3-Dihydroresorcinol*), $C_{10}H_8O_2$ —**160.17** [132-86-5]—Use a suitable grade.

2-Naphthyl Chloroformate (*Chloroformic Acid 2-Naphthyl Ester*), $ClCOOC_{10}H_7$ —**206.62** [7693-50-7]—Use a suitable grade.

[NOTE—A suitable grade is available from TCI America, www.tciamerica.com.]

1-Naphthylamine, $C_{10}H_9N$ —**143.19** [134-32-7]—Use a suitable grade.

1-Naphthylamine Hydrochloride, $C_{10}H_7NH_2 \cdot HCl$ —**179.65** [552-46-5]—White, crystalline powder that turns bluish upon exposure to light and air. Soluble in water, in alcohol, and in ether.

A 1 in 100 solution, make slightly acid with acetic acid, gives a violet color with 5 drops of ferric chloride TS. A 1 in 40 solution in diluted acetic acid is colorless and not more than slightly opalescent.

Residue on ignition (Reagent test)—Ignite 200 mg with a few drops of sulfuric acid: the weight of the residue is negligible.

N-(1-Naphthyl)ethylenediamine Dihydrochloride, $C_{10}H_7NH(CH_2)_2NH_2 \cdot 2HCl$ —**259.17** [1465-25-4]—Use ACS reagent grade.

Neutralized Alcohol—See *Alcohol, Neutralized*.

Nickel, Ni—**58.6934** [7440-02-0]—Use a suitable grade.

Nickel-Aluminum Catalyst—Use a suitable grade.

[NOTE—A suitable grade is “Raney Nickel, Active Catalyst,” available as “aluminum-nickel alloy,” catalog number

72240, available from Fluka Chemical Corp., fax 1-800-962-9591, Web site: www.sigma-aldrich.com.]

Nickel Sulfate, $NiSO_4 \cdot 6H_2O$ —**262.85** [7786-81-4]—Use ACS reagent grade.

Nickel (II) Sulfate Heptahydrate, $NiSO_4 \cdot 7H_2O$ —**280.9** [10101-98-1]—Use a suitable grade.

β-Nicotinamide Adenine Dinucleotide, $C_{21}H_{27}N_7O_{14}P_2$ —**663.4** [53-84-9]—White, very hygroscopic powder. Freely soluble in water.

Assay—Dissolve 17.9 g of anhydrous dibasic sodium phosphate in water to make 500 mL (*Solution A*). Dissolve 6.8 g of monobasic potassium phosphate in water to make 500 mL (*Solution B*). To a volume of *Solution A*, add *Solution B* until the mixture is adjusted to a pH of 7.0 (about 2:1 by volume of *Solutions A* and *B*) to obtain a pH 7.0 Buffer. Transfer about 25 mg of β-nicotinamide adenine dinucleotide, accurately weighed, to a 25-mL volumetric flask, dissolve in and dilute with water to volume, and mix. Transfer 0.2 mL of this solution to a 10-mL volumetric flask, dilute with pH 7.0 Buffer to volume, and mix. Use this solution as the *Assay preparation*. Determine the absorbances of the *Assay preparation* and the pH 7.0 Buffer in 1-cm cells at a wavelength of 260 nm, using water as the reference. Calculate the quantity, in mg, of $C_{21}H_{27}N_7O_{14}P_2$ in the portion of β-nicotinamide adenine dinucleotide taken by the formula:

$$(0.6634/17.6)(10/0.2)(25)(A_A - A_B)$$

in which A_A and A_B are the absorbances of the *Assay preparation* and the pH 7.0 Buffer, respectively. Not less than 94.5% is found.

Nicotinamide Adenine Dinucleotide Phosphate-adenosine-5'-triphosphate Mixture—Use a suitable grade.

Suitability—When used in the assay of lactulose, determine that a suitable absorbance-versus-concentration slope is obtained, using USP Lactulose RS, the reagent blank absorbance being not more than 0.020. The commercially available reagent contains 64 mg of nicotinamide adenine dinucleotide phosphate and 160 mg of adenosine-5'-triphosphate per vial. The mixture is buffered and stabilized. For use in the Assay of lactulose it is diluted with water to 100 mL.

Nicotinic Acid—Use *Niacin* (USP monograph).

Ninhydrin, $C_9H_4O_3 \cdot H_2O$ —**178.14** [485-47-2]—Use ACS reagent grade.

Nitric Acid, HNO_3 —**63.01** [7697-37-2]—Use ACS reagent grade.

Nitric Acid, Diluted (10 percent HNO_3) [7697-37-2]—Dilute 143 mL of nitric acid with water to 1000 mL.

Nitric Acid, Fuming (90 Percent Nitric Acid), HNO_3 —**63.01** [7697-37-2]—Use ACS reagent grade Nitric Acid, 90 Percent.

Nitric Acid, Lead-Free—Use ACS reagent grade.

Lead—To 100 g add 0.1 g of anhydrous sodium carbonate and evaporate to dryness. Dissolve the residue in water, heating slightly, and dilute with the same solvent to 50.0 mL. Determine the lead content by atomic absorption spectrophotometry (see *Spectrophotometry and Light-Scattering* (851)) measuring the absorbance at 283.3 nm or 217.0 nm using a lead hollow-cathode lamp and an air-acetylene flame. It contains not more than 0.1 ppm of lead (Pb).

Nitric Oxide-Nitrogen Dioxide Detector Tube—A fuse-sealed glass tube so designed that gas may be passed through it and containing suitable absorbing filters and support media for an oxidizing layer and the indicator diphenyl benzidine.

Measuring range: 0.5 to 10 ppm.

[NOTE—Available from Draeger Safety, Inc., www.draeger.com, or from Gastec Corp., www.gastec.co.jp, distributed in the USA by www.nextteq.com.]

Nitrilotriacetic Acid, $\text{N}(\text{CH}_2\text{COOH})_3$ —**191.14** [139-13-9]—Use ACS reagent grade.

4'-Nitroacetophenone (*p'*-Nitroacetophenone), $\text{C}_8\text{H}_7\text{NO}_3$ —**165.15** [100-19-6]—Yellow crystals.

Assay—Inject an appropriate ether solution of the specimen (about 0.5 μL) into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a thermal conductivity detector, helium being used as the carrier gas. The following conditions have been found suitable: a 4-mm \times 1.8-m stainless steel column containing 10% phase G1 on support S1A; the injection port and detector temperatures are maintained at 200° and 300°, respectively; the column temperature is maintained at 170° and programmed to rise 3° per minute to 220°. The area of the 4'-nitroacetophenone peak is not less than 97% of the total peak area.

Melting range (741): between 78° and 80°.

o-Nitroaniline, $\text{NO}_2\text{C}_6\text{H}_4\text{NH}_2$ —**138.12** [88-74-4]—Orange-yellow crystals. Slightly soluble in cold water; soluble in hot water; freely soluble in alcohol and in chloroform. It forms water-soluble salts with mineral acids.

Melting range (741): between 71° and 72°.

p-Nitroaniline, $\text{NO}_2\text{C}_6\text{H}_4\text{NH}_2$ —**138.12** [100-01-6]—Bright yellow, crystalline powder. Insoluble in water; soluble in alcohol and in ether.

Melting range (741): between 146° and 148°.

Solubility—Separate 1-g portions dissolve in 30 mL of alcohol and in 40 mL of ether, respectively, to yield solutions that are clear or practically so.

Residue on ignition (Reagent test): not more than 0.2%.

Nitrobenzene, $\text{C}_6\text{H}_5\text{NO}_2$ —**123.11** [98-95-3]—Use ACS reagent grade.

p-Nitrobenzenediazonium Tetrafluoroborate, $\text{NO}_2\text{C}_6\text{H}_4\text{N}_2\text{BF}_4$ —**236.92** [456-27-9]—Yellow-gold crystals. Soluble in acetonitrile. [CAUTION—Shock-sensitive; keep refrigerated.]

Assay—Transfer about 30 mg, accurately weighed, to a low-actinic, 100-mL volumetric flask. Dissolve in 0.01 N hydrochloric acid, dilute with 0.01 N hydrochloric acid to volume, and mix. Using low-actinic glassware, dilute 2.0 mL of the resulting solution with spectrophotometric grade methanol to 50.0 mL. Measure the absorbance of this solution in a 1-cm cell at about 255 nm, using methanol as the blank. Calculate the absorptivity of the solution by dividing the measured absorbance by the concentration in g per mL. Calculate the assay value by the formula:

$$100a/59.4$$

in which *a* is the absorptivity of the solution: not less than 95.0% is found.

p-Nitrobenzyl Bromide, $\text{NO}_2\text{C}_6\text{H}_4\text{CH}_2\text{Br}$ —**216.03**—Almost white to pale yellow crystals, darkening on exposure to light. Practically insoluble in water; freely soluble in alcohol, in ether, and in glacial acetic acid. Store in tight, light-resistant containers.

Melting range (741): between 98° and 100°.

Solubility—Separate 200-mg portions yield clear solutions in 5 mL of alcohol and in 5 mL of glacial acetic acid.

Residue on ignition (Reagent test): negligible, from 200 mg.

4-(p-Nitrobenzyl)pyridine, $\text{C}_{12}\text{H}_{10}\text{N}_2\text{O}_2$ —**214.22** [1083-48-3]—Yellow crystals. Soluble in acetone. Use a suitable grade with a content of not less than 98%.

Nitromethane, CH_3NO_2 —**61.04** [75-52-5]—Use ACS reagent grade.

5-Nitro-1,10-phenanthroline, $\text{C}_{12}\text{H}_7\text{N}_3\text{O}_2$ —**225.20** [4199-88-6]—White powder. Soluble in water.

Melting range (741): between 198° and 200°.

Suitability as redox indicator—Dissolve 25 mg in a minimum volume of diluted sulfuric acid, add 10 mg of ferrous

sulfate, and dilute with water to 100 mL: the solution is deep red in color and exhibits an absorption maximum at 510 nm. To 1.0 mL of the solution add 1.0 mL of 0.01 M ceric sulfate: the red color is discharged.

Nitroso R Salt (1-Nitroso-2-naphthol-3,6-disodium Disulfonate), $\text{NOC}_{10}\text{H}_4\text{OH}(\text{SO}_3\text{Na})_2$ —**377.26** [525-05-3]—Yellow crystals or crystalline powder. One g dissolves in about 40 mL of water; insoluble in alcohol.

Sensitiveness—Dissolve 500 mg of sodium acetate in a solution of 0.4 mg of cobaltous chloride (0.1 mg of cobalt) in 5 mL of water. Add 1 mL of diluted acetic acid, and follow with 1 mL of a solution of the nitroso R salt (1 in 500): a red color, which is produced at once, persists when the solution is boiled with 1 mL of hydrochloric acid for 1 minute.

1-Nitroso-2-naphthol, $\text{C}_{10}\text{H}_7\text{NO}_2$ —**173.17** [131-91-9]—Brown to yellowish-brown powder. Insoluble in water; soluble in alcohol, in benzene, in ether, in carbon tetrachloride, and in acetic acid.

Assay—Transfer about 250 mg, previously dried over silica gel to constant weight and accurately weighed, to a glass-stoppered flask, and dissolve in 10 mL of sodium hydroxide solution (1 in 10). Cool the solution in an ice bath, add dilute sulfuric acid (1 in 6) until a slight, permanent precipitate is formed and the solution is slightly acid, then add 3 g of potassium iodide, shake to dissolve, add 20 mL of dilute sulfuric acid (1 in 6), immediately insert the stopper in the flask, and allow to stand in the dark for 2 hours. Titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. Perform a complete blank determination, and make any necessary correction. Each mL of 0.1 N sodium thiosulfate is equivalent to 8.66 mg of $\text{C}_{10}\text{H}_7\text{NO}_2$: not less than 95.0% is found.

Melting range (741): between 109° and 111°.

Residue on ignition (Reagent test): not more than 0.2%.

Nitrous Oxide Certified Standard [10024-97-2]—A container of 99.9% nitrous oxide. It is available from most suppliers of specialty gases.

Nonadecane, $\text{C}_{19}\text{H}_{40}$ —**268.52** [629-92-5]—White solid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a thermal conductivity detector, helium being used as the carrier gas. The following conditions have been found suitable: 3-mm \times 1.8-m stainless steel column containing 5% phase G2 on support S1AB; the injection port temperature is maintained at 330°; the detector temperature is maintained at 300°; and the oven temperature is held initially at 190° and allowed to rise gradually to 250°. The area of the nonadecane peak is not less than 99% of the total peak area.

Melting range (741): between 31.5° and 33.5°.

Nonanoic Acid, $\text{C}_9\text{H}_{18}\text{O}_2$ —**158.24** [112-05-0]—Clear, colorless to faint yellow liquid. Miscible with water and with methanol.

Assay—Accurately weigh about 500 mg, transfer to a suitable container, add 30 mL of water, and mix. Add 40 mL of water, and mix. Add phenolphthalein TS, and titrate with 0.1 N sodium hydroxide VS. Each mL of 0.1 N sodium hydroxide is equivalent to 15.82 mg of $\text{C}_9\text{H}_{18}\text{O}_2$: not less than 96.0% of $\text{C}_9\text{H}_{18}\text{O}_2$ is found.

Refractive index (831): about 1.432 at 20°.

Nonionic Wetting Agent—Use a suitable amphoteric surfactant.

[NOTE—A suitable grade is commercially available as Triton X-100 or Octoxynol 9.]

Nonoxynol-9 (Igepal CO-630, Semicid, Staycept, Tergitol TP-9, Sterox), $(\text{C}_2\text{H}_4\text{O})_n\text{C}_{15}\text{H}_{24}\text{O}$ —[26027-38-3]—Use a suitable grade.

1-Nonyl Alcohol (1-Nonanol), $\text{CH}_3(\text{CH}_2)_8\text{OH}$ —**144.25** [143-08-8]—Colorless liquid.

Assay—Not less than 97% of $C_9H_{20}O$ is found, a suitable gas chromatograph equipped with a flame-ionization detector and helium being used as the carrier gas at a flow rate of about 40 mL per minute. The following conditions have been found suitable: a 3.2-mm \times 1.83-m stainless steel column packed with 20% phase G16 on support S1A; the injection port, column, and detector temperatures are maintained at about 250°, 160°, and 310°, respectively.

Refractive index (831): between 1.432 and 1.434 at 20°.

***n*-Nonylamine** (1-Aminononane), $C_9H_{21}N$ —**143.27** [112-20-9]—Use a suitable grade.

Nonylphenol Polyoxyethylene Ether, $(CH_3)_3CCH_2C(CH_3)_2CH_2C_6H_4O(CH_2CH_2O)_xH$, where *x* is approximately 40 to 1900—2100 [9016-45-9]—White solid; melts at approximately 44°. Use a suitable grade.

Nonylphenoxypoly(ethyleneoxy)ethanol—Clear, viscous, pale yellow liquid. May exhibit slight solidification on cooling; warming with agitation will restore to original condition. Density: about 1.06. Soluble in alcohol, in xylene, and in water. Suitable for use in gas-liquid chromatography.

[NOTE—A suitable grade is "Igepal CO 710," available from General Aniline and Film Corp., 140 West 51st St., New York, NY 10020.]

Normal Butyl Alcohol—See *Butyl Alcohol*.

Normal Butyl Nitrite—See *n*-Butyl Nitrite.

Normal Butylamine—See *n*-Butylamine.

***n*-Octadecane**, $CH_3(CH_2)_{16}CH_3$ —**254.49** [593-45-3]—Use a gas chromatographic standard with a content of not less than 99.5%.

Octadecyl Silane [18623-11-5]—This reagent is formed *in situ* by reaction of the column support with a suitable silylating agent such as octadecyl trichlorosilane.

Octanesulfonic Acid Sodium Salt (*Sodium 1-octanesulfonate*), $C_8H_{17}NaO_3S$ —**216.27** [5324-84-5]—Use a suitable grade with a content of not less than 99.0%.

1-Octanol (*Alcohol C8*; *Capryl Alcohol*; *Octyl Alcohol*), $C_8H_{18}O$ —**130.23** [111-87-5]—Use ACS reagent grade.

Octanophenone, $C_{14}H_{20}O$ —**204.31** [1674-37-9]—Colorless liquid.

Assay—

MOBILE PHASE—Prepare a filtered and degassed mixture of acetonitrile and water (7:3).

PROCEDURE—Inject about 20 μ L into a suitable liquid chromatograph (see *Chromatography* (621)) equipped with a 254-nm detector and a 4.6-mm \times 15.0-cm column that contains packing L1. The flow rate is about 2 mL per minute. The area of the $C_{14}H_{20}O$ peak is not less than 99% of the total peak area.

Refractive index (831): 1.5043 at 20°.

Octoxynol 9—See *Nonionic Wetting Agent*.

(*p*-tert-Octylphenoxy) nonaethoxyethanol, $C_{34}H_{62}O_{11}$ —**646.85**—Use a suitable grade.

[NOTE—A suitable grade is available commercially as "Tergitol Nonionic NPX," and as "Triton N101," from reagent suppliers.]

(*p*-tert-Octylphenoxy)polyethoxyethanol—Use a suitable grade.

[NOTE—A suitable grade is available commercially as "Triton 100" from reagent suppliers.]

Octyl Sulfate, Sodium Salt, $C_8H_{17}O_4SNa$ —**232.27**—White powder.

Solubility—A 2-g portion dissolves in 100 mL of water.

Melting range (741): between 195° and 197°, with decomposition.

Odorless Absorbent Paper—See *Filter Paper, Quantitative*.

Olefin Detector Tube—A fuse-sealed glass tube so designed that gas may be passed through it and containing suitable absorbing filters and support media for the indicator in a stabilized form of permanganate.

Measuring range: 0.06 to 3.2 Vol.-% Propylene, 0.04 to 2.4 Vol.-% Butylene.

[NOTE—Available from Draeger Safety, Inc., www.draeger.com.]

Oligo-deoxythymidine—Polymeric length: 18. Use a suitable grade.

[NOTE—A suitable grade is available from BD Biosciences, www.bdbiosciences.com.]

Orange G (*the sodium salt of azobenzene-beta-naphthol disulfonic acid*), $C_{16}H_5N_2O_6Na$ —**452.37** [1936-15-8]—Orange to brick-red powder or dark red crystals. Readily soluble in water, yielding an orange-yellow solution; slightly soluble in alcohol; insoluble in ether and in chloroform. The addition of tannic acid TS to its 1 in 500 solution causes no precipitation (*acid color*). The addition of hydrochloric acid to a mixture of 500 mg of zinc dust and 10 mL of its 1 in 500 solution produces decolorization. When filtered, the colorless filtrate, on standing exposed to air, does not regain its original color (*presence of azo-group*). When heated, orange G does not deflagrate (distinction from *nitro colors*). The addition of barium or calcium chloride TS to a concentrated solution of orange G produces a colored, crystalline precipitate. The addition of hydrochloric acid to its 1 in 500 solution produces no change; the addition of sodium hydroxide TS to a similar solution produces a yellowish red to a Bordeaux color but no precipitation. Orange G dissolves in sulfuric acid with an orange to yellowish-red color. No change in color results upon diluting the solution cautiously with water.

Orcinol (*5-Methylresorcinol*), $C_7H_8O_2 \cdot H_2O$ —**142.15** [6153-39-5]—White to light tan crystals.

Assay—Transfer about 60 mg, accurately weighed, to a 100-mL volumetric flask, dissolve in methanol, dilute with methanol to volume, and mix. Transfer 5.0 mL of this solution to a 50-mL volumetric flask and dilute with methanol to volume, and mix. Using a suitable spectrophotometer, 1-cm cells, and methanol as the blank, record the absorbance of the solution at the wavelength of maximum absorbance at about 273 nm. From the observed absorbance, calculate the absorptivity (see *Spectrophotometry and Light-scattering* (851)): the absorptivity is not less than 13.2, corresponding to not less than 98% of $C_7H_8O_2 \cdot H_2O$.

Melting range (741): between 58° and 61°.

Orthophenanthroline—See *1,10-Phenanthroline*.

Osmium Tetroxide (*Osmic Acid*; *Perosmic Anhydride*), OsO_4 —**254.23** [20816-12-0]—Use ACS reagent grade.

Oxalic Acid, $H_2C_2O_4 \cdot 2H_2O$ —**126.07** [6153-56-6]—Use ACS reagent grade.

3,3'-Oxydipropionitrile, $O(CH_2CH_2CN)_2$ —**124.14** [1656-48-0]—Clear, colorless to slightly yellow liquid. Refractive index: about 1.446 at 20°.

Boiling range: between 174° and 176° at 10 mm of mercury.

Oxygen-Helium Certified Standard—A mixture of 1.0% oxygen in industrial grade helium. It is available from most suppliers of specialty gases.

Packings for High-Pressure Liquid Chromatography—See packings for high-pressure liquid chromatography in the *Chromatographic Reagents* section under *Chromatography* (621).

Palladium Catalyst—Use a suitable grade.

[NOTE—A suitable grade is available commercially as "Palladium Catalyst, Type I (5% Palladium on Calcium Carbonate)," from Engelhard Industries, Inc., fax number (864) 885-1375.]

Palladium Chloride, $PdCl_2$ —**177.33** [7647-10-1]—Brown, crystalline powder. Soluble in water, in alcohol, in acetone, and in diluted hydrochloric acid.

Assay—Dissolve 80 mg, accurately weighed, in 10 mL of diluted hydrochloric acid, dilute with water to 50 mL, and add 25 mL of a 1 in 100 solution of dimethylglyoxime in alcohol. Allow to stand for 1 hour, and filter. Check for complete precipitation with the dimethylglyoxime solution. Ignite the precipitate in a tared platinum crucible at 850° for 2 hours, cool, and weigh the palladium. The weight of the

residue is not less than 59.0% of the weight of the test specimen.

Palladous Chloride—See *Palladium Chloride*.

Pancreatic Digest of Casein (a bacteriological peptone; *Tryptone*)—A grayish-yellow powder, having a characteristic, but not putrescent, odor. Freely soluble in water; insoluble in alcohol and in ether.

Nitrogen content (Reagent test)—Determine by the Kjeldahl method: 9.0%–14.0% is found.

Loss on drying (731)—Dry it at 100° to constant weight: it loses not more than 7.0% of its weight.

Residue on ignition (281)—Ignite 500 mg with 1 mL of sulfuric acid: the residue weighs not more than 75 mg (15%).

Microbial content—NMT 10,000 cfu/g.

Bacteriological test—Prepare medium of the following composition:

2% of digest, 0.5% of sodium chloride, and 1.5% of agar in purified water.

Adjust with diluted hydrochloric acid or diluted sodium hydroxide to a pH of 7.2–7.4. Autoclave at 121° for 15 min.

Growth-supporting properties—Slants of the above medium, inoculated with *Escherichia coli* ATCC 25922, *Enterobacter aerogenes* ATCC 13048, *Salmonella enterica* ATCC 14028, *Pseudomonas aeruginosa* ATCC 27853, *Staphylococcus aureus* ATCC 25923, and *Staphylococcus epidermidis* ATCC 12228, show characteristic growth after incubation for 24 h.

The above medium, to which 5% of sheep blood or rabbit blood has been added, and which has been inoculated and poured into Petri dishes, shows characteristic alpha or beta zones around colonies of *Streptococcus pneumoniae* ATCC 6305 and *Streptococcus pyogenes* ATCC 49117, recognizable within 24 h and fully developed after 48 h of incubation.

The above medium, to which 10% of sheep blood or rabbit blood has been added, and which then has been heated to 80°–90° until the blood has turned chocolate-brown, permits the growth of *Neisseria gonorrhoeae* ATCC 19424 colonies within 48 h when incubated in an atmosphere containing 10% of carbon dioxide.

Pancreatin [8049-47-6]—Use a grade of pancreatin which meets the USP requirements for amylase, lipase, and protease activities specified for the official substance.

Papaic Digest of Soybean Meal—A soluble nutrient material prepared by the action of the enzyme papain on soybean meal followed by suitable purification and concentration. It contains fermentable carbohydrates.

Loss on drying (731)—Dry it at 100° to constant weight: it loses not more than 7.0% of its weight.

Residue on ignition (Reagent test)—Ignite 500 mg with 1 mL of sulfuric acid: the residue weighs not more than 75 mg (15.0%).

Coagulable protein—Heat a filtered solution (1 in 20) to boiling: no precipitate forms.

Microbial content—NMT 10⁴ cfu/g

Nitrogen content (Reagent test)—Determine by the Kjeldahl method, using a test specimen previously dried at 105° to constant weight: not less than 8.5% is found.

Paper, Odorless Absorbent—See *Filter Paper, Quantitative*.

Para-aminobenzoic Acid (*p*-Aminobenzoic Acid), H₂NC₆H₄COOH—**137.14** [150-13-0]—White or slightly yellow crystals or crystalline powder, becoming discolored on exposure to air or light. One g dissolves in 170 mL of water, in 9 mL of boiling water, in 8 mL of alcohol, and in 50 mL of ether. Freely soluble in solutions of alkali hydroxides and carbonates; soluble in warm glycerin; sparingly soluble in diluted hydrochloric acid; slightly soluble in chloroform. Store in tight, light-resistant containers.

Assay—Accurately weigh about 300 mg, previously dried at 105° for 2 hours, and transfer to a beaker or casserole.

Add 5 mL of hydrochloric acid and 50 mL of water, and stir until dissolved. Cool to about 15°, add about 25 g of crushed ice, and slowly titrate with 0.1 M sodium nitrite VS until a glass rod dipped into the titrated solution produces an immediate blue ring when touched to starch iodide paper. When the titration is complete, the endpoint is reproducible after the mixture has been allowed to stand for 1 minute. Each mL of 0.1 M sodium nitrite is equivalent to 13.71 mg of C₇H₇NO₂. Not less than 98.5% is found.

Melting range (741): between 186° and 189°.

Loss on drying (731)—Dry it at 105° for 2 hours: it loses not more than 0.2% of its weight.

Residue on ignition (Reagent test): not more than 0.1%.

Paraformaldehyde, (CH₂O)_n [30525-89-4]—Fine, white powder.

Assay—Transfer about 1 g, accurately weighed, to a 250-mL conical flask containing 50.0 mL of 1 N sodium hydroxide VS, and mix by swirling. Immediately, and slowly, add 50 mL of hydrogen peroxide TS, previously neutralized to bromothymol blue, through a small funnel placed in the neck of the flask. After the reaction moderates, rinse the funnel and inner wall of the flask with water, allow the solution to stand for 30 minutes, add bromothymol blue TS, and titrate the excess alkali with 1 N sulfuric acid VS. Each mL of 1 N sodium hydroxide is equivalent to 30.03 mg of HCHO: not less than 95% is found.

Residue on ignition: not more than 0.1%.

Solubility in ammonia—Dissolve 5 g in 50 mL of ammonia TS: a practically clear, colorless solution results.

Reaction—Shake 1 g with 20 mL of water for about 1 minute, and filter: the filtrate is neutral to litmus.

Pectate Lyase [9015-75-2]—An enzyme obtained from *Aspergillus* sp. Light brown, viscous liquid. Specific gravity is about 1.5. It is readily soluble in water. It is supplied at approximately 14 units per mL (at pH 8.0 in Tris-HCl buffer [50 mM of Tris(hydroxymethyl)aminomethane containing 1 mM of CaCl₂, pH 8.0] in a solution of 50% glycerol and 0.02% sodium azide. One unit is defined as the enzyme activity that produces 1 μmol of unsaturated product per minute.

Activity—

PECTIN SOLUTION—Transfer a quantity of Pectin, equivalent to 0.05 g on the dried basis, to a 100-mL volumetric flask. [NOTE—Pectin has a molecular weight of 103,000 Da; its degree of esterification (percentage of galacturonic acid groups substituted with methyl) is 12.] Moisten with 0.1 mL of 2-propanol. Add 50 mL of water to the flask, and mix the solution with a magnetic stirrer. Use 0.5 N sodium hydroxide to adjust the solution to a pH of 12. Stop the stirrer, and allow the solution to stand undisturbed at room temperature for 15 minutes. Adjust the solution with 0.5 N hydrochloric acid to a pH of 8.0. Dilute with water to volume.

TRIS BUFFER SOLUTION—Transfer 6.055 g of Tris(hydroxymethyl)aminomethane and 0.147 g of calcium chloride (CaCl₂ · H₂O) to a 1000-mL volumetric flask containing 950 mL of water, and mix. Adjust the solution with 1 N hydrochloric acid to a pH of 8.0. Dilute with water to volume.

DILUTED PECTATE LYASE—Transfer 0.5 mL of Pectate Lyase to a 50-mL volumetric flask, dilute with *Tris buffer solution* to volume, and mix.

PROCEDURE—Add the solutions set forth in the table below to quartz cuvettes.

Label	Tris buffer solution (mL)	Pectin solution (mL)	Diluted pectate lyase (mL)	Water (mL)
Enzyme blank	0.5	1.0	0	1.0
Test blank	0.5	0	0.5	1.5
Test solution	0.5	1.0	0.5	0.5

Perform the test on the solutions so obtained, using a suitable UV-Vis spectrophotometer (see *Spectrophotometry and Light-Scattering* (851)) and using water as the blank. Mix the solutions well at time 0, and immediately measure the absorbances at 235 nm. Record the value for the *Enzyme blank*, A_{0-EB} ; for the *Test blank*, A_{0-TB} ; and for the *Test solution*, A_{0-TS} . After incubation at room temperature for 30 minutes, determine the absorbance again at 235 nm for the *Enzyme blank*, A_{30-EB} ; for the *Test blank*, A_{30-TB} ; and for the *Test solution*, A_{30-TS} . One unit is defined as the enzymatic activity that produces 1 μmol of unsaturated product from pectin per minute. Calculate the Pectate Lyase activity, in units per mL, using the following formula:

$$50(10^3)[(A_{30-TS} - A_{30-EB} - A_{30-TB}) - (A_{0-TS} - A_{0-EB} - A_{0-TB})]/30\epsilon_{235}L$$

in which 50 is the volume, in mL, of *Diluted pectate lyase*; 10^3 is the unit conversion factor; 30 is the time, in minutes, of the reaction; ϵ_{235} is the molar extinction coefficient, in $\text{M}^{-1}\text{cm}^{-1}$, of the reaction product ($4600 \text{ M}^{-1} \text{ cm}^{-1}$); and L is the path length, in cm, of the reaction cuvette (1 cm). Alternatively, these solutions, after being mixed in the cuvettes, can be immediately measured at 235 nm continuously in a recording UV-Vis spectrophotometer set up for kinetic assays. The result is obtained by correcting the blank determination, using the *Enzyme blank* and the *Test blank*.

Penicillinase—See *Beta-lactamase*.

Pentadecane, $\text{C}_{15}\text{H}_{32}$ —**212.41** [629-62-9]—Colorless liquid.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μm layer of phase G2; the injection port temperature is maintained at 280°; the detector temperature is maintained at 300°; and the column temperature is maintained at 180° and programmed to rise 10° per minute to 280°. The area of the $\text{C}_{15}\text{H}_{32}$ peak is not less than 99% of the total peak area.

Refractive index (831): between 1.430 and 1.434 at 20°.

Add the following:

▲ **Pentafluoropropanoic Acid** (*Pentafluoropropionic Acid*), $\text{C}_3\text{HF}_5\text{O}_2$ —**164.03** [422-64-0]—Use a suitable grade with a content of NLT 97%.▲ USP36

Pentane (*n*-Pentane), C_5H_{12} —**72.15** [109-66-0]—Clear, colorless, flammable liquid. Very slightly soluble in water. Miscible with alcohol, with ether, and with many organic solvents. Specific gravity: about 0.62.

Boiling range (Reagent test)—Not less than 95% distills between 34° and 36°.

1-Pentanesulfonic Acid Sodium Salt—See *Sodium 1-Pentanesulfonate*.

2-Pentanone, $\text{C}_5\text{H}_{10}\text{O}$ —**86.13** [107-87-9]—Use a suitable grade.

Pepsin [9001-75-6]—Use *Pepsin (Enzyme Preparations)* FCC, having an activity of 1.0 to 1.17 Pepsin units per mg. Pepsin of higher activity may be reduced to this activity by admixture with pepsin of lower activity or with lactose.

Pepsin, Purified—A white or yellowish-white powder, spongy mass, or translucent scales or granules. Freely soluble in water, producing more or less opalescence; practically insoluble in alcohol, in chloroform, and in ether. Purified Pepsin used in the second tier of the *Dissolution* test has an activity that is determined by the following method.

Activity—

PEPSIN SOLUTION—Transfer about 2.5 mg of Purified Pepsin, accurately measured, to a 100-mL volumetric flask, dilute with 10 mM hydrochloric acid to volume, and mix. [NOTE—Prepare immediately before use.]

2.0% HEMOGLOBIN SOLUTION—Dissolve and dilute 2.5 g of bovine hemoglobin with water to 100 mL. Dilute 80 mL of this solution with 0.3 M hydrochloric acid to a volume of 100 mL.

TRICHLOROACETIC ACID SOLUTION—Dilute 5 g of trichloroacetic acid with water to 100 mL.

TEST SOLUTION—Transfer 5.0 mL of 2.0% *Hemoglobin solution* to a suitable container equilibrated at 37°. Add 1.0 mL of *Pepsin solution*, mix by swirling, and incubate at 37° for 10 minutes. Immediately add 10.0 mL of *Trichloroacetic acid solution*, mix by swirling, and incubate at 37° for 5 minutes. Pass through a filter having a 0.8- μm or finer porosity.

CONTROL SOLUTION—Transfer 5.0 mL of 2.0% *Hemoglobin solution* to a suitable container equilibrated at 37°. Mix by swirling, and incubate at 37° for 10 minutes. Immediately add 10.0 mL of *Trichloroacetic acid solution* and 1.0 mL of *Pepsin solution*, mix by swirling, and incubate at 37° for 5 minutes. Pass through a filter having a 0.8- μm or finer porosity.

PROCEDURE—Determine the absorbances of the *Test solution* and *Control solution*, in 1-cm cells, at a wavelength of about 280 nm, using water as the reference. Calculate the activity of the portion of Purified Pepsin taken by the formula:

$$10,000(A_U - A_C)$$

in which A_U and A_C are the absorbances of the *Test solution* and the *Control solution*, respectively.

Peptic Digest of Animal Tissue (a bacteriological peptone)—Tan powder, having a characteristic, but not putrescent, odor. Soluble in water; insoluble in alcohol and in ether. An autoclaved solution (2 in 100) is clear and is neutral or nearly so in its reaction.

Nitrogen content—Determine by the Kjeldahl method, using a test specimen previously dried at 105° to constant weight: between 9.0% and 14.0% of nitrogen is found.

Residue on ignition (281)—Ignite 500 mg with 1 mL of sulfuric acid: the residue weighs not more than 75 mg (15%).

Loss on drying (731)—Dry it at 100° to constant weight: it loses not more than 7.0% of its weight.

Coagulable protein—Heat a filtered solution (1 in 20) to boiling: no precipitate forms.

Microbial content—NMT 10^4 cfu/g

Bacteriological test (for growth promotion and freedom from fermentable carbohydrates)—

Medium: 2% of digest and sufficient phenol red TS to give a perceptible color in water; adjust the pH to 7.2–7.4.

Place 10 mL of *Medium* in test tubes containing a Durham fermentation tube. Autoclave at 121° for 15 min. After autoclaving and standing for 24 h, the *Medium* is clear.

In separate tubes for each organism, inoculate 10 mL of *Medium* with *Escherichia coli* ATCC 25922 and *Enterococcus faecalis* ATCC 12953. Incubate at $35 \pm 2^\circ$ for 48 h.

It meets the following criteria for bacteria-nutrient properties: *Escherichia coli* ATCC 25922 and *Enterococcus faecalis* ATCC 12953 growth evident, no acid or only a trace in the inner tube, and no gas produced after incubation at 48 h.

Peptone, Dried (*Meat Peptone*)—Reddish-yellow to brown powder, having a characteristic, but not putrescent, odor. Soluble in water, forming a yellowish-brown solution having a slight acid reaction; insoluble in alcohol and in ether.

Nitrogen content (Reagent test)—Determine by the Kjeldahl method, using a test specimen previously dried at 105° to constant weight: between 12% and 18% of nitrogen is found.

Residue on ignition (Reagent test)—Ignite 500 mg with 1 mL of sulfuric acid: the residue weighs NMT 75 mg (15.0%).

Loss on drying (731)—Dry it at 105° to constant weight: it loses not more than 7.0% of its weight.

Coagulable protein—Heat a filtered solution (1 in 20) to boiling: no precipitate forms.

Microbial content—NMT 10⁴cfu/g

Perchloric Acid (70 Percent Perchloric Acid), HClO₄—**100.46** [7601-90-3]—Use ACS reagent grade (containing between 69.0% and 72.0% of HClO₄).

Periodic Acid, H₅IO₆—**227.94** [10450-60-9]—White to pale yellow crystals. Very soluble in water. Undergoes slow decomposition to iodic acid. Use ACS reagent grade.

Petroleum Benzin—See *Hexane, Solvent*.

Phases for Gas Chromatography—See phases for gas chromatography in the *Chromatographic Columns* section under *Chromatography* (621).

Phenacetin [62-44-2]—Use a suitable grade.

1,10-Phenanthroline (*Orthophenanthroline*), C₁₂H₈N₂ · H₂O—**198.22** [5144-89-8]—Use ACS reagent grade.

o-Phenanthroline Monohydrochloride Monohydrate, C₁₂H₈N₂ · HCl · H₂O—**234.69** [3829-86-5]—Use a suitable grade.

Phenol [108-95-2]—Use ACS reagent grade.

Phenol Red, Sodium, C₁₉H₁₃O₅Na—**376.4** [34487-61-1]—Red to brown powder. Use ACS reagent grade.

Phenolsulfonphthalein—Use *Phenol Red* (see *Indicators* under *Indicators and Indicator Test Papers*).

Phenoxybenzamine Hydrochloride [*N*-(2-Chloroethyl)-*N*-(1-methyl-2-phenoxyethyl)benzylamine Hydrochloride], C₁₈H₂₂ClNO · HCl—**340.29** [63-92-3]—White, crystalline powder.

Melting range (741): between 137° and 140°.

Absorptivity—Its absorptivity, 1%, 1 cm, in the range of 272 nm to 290 nm, in chloroform solution is about 178.

3-Phenoxybenzoic Acid, C₁₃H₁₀O₃—**214.22** [3739-38-6]—Use a suitable grade.

Melting range (741): between 149° and 150°.

2-Phenoxyethanol, C₆H₅OCH₂CH₂OH—**138.16** [122-99-6]—Colorless, slightly viscous liquid. Soluble in water. Miscible with alcohol, with acetone, and with glycerin. Density: about 1.107.

Assay—To 2 g, accurately weighed, add 10 mL of a freshly prepared solution made by dissolving 25 g of acetic anhydride in 100 g of anhydrous pyridine. Swirl to mix the liquids, heat on a steam bath for 45 minutes, add 10 mL of water, heat for 2 additional minutes, and cool. Add 10 mL of normal butyl alcohol, shake vigorously, add phenolphthalein TS, and titrate with 1 N sodium hydroxide VS. Perform a blank test using the same quantities of the same reagents, and in the same manner, and make any necessary correction. Each mL of 1 N sodium hydroxide is equivalent to 138.2 mg of C₈H₁₀O₂. Not less than 99% is found.

Phenol—Add 0.2 mL of it to 20 mL of water, mix, and to 5 mL of the mixture add 0.2 mL of Millon's reagent. Warm the solution at 60° for 90 seconds, and allow to stand: no pink or red color is produced within 1 minute.

Phenyl Ether—See *Diphenyl Ether*.

Phenyl Isocyanate, C₆H₅NCO—**119.12** [103-71-9]—Clear, colorless to straw-yellow liquid of medium volatility. **[CAUTION—Phenyl Isocyanate is a violent lacrimator, and the vapor is highly toxic. Handle with care.]**

Assay—Transfer 250 mg, accurately weighed, to a glass-stoppered, 250-mL flask. Exercise care to avoid loss by volatilization, and avoid breathing the vapor. Add 20 mL of butylamine solution (25 g of butylamine diluted to 1000 mL with dioxane previously dried over potassium hydroxide pellets), insert the stopper in the flask, and allow to stand for 15 minutes. Add a few drops of methyl red TS and 25 mL of water, and titrate the excess amine with 0.1 N sulfuric acid VS. Perform a blank titration on 20 mL of the butylamine solution (see *Residual Titrations* (541)). Subtract the volume of 0.1 N sulfuric acid consumed in the test specimen titration from that consumed in the blank titration. Each mL of

0.1 N sulfuric acid, representing this difference, is equivalent to 11.91 mg of C₆H₅NCO: not less than 97.0% of C₆H₅NCO is found.

2-Phenylacetamide (*α-Phenylacetamide*), C₈H₉NO—**135.16** [103-81-1]—Bimorphous plates or leaflets. Slightly soluble in water. Use a suitable grade.

Melting range (741): between 156° and 158°.

dl-Phenylalanine, C₉H₁₁NO₂—**165.19** [150-30-1]—Use a suitable grade.

o-Phenylenediamine Dihydrochloride, C₆H₈N₂ · 2HCl—**181.1**—White powder.

Assay—When tested by thin-layer chromatography, with the use of plates coated with chromatographic silica gel mixture and a developing system consisting of a mixture of butyl alcohol, water, and acetic acid (12:5:3), and examined under short-wavelength UV light, a single spot is exhibited, with trace impurities.

p-Phenylenediamine Dihydrochloride—See *p-Phenylene-diamine Hydrochloride*.

p-Phenylenediamine Hydrochloride (1,4-Diaminobenzene Dihydrochloride), C₆H₈N₂ · 2HCl—**181.06**—White to pale tan crystals or crystalline powder, turning red on exposure to air. Freely soluble in water; slightly soluble in alcohol and in ether. Preserve in well-closed containers, protected from light.

Insoluble matter—Dissolve 1 g in 10 mL of water: the solution is clear and complete.

Molar absorptivity (see *Spectrophotometry and Light-scattering* (851))—Dissolve 60 mg in 100.0 mL of water, and mix. Pipet 2 mL of this solution into a 50-mL volumetric flask, dilute with pH 7 buffer solution to volume, and mix. The molar absorptivity of this solution, at 239 nm, is not less than 9000.

Phenylglycine (D(-)-2-Phenylglycine), (C₆H₅CH(NH₂)COOH)—**151.17** [875-74-1]—Use a suitable grade.

Phenylhydrazine, C₆H₅NHNH₂—**108.14** [100-63-0]—A colorless, or slightly yellowish, highly refractive liquid. **[NOTE—Protect from light, and distill under reduced pressure shortly prior to use.]**

Congearing temperature (651): not below 16°.

Insoluble matter—Shake 1 mL with 20 mL of diluted acetic acid: the resulting solution is clear or practically so.

Residue on ignition (Reagent test)—Ignite 1 mL with 0.5 mL of sulfuric acid: the residue weighs not more than 1 mg (0.1%).

Phenylhydrazine Hydrochloride, C₆H₅NHNH₂ · HCl—**144.60** [59-88-1]—White or yellowish crystals or powder. Soluble in water and in alcohol. Store in tight containers, protected from light. Use a suitable grade with a content of not less than 99%.

Phenylmethylsulfonyl Fluoride, C₇H₇FO₂S—**174.2** [329-98-6]—White to faint yellow powder. Use a suitable grade.

[NOTE—A suitable grade is available from Sigma-Aldrich, www.sigma-aldrich.com.]

3-Phenylphenol (*m*-Phenylphenol), C₆H₅C₆H₄OH—**170.21** [580-51-8]—White to off-white, crystalline powder.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm × 30-m capillary column coated with G1; the injection port temperature is maintained at 250°; the column temperature is maintained at 150° and programmed to rise 15° per minute to 250°; and the detector temperature is maintained at 310°. The area of the 3-phenylphenol peak is not less than 98% of the total peak area.

Melting range (741): between 76° and 79°.

Phloroglucinol, C₆H₃(OH)₃ · 2H₂O—**162.14** [6099-90-7]—White or yellowish-white crystals or a crystalline powder. Soluble in alcohol and in ether; slightly soluble in water.

Insoluble in alcohol—Dissolve 1 g in 20 mL of alcohol: a clear and complete solution results.

Melting range, Class Ia (741): between 215° and 219°.

Residue on ignition (Reagent test)—Ignite 1 g with 0.5 mL of sulfuric acid: the residue weighs not more than 1 mg (0.1%).

Diresorcinol—Heat to boiling a solution of 100 mg in 10 mL of acetic anhydride, cool the solution, and superimpose it upon 10 mL of sulfuric acid: no violet color appears at the zone of contact of the liquids.

Phloxine B (*Acid red 92; Eosin 10B; 2',4',5',7'-tetrabromo-4,5,6,7-tetrachlorofluorescein disodium salt*) $C_{20}H_2Br_4Cl_4Na_2O_5$ —**829.63** [18472-87-2]—Use a suitable grade with a dye content of not less than 80%, certified by the Biological Stain Commission.

Phosphatase Enzyme, Alkaline—Use a suitable grade from intestinal origin.

[NOTE—A suitable grade is available from Worthington Biochemical Corp., www.worthington-biochem.com.]

Phosphatic Enzyme—An enzyme preparation of microbial origin, high in both phosphatase and amylase activity, the former being the property that renders it suitable for use in the liberation of thiamine from its orthophosphate and pyrophosphate esters. Light cream-colored or slightly gray powder. Freely soluble in water. It hydrolyzes 300 times its weight of starch in 30 minutes.

Amylase activity—Place in a test tube 5 mL of a 1 in 50 solution of soluble starch in 0.2 M, pH 5 sodium acetate buffer (containing 1.6 g of anhydrous sodium acetate in each L and sufficient glacial acetic acid to adjust to a pH of 5), and add 4 mL of water. Mix, and place in a water bath at 40°. Add 1 mL of a solution containing 0.3 mg of the phosphatic enzyme, mix, and note the exact time. After 30 minutes remove 1.0 mL of the mixture, and add it to 5.0 mL of 0.0005 N iodine in a 20- × 150-mm test tube: a clear, red color results.

Phosphomolybdic Acid, approximately $20MoO_3 \cdot P_2O_5 \cdot 51H_2O$ —**3939.49** [11104-88-4]—Use ACS reagent grade.

Phosphoric Acid, H_3PO_4 —**98.00** [7664-38-2]—Use ACS reagent grade.

Phosphorous Acid (*Phosphonic Acid*), H_3O_3P —**82.00** [13598-36-2]—Use a suitable grade with a content of not less than 99%.

Phosphorus, Red, P—At. Wt. 30.97376—A dark red powder. Insoluble in water and in dilute acids; soluble in dehydrated alcohol.

Yellow phosphorus—Shake 20 g with 75 mL of carbon disulfide in a glass-stoppered vessel, and allow to stand in the dark overnight. Filter, and wash the residue with carbon disulfide until the filtrate, collected in a graduated cylinder, measures 100 mL. Evaporate the solvent to 10 mL by immersing the cylinder in hot water. Dip a strip of cupric sulfate test paper in the remaining solvent: no more color is produced than in a similar strip dipped into 10 mL of solution in carbon disulfide containing 3 mg of yellow phosphorus (0.015% as P).

Soluble substances—Digest 2 g with 30 mL of acetic acid on a steam bath for 15 minutes. Cool, dilute with water to 40 mL, and filter. Evaporate 20 mL of the filtrate on a steam bath, and dry at 105° for 2 hours: the residue weighs not more than 6 mg (0.6%).

Phosphorus Pentoxide (*Phosphoric Anhydride*), P_2O_5 —**141.94** [1314-56-3]—Use ACS reagent grade.

Phosphotungstic Acid, approximately $24WO_3 \cdot P_2O_5 \cdot 51H_2O$ —**6624.84**—White or yellowish-green crystals or a crystalline powder. Soluble in water, in alcohol, and in ether.

Insoluble matter (Reagent test): not more than 1 mg, from 5 g (0.02%).

Chloride (Reagent test)—One g shows not more than 0.3 mg of Cl (0.03%).

Nitrate—Dissolve 500 mg in 10 mL of water, and add about 10 mg of sodium chloride, 0.1 mL of indigo carmine TS, and 10 mL of sulfuric acid: the blue color does not disappear within 1 minute (about 0.01%).

Sulfate (Reagent test, *Method I*)—A 500-mg portion shows not more than 0.1 mg of SO_4 (0.02%).

o-Phthalaldehyde (*Phthalic Dicarboxaldehyde*), $C_6H_4(CHO)_2$ —**134.13** [643-79-8]—Use a suitable grade.
Phthalazine, $C_8H_6N_2$ —**130.15** [253-52-1]—Yellow to tan crystals.

Melting range (741): between 89° and 92°.

Phthalic Acid, $C_8H_6O_4$ —**166.13** [88-99-3]—Use ACS reagent grade.

Phthalic Anhydride, $C_8H_4O_3$ —**148.12** [85-44-9]—Use ACS reagent grade.

Phthalimide, $C_8H_5NO_2$ —**147.13** [85-41-6]—White powder.

Assay—

MOBILE PHASE—Prepare a mixture of isooctane and methyl-tert-butyl ether (88:12).

PROCEDURE—Inject about 20 μ L into a suitable liquid chromatograph (see *Chromatography* (621)) equipped with a 230-nm detector and a 4.6-mm × 15-cm column that contains packing L3. The flow rate is about 2 mL per minute. The area of the $C_8H_5NO_2$ peak is not less than 99% of the total peak area.

Melting range (741): between 233° and 235°, with decomposition.

2-Picoline, C_6H_7N —**93.13** [109-06-8]—Colorless to yellowish liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 2-mm × 2-m glass column packed with 20% liquid phase G16 on 80- to 100-mesh support S1C; the injection port temperature is maintained at 140°; the detector temperature is maintained at 300°; the column temperature is maintained at 90° and programmed to rise 3° per minute to 140°. The area of the C_6H_7N peak is not less than 98% of the total peak area.

Refractive index (831): 1.500 ± 0.002 at 20°.

Picric Acid (*2,4,6-Trinitrophenol; Trinitrophenol*), $C_6H_2(OH)(NO_2)_3$ —**229.10** [88-89-1]—Use ACS reagent grade.

Picrolonic Acid (*3-Methyl-4-nitro-1-(p-nitrophenyl)-5-pyrazolone*), $C_{10}H_8N_4O_5$ —**264.19** [550-74-3]—Yellow to brownish-yellow, crystalline powder. Slightly soluble in water; soluble in alcohol, in chloroform, in ether, in benzene, and in solutions of alkali hydroxides.

Melting range (741): between 115° and 117°.

Residue on ignition (Reagent test): negligible, from 200 mg.

Sensitiveness—Dissolve 25 mg in 10 mL of warm water containing 0.1 mL of glacial acetic acid, and filter the solution, if necessary. Dissolve 100 mg of calcium chloride in 250 mL of water, and mix. Heat 1 mL of the calcium chloride solution in a test tube to about 60°, then add to it 1 mL of the picrolonic acid solution: a bulky precipitate forms in 5 minutes or less.

Pipemidic Acid (*8-Ethyl-3,8-dihydro-5-oxo-2-(1-piperazinyl)pyrido[2,3-d]pyrimidine-6-carboxylic acid*), $C_{14}H_{17}N_5O_3$ —**303.3** [51940-44-4]—Use a suitable grade.

Piperazine (*Diethylenediamine*), $C_4H_{10}N_2 \cdot 6H_2O$ —**194.23**—Use a suitable grade.

Piperidine, $C_5H_{11}N$ —**85.15** [110-89-4]—Colorless liquid. Miscible with water and with alcohol. Specific gravity: about 0.860.

Congealing range (651): between 12° and 15°.

Boiling range (Reagent test)—Not less than 95% distills between 104° and 106°.

Refractive index: about 1.454.

Platinic Chloride (*Chloroplatinic Acid*), $\text{H}_2\text{PtCl}_6 \cdot 6\text{H}_2\text{O}$ —**517.90** [18497-13-7]—Use ACS reagent grade Chloroplatinic Acid.

Polydimethylsiloxane, *viscosity 0.65 centistokes* (*Hexamethyldisiloxane*), $(\text{CH}_3)_3\text{SiOSi}(\text{CH}_3)_3$ —**162.38** [107-46-0]—Liquid. Freezes at about 0°.

Refractive index (831): about 1.3770.

Specific gravity (841): about 0.760.

Polyethylene Glycol 200, $\text{H}(\text{OCH}_2\text{CH}_2)_n\text{OH}$ in which the average value of n is 4—average molecular weight 200 [25322-68-3]—Clear, colorless or almost colorless, viscous, hygroscopic liquid. Very soluble in acetone and in alcohol; practically insoluble in ether and in fatty oils. Use a suitable grade.

Refractive index (831): 1.4590 at 20°.

Density: 1.127 at 25°.

Viscosity: 4.3 centistokes at 98.9°.

Polyethylene Glycol 600 [25322-68-3]—A clear, practically colorless, viscous liquid condensation polymer represented by $\text{H}(\text{OCH}_2\text{CH}_2)_n\text{OH}$, in which n varies from 12 to 14. Its average molecular weight is about 600.

It meets the requirements of all of the tests under *Polyethylene Glycol* (NF monograph) except *Limit of ethylene glycol and diethylene glycol*.

Polyethylene Glycol 20,000 [25322-68-3]—Molecular weight range: 15,000–20,000. Hard, white, waxy solid, usually supplied in flake form. Soluble in water with subsequent gel formation.

Viscosity of 25% solution (911)—Add 50.0 g of test specimen to a 250-mL wide-mouth, screw-cap jar containing 150.0 g of water. Attach the cap securely to the jar, and roll on a mechanical roller until the test specimen is completely dissolved, in 2 to 4 hours. Allow the solution to stand until all air bubbles have disappeared. Another 2 to 4 hours may be required. Adjust the temperature of the solution to $37.8 \pm 0.1^\circ$, and determine the kinematic viscosity on a suitable viscometer of the Ubbelohde type. The viscosity is not less than 100 centistokes.

pH (791): between 6.5 and 8.0 in a solution (1 in 20). [NOTE—A five-fold dilution of the test solution prepared for the *Viscosity of 25% solution* test may be used.]

Residue on ignition (281): not more than 0.7%, the use of sulfuric acid being omitted.

Polyoxyethylene (23) Lauryl Ether (*Brij-35*)—Use a suitable grade.

[NOTE—A suitable grade is available commercially as “Brij-35.”]

Polyoxyethylene (20) Sorbitan Monolaurate [9005-64-5]—Viscous, light yellow to yellow-green liquid. Use a suitable grade.

Polysaccharide Molecular Weight Standards—Polymaltotriose polymers of different weight-average molecular weight, M_w , values ranging from 5,000 to 400,000 Da. [NOTE—A suitable set is available from Shodex (www.shodex.com) as Kit P-82.]

Polystyrene Cation-Exchange Resin—See *Cation-Exchange Resin, Polystyrene*.

Polytef—Use *Poly(tetrafluoroethylene)*.

Polyvinyl Alcohol, $(\text{C}_2\text{H}_4\text{O})_n$ [9002-89-5]—White powder. Soluble in water; insoluble in organic solvents.

pH (791): between 5.0 and 8.0, in a solution (1 in 25).

Loss on drying—Dry it at 110° to constant weight: it loses not more than 5% of its weight.

Residue on ignition: not more than 0.75%.

[NOTE—Suitable grades are available as catalog number U 232, from J.T. Baker Chemical Co., www.jtbaker.com.]

Potassium Acetate, $\text{KC}_2\text{H}_3\text{O}_2$ —**98.14** [127-08-2]—Use ACS reagent grade.

Potassium Alum—Use *Potassium Alum* [see *Potassium Alum* (USP monograph)].

Potassium Arsenate Monobasic, KH_2AsO_4 —**180.03** [7784-41-0]—Use a suitable grade with a content of NLT 98%.

Potassium Bicarbonate, KHCO_3 —**100.12** [298-14-6]—Use ACS reagent grade.

Potassium Biphosphate—See *Potassium Phosphate, Monobasic*.

Potassium Biphthalate (*Acid Potassium Phthalate; Phthalic Acid Monopotassium Salt; Potassium Hydrogen Phthalate Acidimetric Standard*), $\text{KHC}_6\text{H}_4(\text{COO})_2$ —**204.22** [877-24-7]—Use ACS reagent grade Potassium Hydrogen Phthalate, Acidimetric Standard.

Potassium Bisulfate, KHSO_4 —**136.17** [7646-93-7]—Fused, white, deliquescent masses or granules. Very soluble in water. When ignited, it evolves SO_3 and H_2O , changing first to potassium pyrosulfate, then to sulfate.

Acidity—Dissolve 4 g, accurately weighed, in 50 mL of water, add phenolphthalein TS, and titrate with 1 N alkali: it contains between 34% and 36%, calculated as H_2SO_4 .

Insoluble matter and ammonium hydroxide precipitate—Dissolve 10 g in 100 mL of water, add methyl red TS, render slightly alkaline with ammonia TS, boil for 1 minute, and digest on a steam bath for 1 hour. Pass through a tared filtering crucible, wash thoroughly, and dry at 105° for 2 hours: the precipitate weighs not more than 1 mg (0.01%).

For the following tests, prepare a *Test solution* as follows. Dissolve 6 g in 45 mL of water, add 2 mL of hydrochloric acid, boil gently for 10 minutes, cool, and dilute with water to 60 mL.

Heavy metals (Reagent test)—To 30 mL of *Test solution* add phenolphthalein TS, and neutralize with ammonia TS. Add 0.5 mL of glacial acetic acid, dilute with water to 40 mL, and add 10 mL of hydrogen sulfide TS: any brown color produced is not darker than that of a control containing 10 mL of *Test solution* and 0.02 mg of added Pb (0.001%).

Iron (241)—To 5 mL of *Test solution* add 2 mL of hydrochloric acid, and dilute with water to 47 mL: the solution shows not more than 0.01 mg of Fe (0.002%).

Potassium Bromate, KBrO_3 —**167.00** [7758-01-2]—Use ACS reagent grade.

Potassium Bromide, KBr —**119.00** [7758-02-3]—Use ACS reagent grade.

Potassium Carbonate—See *Potassium Carbonate, Anhydrous*.

Potassium Carbonate, Anhydrous, K_2CO_3 —**138.21** [584-08-7]—Use ACS reagent grade.

Potassium Chlorate, KClO_3 —**122.55** [3811-04-9]—Use ACS reagent grade.

Potassium Chloride, KCl —**74.55** [7447-40-7]—Use ACS reagent grade.

Potassium Chloroplatinate, K_2PtCl_6 —**485.99**—Heavy, yellow powder. Soluble in hydrochloric acid and in nitric acid.

Assay—Accurately weigh about 300 mg, transfer to a 600-mL beaker, add 20 mL of hydrochloric acid, and heat gently if necessary to achieve complete solution. Add zinc granules, slowly, until no more dissolves, then add 2 mL of hydrochloric acid, and digest for 1 hour on a steam bath to coagulate the reduced platinum. Add more acid, if necessary, to ensure that all of the zinc has dissolved. Filter through paper, rinsing the beaker with diluted hydrochloric acid until all of the precipitate is transferred to the filter, then wash with several small portions of water. Ignite the filter in a tared crucible at $800 \pm 25^\circ$ to constant weight.

Each mg of residue is equivalent to 1.0 mg of platinum. Not less than 40% is found.

Potassium Chromate, K_2CrO_4 —**194.19** [7789-00-6]—Use ACS reagent grade.

Potassium Cyanide, KCN —**65.12** [151-50-8]—Use ACS reagent grade.

Potassium Dichromate, $K_2Cr_2O_7$ —**294.18** [7778-50-9]—Use ACS reagent grade.

[NOTE—Potassium dichromate of a quality suitable as a primary standard is available from the National Institute of Standards and Technology, Washington, DC, www.nist.gov, as standard sample No. 136.]

Potassium Ferricyanide, $K_3Fe(CN)_6$ —**329.24** [13746-66-2]—Use ACS reagent grade.

Potassium Ferrocyanide, $K_4Fe(CN)_6 \cdot 3H_2O$ —**422.39** [14459-95-1]—Use ACS reagent grade.

Potassium Hyaluronate—White to cream-colored powder. Freely soluble in water. Store in a tight container, in a refrigerator.

Inhibitor content—Prepare as directed in the Assay under *Hyaluronidase for Injection* (USP monograph) a quantity of *Standard solution* containing 1 USP Hyaluronidase Unit in each mL, and a similar quantity of acetate-buffered *Standard solution* using as the solvent 0.1 M, pH 6 sodium acetate buffer (prepared by diluting the 0.2 M buffer prepared as directed below with an equal volume of water). Prepare from the potassium hyaluronate under test 10 mL of *Potassium hyaluronate stock solution*, and dilute 2 mL of it with the specified *Phosphate buffer solution* to make a *Hyaluronate solution*. In the same way, and concurrently, dilute a second 2-mL portion of the stock solution with 0.2 M, pH 6 sodium acetate buffer (containing 16.4 g of anhydrous sodium acetate and 0.45 mL of glacial acetic acid in each 1000 mL).

Place 0.50-mL portions of the *Hyaluronate solution* in each of four 16- × 100-mm test tubes, and place 0.50-mL portions of the acetate-buffered *Hyaluronate solution* in two similar tubes. To two of the four tubes containing *Hyaluronate solution* add 0.50 mL of *Diluent for hyaluronidase solutions*, prepared as directed in the Assay under *Hyaluronidase for Injection* (USP monograph). To the remaining two tubes, on a rigid schedule, at 30-second intervals, add 0.50 mL of *Standard solution*. Similarly, to the two tubes containing acetate-buffered *Hyaluronate solution* add at 30-second intervals 0.50-mL portions of acetate-buffered *Standard solution*. Then proceed as directed in the second paragraph for *Procedure*, beginning with "Mix the contents," as far as "Plot the average." The reduction in absorbance of acetate-buffered *Hyaluronate solution* is not less than 25% of that observed in the *Hyaluronate solution*.

Turbidity production—The average absorbance of the solutions in the two tubes containing *Hyaluronate solution* and *Diluent for hyaluronidase solutions* prepared in the test for *Inhibitor content* is not less than 0.26 at a wavelength of 640 nm in a suitable spectrophotometer using a 1-cm cell.

Potassium Hydrogen Sulfate, $KHSO_4$ —**136.17**—White crystals. Soluble in water.

Melting point (741): about 197°.

Potassium Hydroxide, KOH —**56.11** [1310-58-3]—Use ACS reagent grade.

Potassium Iodate, KIO_3 —**214.00** [7758-05-6]—Use ACS reagent grade.

Potassium Iodide, KI —**166.00** [7681-11-0]—Use ACS reagent grade.

Potassium Metabisulfite (*Potassium Disulfite*; *Potassium Pyrosulfite*), $K_2S_2O_5$ —**222.32** [16731-55-8]—Use a suitable grade with a content of not less than 98%.

Potassium Nitrate, KNO_3 —**101.10** [7757-79-1]—Use ACS reagent grade.

Potassium Nitrite, KNO_2 —**85.10** [7758-09-0]—Use ACS reagent grade.

Potassium Perchlorate, $KClO_4$ —**138.55** [7778-74-7]—Use ACS reagent grade.

Potassium Periodate (*Potassium meta-Periodate*), KIO_4 —**230.00** [7790-21-8]—Use ACS reagent grade.

Potassium Permanganate, $KMnO_4$ —**158.03** [7722-64-7]—Use ACS reagent grade.

Potassium Persulfate, $K_2S_2O_8$ —**270.32** [7727-21-1]—Use ACS reagent grade Potassium Peroxydisulfate.

Potassium Phosphate, Dibasic (*Dipotassium Hydrogen Phosphate*; *Dipotassium Phosphate*), K_2HPO_4 —**174.18** [7758-11-4]—Use ACS reagent grade.

Potassium Phosphate, Dibasic, Trihydrate (*Dipotassium Hydrogen Phosphate Trihydrate*; *Dipotassium Phosphate*), $K_2HPO_4 \cdot 3H_2O$ —**228.22** [16788-57-1]—Use a suitable grade with a content of NLT 99.0%.

Potassium Phosphate, Monobasic (*Potassium Biphosphate*; *Potassium Dihydrogen Phosphate*), KH_2PO_4 —**136.09** [7778-77-0]—Use ACS reagent grade.

[NOTE—Certified Potassium Dihydrogen Phosphate is available from the National Institute of Standards and Technology, Washington, DC, www.nist.gov, as standard sample No. 186.]

Potassium Phosphate, Tribasic, K_3PO_4 —**212.27** [7778-53-2]—Deliquescent, orthorhombic crystals. Use ACS reagent grade.

Potassium Pyroantimonate (*Potassium hexahydroxyantimonate*), $KSb(OH)_6$ —**262.90** [12208-13-8]—White crystals or a white, crystalline powder. Sparingly soluble in water. Use a suitable grade.

Potassium Pyrophosphate, $K_4P_2O_7$ —**330.34** [7320-34-5]—Colorless, deliquescent granules. Freely soluble in water; insoluble in alcohol.

Potassium Pyrosulfate [7790-62-7]—Usually available as a mixture of potassium pyrosulfate ($K_2S_2O_7$) and potassium bisulfate ($KHSO_4$). Use ACS reagent grade.

Potassium Sodium Tartrate, $KNaC_4H_4O_6 \cdot 4H_2O$ —**282.22** [6381-59-5]—Use ACS reagent grade.

Potassium Sulfate, K_2SO_4 —**174.26** [7778-80-5]—Use ACS reagent grade.

Potassium Tellurite (*Potassium Tellurate IV*), K_2TeO_3 —**253.79** [7790-58-1]—White, granular powder. Soluble in water. Its solution is alkaline.

Assay—Weigh accurately about 120 mg, transfer to a beaker, and dissolve in a mixture of 10 mL of nitric acid, 10 mL of sulfuric acid, and 25 mL of water. Heat to boiling, and boil until copious fumes of sulfur trioxide are evolved. Cool, cautiously add 100 mL of water, heat to boiling, add 6 g of sodium fluoride, and titrate the hot solution with 0.1 N potassium permanganate VS. Each mL of 0.1 N potassium permanganate is equivalent to 12.69 mg of K_2TeO_3 . Not less than 98% is found.

Chloride (Reagent test)—One g shows not more than 0.1 mg of Cl (0.01%).

Potassium Thiocyanate, $KSCN$ —**97.18** [333-20-0]—Use ACS reagent grade.

Potato Starch—See *Starch, Potato*.

Propionaldehyde, C_3H_6O —**58.08** [123-38-6]—Use a suitable grade.

Propionic Anhydride, $C_6H_{10}O_3$ —**130.14** [123-62-6]—Colorless liquid. Is decomposed by water. Soluble in methanol, in alcohol, in ether, and in chloroform.

Assay—Accurately weigh about 350 mg into a tared, glass-stoppered flask containing 50 mL of dimethylformamide previously neutralized to the thymol blue endpoint with 0.1 N sodium methoxide in methanol VS. Titrate with 0.1 N sodium methoxide in methanol VS to the thymol blue endpoint. Perform a blank determination, and make any

necessary correction. Each mL of 0.1 N sodium methoxide is equivalent to 13.014 mg of $C_6H_{10}O_3$. Not less than 97.0% is found.

Refractive index (831): between 1.4035 and 1.4045 at 20°.

Propiophenone, $C_9H_{10}O$ —**134.18** [93-55-0]—Use a suitable grade.

iso-Propyl Alcohol—See *Isopropyl Alcohol*.

n-Propyl Alcohol (1-Propanol), $CH_3CH_2CH_2OH$ —**60.10** [71-23-8]—Use ACS reagent grade.

Propylamine Hydrochloride (1-Propanamine hydrochloride; n-Propylamine hydrochloride), $C_3H_9N \cdot HCl$ —**95.57** [556-53-6]—Use a suitable grade with a content of not less than 99%.

Protein Molecular Weight Standard—Also known as protein molecular weight markers (for SDS-PAGE) and consists of a mixture of several proteins of well-defined molecular weights. The products are generally available in a suitable buffer containing a suitable reducing agent (generally, 100 mM DTT), a preservative (for example, sodium azide), and 50% glycerol to prevent freezing. Use a suitable grade. Store at -20°.

Protein Standard Solution (8 g/dL)—A solution containing 5 g of Albumin Human and 3 g of human gamma globulin per dL.

[NOTE—A suitable grade is available as Protein Standard Solution, catalog number 540-10, from Sigma-Aldrich, www.sigma-aldrich.com.]

Protocatechuic Acid (3,4-Dihydroxybenzoic acid), $C_7H_6O_4$ —**154.12** [99-50-3]—Use a suitable grade.

Pullulanase (Amylopectin-6-gluconohydrolase) [9075-68-7]—An enzyme obtained from *Klebsiella pneumoniae*. It contains not less than 30 units per mg of protein. One unit defined for enzymatic activity will liberate 1.0 μ mol of maltotriose (measured as glucose) from pullulan per minute at pH 5.0 at 30°. It can be suspended in 3.2 M ammonium sulfate solution, pH 6.2.

Measurement of relative pullulanase activity—

DETERMINATION OF PULLULANASE ACTIVITY—

Substrate—Dissolve pullulan¹ in water to make a 1.25% (w/v) solution. [NOTE—Add pullulan to the water. Clumping will occur if water is added to pullulan.]

Buffer solution A, pH 5.0—Add 0.1 M disodium phosphate (27 g of dibasic sodium phosphate in each L of the solution) to 0.1 M citric acid (21 g of citric acid in each L of the solution) to adjust pH to 5.0.

Buffer solution B, pH 6.0—Add diluted acetic acid to 1 M sodium acetate (136 g of sodium acetate in each L of solution) to adjust the pH to 6.0. Dilute with water to prepare the final buffer solution as 0.01 M acetic acid buffer, pH 6.0.

Somogyi reagent—Add 54 g of disodium phosphate heptahydrate or 28 g of anhydrous disodium hydrogen phosphate and 40 g of potassium sodium tartrate to about 650 mL of water or about 700 mL for anhydrous disodium hydrogen phosphate. Add 100 mL of 1 N sodium hydroxide to this solution and mix. Add 80 mL of 10% cupric sulfate to the solution, and mix. Heat until any solid is completely dissolved. Add 180 g of anhydrous sodium sulfate to the solution and adjust the volume to 1 L. Allow the solution to stand at room temperature for 1 or 2 days to let insoluble matter precipitate. Filter the solution with standard filter paper, and keep the solution in a brown bottle with a ground-glass stopper.

Nelson reagent—Dissolve 50 g of ammonium molybdate in 900 mL of water. Add 42 g of sulfuric acid, and mix. Dissolve 6 g of sodium arsenate or 3.6 g of monobasic potassium arsenate in 50 g of water. Allow the solution to stand in a brown bottle with a ground-glass stopper at 37° for 1 or 2 days.

¹A suitable supplier for pullulan is www.hayashibara-intl.com.

Glucose standard solution—Dry anhydrous glucose crystals under less than 50-mm Hg at 60° for 5 hours, and calculate the water content. Transfer 10.00 g of dried glucose to a 1-L volumetric flask, dissolve in and dilute with water to volume, and mix. Transfer 10.0 mL to a 1-L volumetric flask and dilute to volume with water. Each mL contains 100 μ g of glucose.

Pullulanase diluent—Dilute pullulanase with *Buffer solution B*, pH 6.0 to prepare a solution having the enzyme activity of about 0.2 units per mL. [NOTE—The measurement range is between 0.1 and 0.4 units per mL.] Record the dilution factor (F_{PD}). This diluent is used as a diluted enzyme solution.

Procedure—Transfer 4 mL of *Substrate* to a test tube and add 0.5 mL of *Buffer solution A*, pH 5.0, mix, and incubate at 30°. Add 0.5 mL of *Pullulanase diluent*, and mix thoroughly. After 30 seconds, transfer 1 mL of this solution to a test tube labeled as "Pullulan test solution 1", and add 2 mL of *Somogyi reagent*, and mix. After 30 minutes and 30 seconds, transfer 1 mL of the mixture of *Substrate* and *Pullulanase diluent* to a second test tube labeled as "Pullulan test solution 2", add 2 mL of *Somogyi reagent*, and mix. In a third test tube labeled as "Standard blank", mix 2 mL of *Somogyi reagent* and 1 mL of water. In a fourth test tube labeled as "Glucose standard solution", mix 2 mL of *Somogyi reagent* and 1 mL of *Glucose standard solution*, and add 1 mL of water. Incubate the fourth test tube in a boiling water bath for exactly 10 minutes. Remove the tube and allow it to cool in cold running water. Add 2 mL of *Nelson reagent*, mix well, and allow the solution to stand for at least 15 minutes. Add 5 mL of water to each of the four test tubes, and mix thoroughly. Determine the absorbance at 520 nm of the Standard blank, A_{blank} , of the *Glucose standard solution*, A_{Std} , of the Pullulan test solution 1, A_0 , and of the Pullulan test solution 2, A_{30} , using water as the blank. One unit is defined as the enzymatic activity that produces 1 μ mol of maltotriose (measured as glucose) from pullulan per minute. Calculate the pullulanase activity, PA, in units per mL, using the formula:

$$PA = [(A_{30} - A_0)/(A_{Std} - A_{blank})] \times 0.185 \times F_{PD}$$

MEASUREMENT OF PROTEIN AMOUNT (MEASURED AS ALBUMINOID AMOUNT) FOR THE CALCULATION OF SPECIFIC ACTIVITY—

Reagent A—Prepare a solution having known concentrations of about 0.1 N sodium hydroxide and about 0.2 M sodium carbonate.

Reagent B—Transfer 0.5 g of cupric sulfate and 1.0 g of sodium citrate dihydrate to a 100-mL volumetric flask, dissolve in and dilute with water to volume, and mix.

Lowry solution—Mix *Reagent A* and *Reagent B* at the proportion of 50:1.

Diluted Folin-Ciocalteu's phenol reagent (for albuminoid quantification)—Prepare a two-fold dilution of 2 N Folin-Ciocalteu's phenol reagent commercially available or prepare a solution by making an appropriate dilution from Folin-Ciocalteu Phenol TS (see *Method 2* in *Biotechnology-Derived Articles—Total Protein Assay* (1057)).

Bovine serum albumin standard stock solution—Transfer 0.05 g of bovine serum albumin to a 500-mL volumetric flask, dissolve in and dilute with water to volume, and mix. It contains 100 μ g of bovine serum albumin per mL.

Standard solutions—Using appropriate dilutions of *Bovine serum albumin standard stock solution* in water, prepare five *Standard solutions* having concentration equally spaced between 5 and 100 μ g of bovine serum albumin per mL.

Test solution—Dilute pullulanase with *Buffer solution B*, pH 6.0 in order to obtain a solution having a concentration between 60 and 70 μ g of albuminoid per mL. [NOTE—Water can be used as diluent.] Record the dilution factor, F_{TS} .

Blank solution—Use water.

Procedure—To 0.3 mL in separate tubes of the *Standard solutions*, the *Test solution*, and the *Blank solution*, add 3 mL of *Lowry solution*, and mix. Allow to incubate at room temperature for 10 minutes. Add 0.3 mL of *Diluted Folin-Ciocalteu's phenol reagent* to each tube, mix immediately, and allow to stand at room temperature for 60 minutes. Determine the absorbances of the *Standard solutions* and the *Test solution* at the wavelength of maximum absorbance at about 750 nm, using the *Blank solution* as the blank.

Calculation—[NOTE—The relationship of absorbance to protein concentration is nonlinear; however, if the standard curve concentration range is sufficiently small, it will approach linearity.] Using linear regression method, plot the absorbances of the *Standard solutions* versus the protein (bovine serum albumin) concentrations, in μg per mL, and determine the best fit curve. Using the plot, determine the concentration, $C_{\text{albuminoid}}$, in μg per mL, of protein (albuminoid amount) in the *Test solution*. Calculate the albuminoid concentration, in mg per mL, in the pullulanase taken by the formula:

$$C_{\text{protein}} = (C_{\text{albuminoid}} \times F_{\text{TS}})/1000$$

Calculate the specific activity, SA, in units per mg, of pullulanase using the formula:

$$\text{SA} = \text{PA}/C_{\text{protein}}$$

Pumice—A substance of volcanic origin consisting chiefly of complex silicates of aluminum and alkali metals. Occurs as very light, hard, rough, porous, gray masses, or as a gray-colored powder. Is insoluble in water and is not attacked by diluted acids.

Acid- and water-soluble substances—Boil 2.0 g of powdered pumice with 50 mL of diluted hydrochloric acid under a reflux condenser for 30 minutes. Cool, and filter. To half of the filtrate add 5 drops of sulfuric acid, evaporate to dryness, ignite, and weigh: the residue weighs not more than 60 mg (6.0%).

Purine, $\text{C}_5\text{H}_4\text{N}_4$ —**120.11** [120-73-0]—White to off-white powder.

Melting range (741): between 214° and 217°.

A single spot is exhibited when it is examined by thin-layer chromatography, with the use of plates coated with chromatographic silica gel mixture and a developing system consisting of butyl alcohol, water, and glacial acetic acid (60:25:15).

Putrescine Dihydrochloride, $\text{C}_4\text{H}_{12}\text{N}_2 \cdot 2\text{HCl}$ —**161.07** [333-93-7]—White, crystalline powder. Use a suitable grade.

Pyrazole, $\text{C}_3\text{H}_4\text{N}_2$ [288-13-1]—White to pale yellow crystals or crystalline powder. Soluble in water, in alcohol, and in ether.

Melting range (741): between 67° and 71°.

Pyrene, $\text{C}_{16}\text{H}_{10}$ —**202.25** [129-00-0]—White to light yellow crystals.

Assay—Transfer about 9 mg, accurately weighed, to a 100-mL volumetric flask, dissolve in methanol, dilute with methanol to volume, and mix. Transfer 2.0 mL of this solution to a 100-mL volumetric flask, dilute with methanol to volume, and mix. Using a suitable spectrophotometer, 1-cm cells, and methanol as the blank, record the absorbance of the solution at the wavelength of maximum absorbance at about 238 nm. From the observed absorbance, calculate the absorptivity (see *Spectrophotometry and Light-scattering* (851)): the absorptivity is not less than 432.9, corresponding to not less than 98% of $\text{C}_{16}\text{H}_{10}$.

Melting range (741): between 149° and 153° over a 2° range.

Pyridine, $\text{C}_5\text{H}_5\text{N}$ —**79.10** [110-86-1]—Use ACS reagent grade.

Pyridine, Dried [110-86-1]—Use ACS reagent grade.

Pyridoxal Hydrochloride, $\text{C}_8\text{H}_9\text{NO}_3 \cdot \text{HCl}$ —**203.62** [65-22-5]—White to slightly yellow crystals or crystalline powder. Gradually darkens on exposure to air or sunlight. One g dissolves in about 2 mL of water and in about 25 mL of alcohol. Insoluble in acetone, in chloroform, and in ether. Its solutions are acid (pH about 3).

Melting range (741): between 171° and 175° with some decomposition.

Residue on ignition (Reagent test): not more than 0.1%.

Loss on drying (731)—Dry it at 105° for 2 hours: it loses not more than 0.5% of its weight.

Nitrogen content (Reagent test)—Determine by the Kjeldahl method, using a test specimen previously dried at 105° for 2 hours: between 6.7% and 7.1% of N is found.

Chloride content—Accurately weigh about 500 mg, previously dried at 105° for 2 hours, and dissolve in 50 mL of water. Add 3 mL of nitric acid and 50.0 mL of 0.1 N silver nitrate VS, then add 5 mL of nitrobenzene, shake for about 2 minutes, add ferric ammonium sulfate TS, and titrate the excess silver nitrate with 0.1 N ammonium thiocyanate VS: each mL of 0.1 N silver nitrate is equivalent to 3.545 mg of Cl. Between 17.2% and 17.7% is found.

Pyridoxal 5-Phosphate, $4\text{-CHOC}_5\text{HN-2-CH}_3, 3\text{-OH}, 5\text{-CH}_2\text{PO}_4\text{H}_2 \cdot \text{H}_2\text{O}$ —**265.16** [41468-25-1]—Light yellow powder. Use a suitable grade.

Pyridoxamine Dihydrochloride, $\text{C}_8\text{H}_{12}\text{N}_2\text{O}_2 \cdot 2\text{HCl}$ —**241.11** [524-36-7]—White to slightly yellow crystals or crystalline powder. Gradually darkens on exposure to air or sunlight. One g dissolves in about 1 mL of water and in about 60 mL of alcohol. Insoluble in chloroform and in ether. Its solutions are acid.

Melting range (741): between 225° and 230°, with some decomposition.

Residue on ignition (Reagent test): not more than 0.15%.

Loss on drying (731)—Dry it at 105° for 2 hours: it loses not more than 0.5% of its weight.

Nitrogen content (Reagent test)—Determine by the Kjeldahl method, using a test specimen previously dried at 105° for 2 hours: between 11.3% and 11.8% of N is found.

Chloride content—Determine as directed in the test for *Chloride content* under *Pyridoxal Hydrochloride*: between 29.1% and 29.6% of Cl is found.

1-(2-Pyridylazo)-2-naphthol, $\text{C}_{15}\text{H}_{11}\text{N}_3\text{O}$ —**249.27** [85-85-8]—Stable, orange-red crystals. Soluble in alcohol and in hot solutions of dilute alkalis; slightly soluble in water.

Melting range (741): between 140° and 142°.

Sensitiveness—Add 0.1 mL of a 1 in 1000 solution of it in alcohol to a mixture of 10 mL of water and 1 mL of a buffer solution prepared by mixing 80 mL of 0.2 M acetic acid and 20 mL of sodium acetate solution (8.2 in 100), and mix. To this solution add 1 mL of a mixture of 1 mL of cupric sulfate TS and 2 mL of water, and mix: the color changes from yellow to red.

4-(2-Pyridylazo)resorcinol (PAR), $\text{C}_{11}\text{H}_9\text{N}_3\text{O}_2$, free acid; $\text{C}_{11}\text{H}_8\text{N}_3\text{NaO}_2$, monosodium salt—**215.21**, free acid—**237.21**, monosodium salt [1141-59-9], free acid; 16593-81-0, monosodium salt—Use ACS reagent grade.

3-(2-Pyridyl)-5,6-di(2-furyl)-1,2,4-triazine-5',5''-disulfonic Acid, Disodium Salt (3-(2-Pyridyl)-5,6-bis(5-sulfo-2-furyl)-1,2,4-triazine, Disodium Salt Hydrate), $\text{C}_{16}\text{H}_8\text{N}_4\text{Na}_2\text{O}_8\text{S}_2$ —**494.37** [79551-14-7]—Use a suitable grade.

[NOTE—A suitable grade is available as product number P4272 from Sigma-Aldrich, 1-800-558-9160; www.sigma-aldrich.com.]

Pyrogallol, $C_6H_3(OH)_3$ —**126.11** [87-66-1]—Use ACS reagent grade.

Pyrrole, C_4H_5N —**67.09** [109-97-7]—Clear liquid, colorless when freshly distilled, becoming yellow in a few days. Specific gravity: about 0.94. Insoluble in water; soluble in alcohol, in benzene, and in ether.

Boiling range (Reagent test)—Not less than 90% distills between 128° and 132°.

Pyruvic Acid, $CH_3COCOOH$ —**88.06** [127-17-3]—Colorless to light yellow liquid. Miscible with water, with alcohol, and with ether.

Refractive index (831): about 1.43 at 20°.

Assay—Accurately weigh about 1 g, transfer to a suitable container, and add 100 mL of water. Mix, add phenolphthalein TS, and titrate with 0.5 N sodium hydroxide VS. Each mL of 0.5 N sodium hydroxide is equivalent to 44.03 mg of $CH_3COCOOH$: not less than 98% of $CH_3COCOOH$ is found.

Quantitative Filter Paper—See *Filter Paper, Quantitative*.

Quinhydrone, $C_6H_4(OH)_2 \cdot C_6H_4O_2$ —**218.21** [106-34-3]—Green crystals having a metallic luster. Slightly soluble in cold water; soluble in hot water, in alcohol, and in ether.

Assay—Transfer about 450 mg, accurately weighed, to a glass-stoppered flask, add 50 mL of 1 N sulfuric acid and 3 g of potassium iodide, insert the stopper in the flask, and shake until dissolved. Titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. Each mL of 0.1 N sodium thiosulfate is equivalent to 5.405 mg of quinone ($C_6H_4O_2$). Between 49.0% and 51.0% is found.

Alcohol-insoluble matter—Dissolve 10 g in 100 mL of hot alcohol, filter through a suitable tared crucible of fine porosity, and wash with hot alcohol until the last washing is colorless. Dry at 105°, cool in a desiccator, and weigh: the residue weighs not more than 1.0 mg (0.010%).

Residue on ignition (Reagent test): not more than 0.050%, a 2.0-g test specimen being used. Save the residue.

Sulfate—Transfer 1 g to a platinum crucible, add 10 mL of hot water and 0.5 g of sodium carbonate, evaporate to dryness, and ignite, protected from the sulfur in the flame, until the residue is nearly white. Cool, add 20 mL of water and 1 mL of 30 percent hydrogen peroxide, boil gently for a few minutes, add 2 mL of hydrochloric acid, and evaporate on a steam bath to dryness. Cool, dissolve the residue in 20 mL of water, filter, and to the filtrate add 1 mL of 1 N hydrochloric acid and 3 mL of barium chloride TS: any turbidity produced within 10 minutes does not exceed that in a control containing 0.2 mg of added SO_4 and 0.5 mg of sodium carbonate, 1 mL of 30 percent hydrogen peroxide, and 2 mL of hydrochloric acid previously evaporated on a steam bath to dryness (0.02%).

Heavy metals—To the residue retained from the test for *Residue on ignition* add 2 mL of hydrochloric acid and 0.5 mL of nitric acid, and evaporate on a steam bath to dryness. Dissolve the residue in 30 mL of hot water containing 1 mL of 1 N hydrochloric acid, cool, dilute with water to 40 mL, and mix. Dilute 20 mL of this solution (retain the rest of the solution) with water to 25 mL, adjust to a pH between 3.0 and 4.0 by the addition of 1 N acetic acid or 6 N ammonium hydroxide as necessary, dilute with water to 40 mL, and add 10 mL of freshly prepared hydrogen sulfide TS: any brown color produced does not exceed that in a control containing 0.02 mg of added Pb (0.002%).

Iron (241)—To 10 mL of the solution retained from the test for *Heavy metals* add 2 mL of hydrochloric acid, and

dilute with water to 47 mL: the solution shows not more than 0.01 mg of Fe (0.002%).

Quinone—See *p-Benzoquinone*.

Rayon—Use *Purified Rayon* (General Monograph).

Direct Red 80, $C_{45}H_{26}N_{10}Na_6O_{21}S_6$ —**1373.07** [2610-10-8]—Red powder. Soluble in water; poorly soluble in alcohol. Use a suitable grade.

Red-Cell Lysing Agent—The reagent is available as a solution containing 0.33% potassium cyanide and 0.11% sodium nitroprusside and a quarternary ammonium salt as the surface active agent (5.5%).

[NOTE—The reagent is manufactured by Coulter Electronics Diagnostics, Hialeah, FL and is available from many suppliers under the name of Zapoglobin® (or Zap-oglobin®).]

Red Phosphorus—See *Phosphorus, Red*.

Resazurin (Sodium), $C_{12}H_6N_4NaO_4$ —**251.17** [62758-13-8]—A brownish-purple, crystalline powder. One g dissolves in 100 mL of water, forming a deep-violet-colored solution.

Hydrogen sulfide and other compounds containing the thiol group decolorize solutions of resazurin sodium, forming dihydroresorufin. When the decolorized solution is shaken in the presence of air, a rose color develops as a result of the formation of resorufin.

Retinyl Palmitate, $C_{36}H_{60}O_2$ —**524.9**—Yellow liquid.

Assay—

Mobile phase—Prepare a mixture of acetonitrile and tetrahydrofuran (55:15).

Procedure—Inject about 10 μ L into a suitable liquid chromatograph (see *Chromatography* (621)) equipped with a 320-nm detector and a 4.6-mm \times 15-cm column that contains packing L1. The flow rate is about 1 mL per minute. The area of the $C_{36}H_{60}O_2$ peak is not less than 93% of the total peak area.

Reverse Transcriptase—Use a suitable grade.

[NOTE—A suitable grade is available from BD Biosciences, www.bdbiosciences.com.]

Rhodamine B (Tetraethylrhodamine), $C_{28}H_{31}ClN_2O_3$ —**479.01** [81-88-9]—Green crystals or a reddish-violet powder. Very soluble in water, yielding a bluish-red solution that is strongly fluorescent when dilute. Very soluble in alcohol; slightly soluble in dilute acids and in alkali solutions. In strong acid solution, it forms a pink complex with antimony that is soluble in isopropyl ether.

Clarity of solution—Its solution (1 in 200) is complete and clear.

Residue on ignition (Reagent test)—Ignite 1 g with 1 mL of sulfuric acid: the residue weighs not more than 2 mg (0.2%).

Rhodamine 6G, $C_{28}H_{31}ClN_2O_3$ —**479.02** [989-38-8]—Use a suitable grade.

Ribonuclease Inhibitor—Use a suitable grade.

[NOTE—A suitable grade is available from BD Biosciences, www.bdbiosciences.com.]

Rose Bengal Sodium (Disodium Salt of 4,5,6,7-Tetrachloro-2',4',5',7'-tetraiodofluorescein), $C_{20}H_2Cl_4I_4Na_2O_5$ —**1017.64** [632-69-9]—Fine, rose-colored crystals or crystalline powder. Soluble in water. [NOTE—Render commercially available material suitably pure by the following treatment. Dissolve 8 g in 200 mL of water, and adjust to a pH between 10 and 11, using short-range pH indicator paper. Add 200 mL of acetone, while stirring gently, then add dilute hydrochloric acid (1 in 10), while continuing to stir, until the pH of the solution reaches 4.0. Add 400 mL more of water, with stirring, and continue the stirring for 5 minutes. Filter the crystals on a filtering funnel, and return the crystals to the beaker used for crystallization. Recrystallize three more times in the same manner, and dry the crystals at 110° for 12 hours. Store in an amber bottle in a refrigerator at a temperature between 2° and 8°. Prepare this reagent fresh monthly.]

Chromatographic purity—Dissolve 100 mg of rose bengal sodium, prepared as described above, in 100 mL of water,

and apply 10 μ L of the solution on suitable chromatographic paper. Develop the chromatogram by ascending chromatography, using a mixture of 1 part of dilute alcohol (1 in 4) and 1 part of dilute stronger ammonia water (1 in 12). Examine the chromatogram in daylight and under UV light (360 nm): no colored or fluorescent spot is visible other than the rose bengal sodium spot.

[NOTE—A suitable grade is available commercially as "Silica Gel H."]

Ruthenium Red (*Ruthenium Oxichloride, Ammoniated*), $\text{Ru}_2(\text{OH})_2\text{Cl}_4 \cdot 7\text{NH}_3 \cdot 3\text{H}_2\text{O}$ —**551.23** [11103-72-3]—A brownish-red to dark purple powder. Soluble in water.

S Designations—See supports for gas chromatography under *Reagents, Chromatographic Columns*.

Saccharose—Use *Sucrose* (NF monograph).

Safranin O [477-73-6]—Dark red powder consisting of a mixture of 3,7-diamino-2,8-dimethyl-5-phenylphenazinium chloride, $\text{C}_{20}\text{H}_{19}\text{ClN}_4$ —350.85, and 3,7-diamino-2,8-dimethyl-5-o-tolylphenazinium chloride, $\text{C}_{21}\text{H}_{21}\text{ClN}_4$ —364.88—Sparingly soluble in 70 percent alcohol yielding a clear red solution with a yellowish-red fluorescence.

Identification—

A: To 10 mL of a 0.5% w/v solution add 5 mL of hydrochloric acid: a bluish violet solution is produced.

B: To 10 mL of a 0.5% w/v solution add 5 mL of sodium hydroxide solution (1 in 5): a brownish-red precipitate is produced.

C: To 100 mg add 5 mL of sulfuric acid: a green solution is produced, which, on dilution, changes to blue and finally to red.

Absorption characteristics—Dissolve 50 mg in 250 mL of 50 percent alcohol. Dilute 3 mL of this solution with 50 percent alcohol to 200 mL. Determine the absorbance, in a 1-cm cell, with a suitable spectrophotometer. The absorbance maximum is in the range of 530 to 533 nm; the ratio $(P - 15)/(P + 15)$ is between 1.10 and 1.32, in which P is the wavelength of maximum absorbance.

[NOTE—A suitable grade is available as catalog number 10,214-8 from Sigma-Aldrich, www.sigma-aldrich.com.]

Salicylaldazine, $\text{C}_{14}\text{H}_{12}\text{N}_2\text{O}_2$ —**240.26**—Use a suitable grade or prepare as follows. Dissolve 300 mg of hydrazine sulfate in 5 mL of water, add 1 mL of glacial acetic acid and 2 mL of a freshly prepared 1 in 5 solution of salicylaldehyde in isopropyl alcohol, mix, and allow to stand until a yellow precipitate is formed. Extract the mixture with two 15-mL portions of methylene chloride. Combine the methylene chloride extracts, and dry over anhydrous sodium sulfate. Decant the methylene chloride solution, and evaporate it to dryness. Recrystallize the residue of salicylaldazine from a mixture of warm toluene and methanol (60:40) with cooling. Filter, and dry the crystals in vacuum.

Melting range (741°): between 213° and 219°, but the range between beginning and end of melting does not exceed 1°.

Chromatography—Proceed as directed in *Limit of hydrazine* under *Povidone*: the chromatogram shows only one spot.

Salicylaldehyde, (*2-Hydroxybenzaldehyde*), $2\text{-HOC}_6\text{H}_4\text{CHO}$ —**122.12** [90-02-8]—Clear, colorless to yellowish-green liquid. Specific gravity: about 1.17. Slightly soluble in water; soluble in alcohol and in ether. May contain a stabilizer.

Assay—When examined by gas-liquid chromatography, using suitable apparatus and conditions, it shows a purity of not less than 98%.

Sand, Standard 20- to 30-Mesh—Silica sand, composed almost entirely of naturally rounded grains of nearly pure quartz. Predominantly graded to pass an 850- μ m (No. 20) sieve (85 to 100 percentage passing) and be retained on a 600- μ m (No. 30) sieve (0 to 5 percentage passing).

[NOTE—A suitable grade is available as Ottawa Standard Sand from Thomas Scientific, 99 High Hill Road at I-295, P.O. Box 99, Swedesboro, NJ 08085-0099.]

Sand, Washed—It may be prepared as follows. Digest clean, hard sand at room temperature with a mixture of 1 part of hydrochloric acid and 2 parts of water (about 13% of HCl) for several days, or at an elevated temperature for several hours. Collect the sand on a filter, wash with water until the washings are neutral and show only a slight reaction for chloride, and finally dry. Washed sand meets the following tests.

Substances soluble in hydrochloric acid—Digest 10 g with a mixture of 10 mL of hydrochloric acid and 40 mL of water on a steam bath for 4 hours, replacing from time to time the water lost by evaporation. Filter, and to 25 mL of the filtrate add 5 drops of sulfuric acid, evaporate, and ignite to constant weight: the residue weighs not more than 8 mg (0.16%).

Chloride (Reagent test)—Shake 1 g with 20 mL of water for 5 minutes, filter, and add to the filtrate 1 mL of nitric acid and 1 mL of silver nitrate TS: any turbidity produced corresponds to not more than 0.03 mg of Cl (0.003%).

Sawdust, Purified—It may be prepared as follows. Extract sawdust in a percolator, first with sodium hydroxide solution (1 in 100), and then with dilute hydrochloric acid (1 in 100) until the acid percolate gives no test for alkaloid with mercuric-potassium iodide TS or with iodine TS. Then wash with water until free from acid and soluble salts, and dry. Purified sawdust meets the following test.

Alkaloids—To 5 g of purified sawdust contained in a flask add 50 mL of a mixture of 2 volumes of ether and 1 volume of chloroform and 10 mL of ammonia TS, and shake frequently for 2 hours. Decant 20 mL of the clear, ether-chloroform liquid, and evaporate to dryness. Dissolve the residue in 2 mL of dilute hydrochloric acid (1 in 12), and divide into two portions. To 1 portion add mercuric-potassium iodide TS, and to the other add iodine TS: no turbidity is produced in either portion.

Scandium Oxide, Sc_2O_3 —**137.91** [12060-01-1]—Fine, white powder.

Secondary Butyl Alcohol—See *Butyl Alcohol, Secondary*.

Selenious Acid (*Selenous Acid*), H_2SeO_3 —**128.97**

[7783-00-8]—Colorless or white crystals, efflorescent in dry air and hygroscopic in moist air. Soluble in water and in alcohol.

Assay—Accurately weigh about 100 mg, transfer to a glass-stoppered flask, and dissolve in 50 mL of water. Add 10 mL of potassium iodide solution (3 in 10) and 5 mL of hydrochloric acid, mix, insert the stopper in the flask, and allow to stand for 10 minutes. Dilute with 50 mL of water, add 3 mL of starch TS, and titrate with 0.1 N sodium thiosulfate VS until the color is no longer diminished, then titrate with 0.1 N iodine VS to a blue color. Subtract the volume of 0.1 N iodine solution from the volume of 0.1 N sodium thiosulfate to give the volume of 0.1 N thiosulfate equivalent to selenious acid. Each mL of 0.1 N sodium thiosulfate is equivalent to 3.225 mg of H_2SeO_3 ; not less than 93% is found.

Insoluble matter—Dissolve 1 g in 5 mL of water: the solution is clear and complete.

Residue on ignition (Reagent test): not more than 1.0 mg (0.01%), from 10 g.

Selenate and sulfate—Dissolve 500 mg in 10 mL of water, and add 0.1 mL of hydrochloric acid and 1 mL of barium chloride TS: no turbidity or precipitate is formed within 10 minutes.

Selenium, Se—**At. Wt. 78.96** [7782-49-2]—Dark-red amorphous, or bluish-black, crystalline powder. Soluble in solutions of sodium and potassium hydroxides or sulfides;

insoluble in water. Use a suitable grade with a content of not less than 99.99%.

Selenomethionine, $C_5H_{11}NO_2Se$ —**196.11**
[1464-42-2]—[CAUTION—Handle with care, as this reagent is highly toxic.]

Assay—Weigh accurately about 750 mg, dissolve in 100 mL of methanol, add crystal violet TS, and titrate with 0.1 N perchloric acid to a blue-green endpoint. Each mL of 0.1 N perchloric acid is equivalent to 19.61 mg of $C_5H_{11}NO_2Se$: between 97.0% and 103.0%, calculated on the as-is basis, is found.

Melting range (741): about 260°, with decomposition.

Nitrogen content (461)—Determine by the Kjeldahl method: between 6.8% and 7.4%, calculated on the as-is basis, is found.

Silica, Calcined Diatomaceous—See *Diatomaceous Silica, Calcined*.

Silica, Chromatographic, Silanized, Flux-Calcined, Acid-washed—Use a suitable grade.

[NOTE—Suitable grades are available commercially as “Aeropak 30,” “Diatoport S,” and “Gas-Chrom Z.”]

Silica Gel—An amorphous, partly hydrated SiO_2 occurring in glassy granules of varying size. When used as a desiccant, it frequently is coated with a substance that changes color when the capacity to absorb water is exhausted. Such colored products may be regenerated (i.e., may regain their capacity to absorb water) by being heated at 110° until the gel assumes the original color.

For use as a desiccant, use ACS Silica Gel Desiccant grade.

Silica Gel, Binder-Free—Silica gel for chromatographic use formulated without a binder, since only activated forms of the silica gel are used as the binding agent.

[NOTE—A suitable grade is available commercially as “Silica Gel H.”]

Silica Gel, Chromatographic—Use a suitable grade.

[NOTE—A suitable grade is available commercially as “Silica Gel G.”]

Silica Gel, Octadecylsilanized Chromatographic—Use a suitable grade.

[NOTE—A suitable grade is available commercially as “Reversed Phase Uniplates” from Analtech, www.analtech.com.]

Silica Gel, Porous—Use a grade suitable for high-pressure liquid chromatography.

[NOTE—A suitable grade for reverse phase high-pressure liquid chromatography is available as “LiChrosorb SI60, Reverse Phase.”]

Silica Gel-Impregnated Glass Microfiber Sheet—Use a suitable grade.

[NOTE—A suitable grade is available commercially as “Seprachrom” Chamber with Type SG ITLC, Product No. 51923, from Gelman Instrument Co., Ann Arbor, MI 48106.]

Silica Gel Mixture, Chromatographic—A mixture of silica gel with a suitable fluorescing substance.

[NOTE—A suitable grade is available commercially as “Silica Gel GF 254.”]

Silica Gel Mixture, Chromatographic, with Chemically Bound Amino Groups—Use a suitable grade.

Silica Gel Mixture, Dimethylsilanized, Chromatographic—Use a suitable grade.

[NOTE—A suitable grade is available as “Silica Gel 60 silanized RP-2 F₂₅₄,” from EMD Chemicals, www.emdchemicals.com.]

Silica Gel Mixture, Octadecylsilanized Chromatographic—Use a suitable grade.

[NOTE—A suitable grade is available commercially as KC-18F from Whatman Chemical Separation, Inc., 9 Bridewell Place, Clifton, NJ 07014.]

Silica Gel Mixture, Octylsilanized, Chromatographic—Use a mixture of RP-8 chromatographic silica gel with a suitable fluorescing substance agent.

Silica Microspheres—Use a suitable grade.

[NOTE—A suitable grade, in a controlled-diameter, spherical, porous form, is available commercially as “Zorbax Sil,” from Agilent, www.agilent.com.]

Siliceous Earth, Chromatographic—

For gas chromatography, use a specially prepared grade meeting the following general description: Purified siliceous earth of suitable mesh size that has been acid- and/or base-washed. It may or may not be silanized.

For column partition chromatography, it is essential that the material be free from interfering substances. If such interferences are known or thought to be present, purify the material as follows: Place a pledget of glass wool in the base of a chromatographic column having a diameter of 100 mm or larger, and add *Purified Siliceous Earth* (NF monograph) to a height equal to 5 times the diameter of the column. Add a volume of hydrochloric acid equivalent to one-third the volume of siliceous earth, and allow the acid to percolate into the column. Wash the column with methanol, using small volumes at first to rinse the walls of the column, and continue washing with methanol until the last washing is neutral to moistened litmus paper. Extrude the washed column into shallow dishes, heat on a steam bath to remove the excess methanol, and dry at 105° until the material is powdery and free from traces of methanol. Store the dried material in well-closed containers.

[NOTE—A suitable grade is “Chromosorb W-AW.”]

[NOTE—Suitable silanized grades for gas chromatography are “Gas Chrom Q,” and “Chromosorb W (AW-DMCS-treated).”]

[NOTE—A suitable grade for column chromatography is acid-washed “Celite 545,” available from Sigma-Aldrich, www.sigma-aldrich.com.]

Siliceous Earth, Chromatographic, Silanized—Place about 450 g of purified siliceous earth in a large, open, glass crystallizing dish in a vacuum desiccator containing 30 mL of a suitable silane, e.g., a mixture of 1 volume of dimethyldichlorosilane and 1 volume of trimethylchlorosilane, or a mixture of 1 volume of methyltrichlorosilane and 2 volumes of dimethyldichlorosilane. Apply vacuum intermittently for several hours, until no liquid silane remains. Float the treated purified siliceous earth on water, and gently agitate to allow any uncoated particles to sink. Skim the silanized material off the surface, wash it on a sintered-glass funnel with warm methanol until the filtrate no longer is acidic, and dry at 110°.

Silicic Acid, $SiO_2 \cdot xH_2O$ —(anhydrous) **60.08**

[1343-98-2]—White, amorphous powder. Insoluble in water and in acids; soluble in hot solutions of strong alkalis.

Residue on ignition (Reagent test): not less than 80.0%.

Nonvolatile with hydrofluoric acid—Heat 500 mg with 1 mL of sulfuric acid and 10 mL of hydrofluoric acid in a platinum crucible to dryness, and ignite to constant weight: the weight of the residue does not exceed 1.0 mg (0.2%).

Chloride (Reagent test)—One g shows not more than 0.05 mg of Cl (0.005%).

Sulfate (Reagent test)—Boil 2 g with 20 mL of dilute hydrochloric acid (1 in 40), filter, neutralize the filtrate with ammonia TS, and dilute with water to 20.0 mL. A 10-mL aliquot of the solution shows not more than 0.1 mg of SO_4 (0.01%).

Heavy metals (Reagent test)—Boil 2.5 g with 50 mL of dilute hydrochloric acid (1 in 10) for 5 minutes, filter while hot, and evaporate the filtrate on a steam bath to dryness. Take up the residue in 20 mL of dilute hydrochloric acid (1 in 500), digest for 5 minutes, cool, add water to make 100 mL, and filter. To 40 mL of the filtrate add 10 mL of hydrogen sulfide TS: any color produced is not darker than that produced by adding 10 mL of hydrogen sulfide TS to a control containing 0.03 mg of Pb (0.003%).

Iron (241)—To 20 mL of the filtrate obtained in the test for *Heavy metals* add 1 mL of hydrochloric acid, and dilute

with water to 47 mL: the solution shows not more than 0.015 mg of Fe (0.003%).

Silicic Acid—Impregnated Glass Microfilament Sheets with Fluorescent Indicator—Use a suitable grade.

[NOTE—One example of a suitable grade is "ITLC Type SAF" sheets, available from Gelman Instrument Co., 600 South Wagner Rd., Ann Arbor, MI 48106.]

Silicon Carbide, SiC—40.10 [409-21-2]—In small clean chips, suitable for use in promoting ebullition.

Silicone (75 Percent Phenyl, Methyl)—Use a suitable grade.

[NOTE—A suitable grade is available as "OV-25."]

Silicotungstic Acid, *n*-Hydrate (*Tungstosilicic Acid*), $\text{H}_4\text{Si}(\text{W}_3\text{O}_{10})_4 \cdot n\text{H}_2\text{O}$ —**2878.17** (anhydrous) [12520-88-6]—Green powder.

Assay—Dissolve about 1 g, accurately weighed, in 25 mL of dilute hydrochloric acid (1 in 5). Add 50 mL of a solution of 5 g of cinchonine in dilute hydrochloric acid (1 in 2). Warm on a steam bath for about 30 minutes. Cool, filter through a tared crucible, and ignite at 800° to constant weight. The weight of the residue multiplied by 1.047 is equal to the weight of silicotungstic acid dihydrate in the sample taken. Not less than 98% is found.

Silver Diethyldithiocarbamate, $(\text{C}_2\text{H}_5)_2\text{NCS}_2\text{Ag}$ —**256.14** [1470-61-7]—Use ACS reagent grade.

Silver Nitrate, AgNO_3 —**169.87** [7761-88-8]—Use ACS reagent grade.

Silver Oxide, Ag_2O —**231.74** [20667-12-3]—Brownish-black, heavy powder. Slowly decomposes on exposure to light. Absorbs carbon dioxide when moist. Practically insoluble in water; freely soluble in dilute nitric acid and in ammonia; insoluble in alcohol. Store in well-closed containers; do not expose to ammonia fumes or easily oxidizable substances.

Assay—Dissolve about 500 mg, previously dried at 120° for 3 hours and accurately weighed, in a mixture of 20 mL of water and 5 mL of nitric acid. Dilute with 100 mL of water, add 2 mL of ferric ammonium sulfate TS, and titrate with 0.1 N ammonium thiocyanate VS to a permanent reddish-brown color. Each mL of 0.1 N ammonium thiocyanate is equivalent to 11.59 mg of Ag_2O : not less than 99.7% of Ag_2O is found.

Loss on drying—Dry it at 120° for 3 hours: it loses not more than 0.25% of its weight.

Nitrate—To 500 mg add 30 mg of sodium carbonate and 2 mL of phenoldisulfonic acid TS, mix, and heat on a steam bath for 15 minutes. Cool, cautiously add 20 mL of water, render alkaline with ammonia TS, and dilute with water to 30 mL: any color produced by the test solution is not darker than that produced in a control containing 0.01 mg of NO_3 (0.002%).

Substances insoluble in nitric acid—Dissolve 5 g in a mixture of 5 mL of nitric acid and 10 mL of water, dilute with water to about 65 mL, and filter any undissolved residue on a tared filtering crucible (retain the filtrate for the test for *Substances not precipitated by hydrochloric acid*). Wash the crucible with water until the last washing shows no opalescence with 1 drop of hydrochloric acid, and dry at 105° to constant weight: the residue weighs not more than 1 mg (0.02%).

Substances not precipitated by hydrochloric acid—Dilute the filtrate obtained in the test for *Substances insoluble in nitric acid* with water to 250 mL, heat to boiling, and add, dropwise, sufficient hydrochloric acid to precipitate all of the silver (about 5 mL), avoiding any great excess. Cool, dilute with water to 300 mL, and allow to stand overnight. Filter, evaporate 200 mL of the filtrate in a suitable tared porcelain dish to dryness, and ignite: the residue weighs not more than 1.7 mg (0.05%).

Alkalinity—Heat 2 g with 40 mL of water on a steam bath for 15 minutes, cool, and dilute with water to 50 mL. Filter, discarding the first 10 mL of the filtrate. To 25 mL of the subsequent filtrate add 2 drops of phenolphthalein TS, and

titrate with 0.02 N hydrochloric acid VS to the disappearance of any pink color: not more than 0.20 mL is required (0.016% as NaOH).

β -Sitosterol, (22:23 *Dihydrostigmasterol*), $\text{C}_{29}\text{H}_{50}\text{O}$ —**414.7** [83-46-5]—White powder. Soluble in chloroform. Store in a freezer.

Specific rotation (781S): between -33° and -39° , determined in a solution containing 0.5 g of test specimen per mL of chloroform.

Water, Method I (921): not more than 6%.

Soda Lime—Use *Soda Lime* (NF monograph).

Sodium, Na—At. Wt. 22.98977 [7440-23-5]—Use ACS reagent grade.

Sodium Acetate, $\text{NaC}_2\text{H}_3\text{O}_2 \cdot 3\text{H}_2\text{O}$ —**136.08** [6131-90-4]—Use ACS reagent grade Sodium Acetate Trihydrate.

Sodium Acetate, Anhydrous, $\text{NaC}_2\text{H}_3\text{O}_2$ —**82.03** [127-09-3]—Use ACS reagent grade.

Sodium Alizarinsulfonate (*Alizarin Red S*; *Alizarin Sodium Monosulfonate*), $\text{C}_{14}\text{H}_7\text{NaO}_7\text{S} \cdot \text{H}_2\text{O}$ —**360.27**—Yellow-brown or orange-yellow powder. Freely soluble in water, with production of a yellow color; sparingly soluble in alcohol.

Sensitiveness—Add 3 drops of a solution of it (1 in 100) to 100 mL of water, and add 0.25 mL of 0.02 N sodium hydroxide: a red color is produced. Add 0.25 mL of 0.02 N hydrochloric acid: the original yellow color returns.

Sodium Ammonium Phosphate (*Microcosmic Salt*), $\text{NaNH}_4\text{HPO}_4 \cdot 4\text{H}_2\text{O}$ —**209.07**—Colorless crystals or white granules. Freely soluble in water; insoluble in alcohol. Effloresces in air and loses ammonia.

Insoluble matter and ammonium hydroxide precipitate—Dissolve 10 g in 100 mL of water, add 10 mL of ammonia TS, and heat on a steam bath for 1 hour. If any precipitate is formed, filter, wash well with water, and ignite: the ignited precipitate weighs not more than 1 mg (0.01%).

Chloride (Reagent test)—One g shows not more than 0.02 mg of Cl (0.002%).

Heavy metals—Dissolve 3 g in 25 mL of water, add 15 mL of 1 N sulfuric acid, then add 10 mL of hydrogen sulfide TS: any brown color developed in 1 minute is not darker than that of a control containing 3 mL of *Standard Lead Solution* (see (231)) and 0.5 mL of 1 N sulfuric acid (0.001%).

Nitrate—Dissolve 1 g in 10 mL of water, add 0.1 mL of indigo carmine TS, then add, with stirring, 10 mL of sulfuric acid: the blue color persists for 10 minutes (about 0.005%).

Sulfate (Reagent test, *Method II*)—Dissolve 10 g in 100 mL of water, add 5 mL of hydrochloric acid, and filter if necessary: the filtrate yields not more than 5 mg of residue (0.02%).

Sodium Arsenate (*Arsenic Acid Sodium Salt*), $\text{Na}_2\text{HASO}_4 \cdot 7\text{H}_2\text{O}$ —**312.01** [10048-95-0]—Use ACS reagent grade.

Sodium Arsenite, NaAsO_2 —**129.91** [7784-46-5]—White, crystalline powder. Soluble in water; slightly soluble in alcohol.

Assay—Transfer about 5.5 g, accurately weighed, to a 500-mL volumetric flask, dissolve in and dilute with water to volume, and mix. Pipet 25 mL of this solution into a suitable container, add 50 mL of water and 5 g of dibasic sodium phosphate, swirl to dissolve, and titrate with 0.1 N iodine VS, adding 3 mL of starch TS as the endpoint is approached. Each mL of 0.1 N iodine is equivalent to 3.746 mg of As. Between 57.0% and 60.5% is found (equivalent to 98.8% to 104.9% of NaAsO_2).

Chloride (Reagent test)—One g shows not more than 0.10 mg of Cl (0.01%).

Heavy metals—Dissolve 200 mg in 8 mL of dilute hydrochloric acid (3 in 8), and evaporate on a steam bath to dryness. Dissolve the residue in 5 mL of dilute hydrochloric acid (2 in 5), and again evaporate to dryness. Dissolve the residue in 10 mL of water, and add 2 mL of diluted acetic acid and 10 mL of hydrogen sulfide TS. Any brown color

produced is not darker than that of a control containing 0.01 mg of added Pb (0.005%).

Iron—Dissolve 1 g in 20 mL of dilute hydrochloric acid (1 in 5), and add, dropwise, a slight excess of bromine TS. Boil the solution to remove the excess bromine, cool, dilute with water to 40 mL, and add 10 mL of ammonium thiocyanate solution (3 in 10). Any red color produced is not darker than that of a control containing 0.02 mg of added Fe (0.02%).

Sulfide—Dissolve 1 g in 20 mL of water, and add 5 drops of lead acetate TS: no brown color is produced (about 0.0005%).

Sulfate (Reagent test, *Method II*)—Dissolve 5 g in 100 mL of water, add methyl orange TS, neutralize with 1 N hydrochloric acid, add 3 mL of the acid in excess, and filter: the filtrate yields not more than 3 mg of residue (0.02%).

Sodium Azide, NaN_3 —**65.01** [26628-22-8]—White powder.

Assay—[**CAUTION**—Sodium azide is a potent poison. Its conjugate acid HN_3 is more toxic than hydrogen cyanide and is readily liberated from neutral aqueous solutions. Contact of NaN_3 or hydrazoic acid (HN_3) with certain metals may produce explosive salts. Work in a well-ventilated hood, and handle the sample with care.] Dissolve about 100 mg, accurately weighed, in 50 mL of water, and add 3 drops of phenolphthalein. Adjust the pH, if necessary, to 7.0, and add 35.0 mL of 0.1 N perchloric acid. Pipet, while stirring, 2.5 mL of 1.0 M sodium nitrite into the solution, and stir for 15 seconds. Titrate rapidly to the phenolphthalein endpoint with 0.1 N sodium hydroxide. The endpoint should be reached in less than 4 minutes after addition of perchloric acid because HN_3 is readily volatile. Calculate the percentage of azide by the formula:

$$[(N_p)(V_p) - (N_s)(V_s)](65.01)(100)/2C$$

where N_p is the normality of perchloric acid solution; V_p is the volume of perchloric acid, in mL, taken; N_s is the normality of sodium hydroxide solution; V_s is the volume, in mL, of sodium hydroxide taken; 65.01 is the molecular weight of sodium azide; and C is the weight, in mg, of sodium azide. Not less than 98.5% of NaN_3 is found.

Sodium Bicarbonate, NaHCO_3 —**84.01** [144-55-8]—Use ACS reagent grade.

Sodium Biphenyl, $\text{C}_{12}\text{H}_9\text{Na}$ —**176.19**—Available as a solution in 2-ethoxyethyl ether, or in 1,2-dimethoxyethane (diethylene glycol diether).

Activity—Place 20 mL of dry toluene in a titration flask equipped with a magnetic stirring bar and a stopper having a hole through which the delivery tip of a weight buret may be inserted. Add a quantity of sodium biphenyl sufficient to produce a blue color in the mixture, and titrate with amyl alcohol, contained in a weight buret, to the disappearance of the blue color. (Disregard the amounts of sodium biphenyl and amyl alcohol used in this adjustment.) Weigh accurately the weight buret containing the amyl alcohol. Transfer the contents of a vial of well-mixed test specimen to the titration flask, and titrate quickly with the amyl alcohol to the disappearance of the blue color. Weigh the buret to determine the weight of amyl alcohol consumed, and calculate the activity, in mEq/vial, by the formula:

$$\text{Result} = 11.25W$$

in which W is the weight of amyl alcohol consumed. NLT 10% activity is found.

Iodine content—Add 10 mL to 5 mL of toluene contained in a 125-mL separator fitted with a suitable inert plastic stopcock, and shake vigorously for 2 min. Extract gently with three 10-mL portions of dilute phosphoric acid (1 in 3), combining the lower phases in a 125-mL iodine flask. Add sodium hypochlorite TS, dropwise, to the combined extracts until the solution turns brown, then add 0.5 mL in excess. Shake intermittently for 3 min, add 5 mL of freshly prepared, saturated phenol solution, mix, and allow to stand for 1 min, accurately timed. Add 1 g of potassium iodide, shake for 30 s, add 3 mL of starch TS, and titrate with 0.1 N sodium thiosulfate VS: NMT 0.1 mL of 0.1 N sodium thiosulfate is consumed.

[NOTE—A suitable grade is available as catalog number 277134 from www.sigma-aldrich.com or as catalog number 54101 from www.gfschemicals.com.]

Sodium Biphosphate, $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ —**137.99**—Use ACS reagent grade Sodium Phosphate, Monobasic.

Sodium Bisulfite [7631-90-5]—This reagent is usually a mixture of sodium bisulfite and sodium metabisulfite [7681-57-4]. Use ACS reagent grade Sodium Bisulfite.

Sodium Bitartrate, $\text{NaHC}_4\text{H}_4\text{O}_6 \cdot \text{H}_2\text{O}$ —**190.08** [6131-98-2]—White crystals or a crystalline powder. Soluble in cold water.

Assay—Dissolve about 500 mg, accurately weighed, in 30 mL of water, add phenolphthalein TS, and titrate with 0.1 N sodium hydroxide VS: each mL of 0.1 N sodium hydroxide is equivalent to 19.01 mg of $\text{NaHC}_4\text{H}_4\text{O}_6 \cdot \text{H}_2\text{O}$. Between 99% and 100.5% is found.

Insoluble matter (Reagent test): not more than 1 mg, from 10 g (0.01%).

Chloride (Reagent test)—One g shows not more than 0.2 mg of Cl (0.02%).

Heavy metals (Reagent test)—Dissolve 4 g in 25 mL of water, add 2 drops of phenolphthalein TS, and then add ammonia TS, dropwise, until the solution is slightly pink. Add 4 mL of 1 N hydrochloric acid, dilute with water to 40 mL, and add 10 mL of hydrogen sulfide TS: any brown color produced is not darker than that of a control containing 0.04 mg of added Pb (0.001%).

Sulfate (Reagent test, *Method I*)—One g shows not more than 0.2 mg of SO_4 (0.02%).

Sodium Borate (*Borax*; *Sodium Tetraborate*), $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$ —**381.37** [1303-96-4]—Use ACS reagent grade.

[NOTE—Certified Borax is available from the National Institute of Standards and Technology, Washington, DC, www.nist.gov, as standard sample No. 187.]

Sodium Borohydride, NaBH_4 —**37.83** [16940-66-2]—White, crystalline solid. Freely soluble in water; soluble (with reaction) in methanol. Its solutions are rapidly decomposed by boiling.

Assay—

POTASSIUM IODATE SOLUTION (0.25 N)—Dissolve 8.917 g, previously dried at 110° to constant weight and accurately weighed, in water to make 1000.0 mL.

PROCEDURE—Dissolve about 500 mg, accurately weighed, in 125 mL of sodium hydroxide solution (1 in 25) in a 250-mL volumetric flask, dilute with the sodium hydroxide solution to volume, and mix. Pipet 10 mL of the solution into a 250-mL iodine flask, add 35.0 mL of *Potassium iodate solution*, and mix. Add 2 g of potassium iodide, mix, add 10 mL of dilute sulfuric acid (1 in 10), insert the stopper in the flask, and allow to stand in the dark for 3 minutes. Titrate the solution with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. Calculate

the amount, in mg, of NaBH₄ in the specimen titrated by the formula:

$$[(35.0)(0.25)] - 0.1V)4.729$$

in which V is the volume, in mL, of 0.1 N sodium thiosulfate used in the titration. Not less than 98% is found.

Sodium Bromide, NaBr—**102.89** [7647-15-6]—Use ACS reagent grade.

Sodium Carbonate—Use *Sodium Carbonate, Anhydrous*.

Sodium Carbonate, Anhydrous, Na₂CO₃—**105.99** [497-19-8]—Use ACS reagent grade.

Sodium Carbonate, Monohydrate, Na₂CO₃ · H₂O—**124.00** [5968-11-6]—Use ACS reagent grade.

Sodium Chloride, NaCl—**58.44** [7647-14-5]—Use ACS reagent grade.

Sodium Chloride Solution, Isotonic—Use *Saline TS*.

Sodium Cholate Hydrate (3 α ,7 α ,12 α -trihydroxy-5 β -cholan-24-oic acid sodium salt; cholic acid sodium salt), C₂₄H₃₉NaO₅ · xH₂O—**430.55** (anhydrous) [206986-87-0]—It can be from ox or sheep bile. Use a suitable grade with a content of not less than 99%.

Sodium Chromate, Na₂CrO₄ · 4H₂O—**234.03** [7755-11-3]—Lemon-yellow crystals. Soluble in water.

Assay—Accurately weigh about 300 mg, and dissolve in 10 mL of water contained in a 500-mL flask. Add 3 g of potassium iodide and 10 mL of diluted sulfuric acid, and dilute with 350 mL of oxygen-free and carbon dioxide-free water. Titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. Each mL of 0.1 N sodium thiosulfate consumed is equivalent to 7.802 mg of Na₂CrO₄ · 4H₂O. Not less than 99% is found.

Insoluble matter (Reagent test): not more than 1 mg, from 20 g dissolved in 150 mL of water (0.005%).

Aluminum—Dissolve 20 g in 140 mL of water, filter, and add 5 mL of glacial acetic acid to the filtrate. Add stronger ammonia water until alkaline, and digest for 2 hours on a steam bath. Pass through hardened filter paper, wash thoroughly, ignite, and weigh: the residue weighs not more than 0.8 mg (0.002%).

Calcium—Determine as directed in the test for calcium for ACS reagent grade Potassium Chromate (0.005%).

Chloride—Determine as directed in the test for chloride for ACS reagent grade Potassium Chromate (about 0.005%).

Sulfate—Determine as directed in the test for sulfate for ACS reagent grade Potassium Dichromate, but add 4.5 mL of hydrochloric acid to the water used to dissolve the test specimen: the residue weighs not more than 2.4 mg (0.01%).

Sodium Chromotropate—See *Chromotropic Acid*.

Sodium Citrate Dihydrate (2-Hydroxy-1,2,3-propanetricarboxylic Acid, Trisodium Salt, Dihydrate), Na₃C₆H₅O₇ · 2H₂O—**294.10** [6132-04-3]—Use ACS reagent grade.

Sodium Cobaltinitrite, Na₃Co(NO₂)₆—**403.94** [13600-98-1]—Use ACS reagent grade.

Sodium Cyanide, NaCN—**49.01** [1433-33-9]—Use ACS reagent grade.

Sodium 1-Decanesulfonate (1-Decanesulfonic Acid Sodium Salt), C₁₀H₂₁NaO₃S—**244.33** [13419-61-9]—Use a suitable grade for ion pair chromatography with a content of not less than 99.0%.

Sodium Desoxycholate—Use *Bile Salts*.

Sodium Dichromate, Na₂Cr₂O₇ · 2H₂O (for chromic acid cleaning mixture)—**298.00** [7789-12-0]—Use ACS reagent grade.

Sodium Diethyldithiocarbamate, (C₂H₅)₂NCS₂Na · 3H₂O—**225.31** [20624-25-3]—Use ACS reagent grade.

Sodium 2,2-dimethyl-2-silapentane-5-sulfonate—See *Sodium 3-(trimethylsilyl)-1-propane sulfonate*.

Sodium Dithionite—Use *Sodium Hydrosulfite*.

Sodium Dodecyl Sulfate (*Sodium Lauryl Sulfate*), C₁₂H₂₅SO₄Na—**288.38** [151-21-3]—Light yellow, crystalline powder.

Sodium Ferrocyanide, Na₄Fe(CN)₆ · 10H₂O—**484.06** [13601-19-9]—Yellow crystals or granules. Freely soluble in water.

Assay—Dissolve 2 g, accurately weighed, in 400 mL of water, add 10 mL of sulfuric acid, and titrate with 0.1 N potassium permanganate VS. Each mL of 0.1 N potassium permanganate is equivalent to 48.41 mg of Na₄Fe(CN)₆ · 10H₂O. Not less than 98% is found.

Insoluble matter (Reagent test): not more than 1 mg, from 10 g (0.01%).

Chloride (Reagent test)—Dissolve 1 g in 75 mL of water, add a solution prepared by dissolving 1.2 g of cupric sulfate in 25 mL of water, mix, and allow to stand for 15 minutes. To 20 mL of the decanted, clear liquid add 2 mL of nitric acid and 1 mL of silver nitrate TS: any turbidity produced does not exceed that of a control containing 0.02 mg of Cl, 2 mL of nitric acid, 1 mL of silver nitrate TS, and sufficient cupric sulfate to match the color of the Test solution.

Sulfate—Dissolve 5 g in 100 mL of water without heating, filter, and to the filtrate add 0.25 mL of glacial acetic acid and 5 mL of barium chloride TS: no turbidity is produced in 10 minutes (about 0.01% as SO₄).

Sodium Fluorescein, C₂₀H₁₀Na₂O₅—**376.28**—Orange-red, hygroscopic powder. Freely soluble in water; slightly soluble in alcohol. Its water solution is yellowish red in color and exhibits a strong yellowish green fluorescence that disappears when the solution is acidified and reappears when the solution is neutralized or made basic.

Loss on drying (731)—Dry it at 120° to constant weight: it loses not more than 7.0% of its weight.

Sodium Fluoride, NaF—**41.99** [7681-49-4]—Use ACS reagent grade.

Sodium Glycocholate, C₂₆H₄₂NNaO₆—**487.60** [863-57-0]—White to tan powder. Is hygroscopic. Freely soluble in water and in alcohol.

Specific rotation (781): between +28° and +31°, calculated on the dried basis (it is rendered anhydrous by drying at 100° for 2 hours), determined at 20° in a solution containing 10 mg per mL.

Nitrogen, Method I (461): between 2.6% and 3.2% of N is found, calculated on the dried basis.

Sodium 1-Heptanesulfonate (1-Heptanesulfonic Acid Sodium Salt), C₇H₁₅NaO₃S—**202.25** [22767-50-6]—Use a suitable grade.

Sodium 1-Heptanesulfonate Monohydrate, C₇H₁₅NaO₃S · H₂O—**220.26** [22767-50-6]—Use a suitable grade.

Sodium 1-Hexanesulfonate (1-Hexanesulfonic Acid Sodium Salt), C₆H₁₃NaO₃S—**188.22** [2832-45-3]—Use a suitable grade.

Sodium 1-Hexanesulfonate Monohydrate, C₆H₁₃NaO₃S · H₂O—**206.23** [2832-45-3]—Use a suitable grade.

Sodium Hydrogen Sulfate (*Sodium Bisulfate*), NaHSO₄—**120.06** [7681-38-1]—Freely soluble in water; very soluble in boiling water. It decomposes in alcohol into sodium sulfate and free sulfuric acid. Use a suitable reagent grade.

Melting point (741): about 315°.

Sodium Hydrosulfite (*Sodium Dithionite*), Na₂S₂O₄—**174.11** [7775-14-6]—White or grayish-white crystalline powder. Soluble in water; slightly soluble in alcohol. Gradually oxidizes in air, more readily when in solution, to bisulfite, acquiring an acid reaction. Is affected by light.

Assay—Accurately weigh about 1 g, dissolve it in a mixture of 10 mL of formaldehyde TS and 10 mL of water contained in a small glass-stoppered flask, and allow to stand for 30 minutes with frequent agitation. Transfer the solution to a 250-mL volumetric flask, add 150 mL of water and 3 drops of methyl orange TS, and then add, dropwise, 1 N sulfuric acid to a slightly acid reaction. Dilute with water to 250 mL, and mix. To 50.0 mL of the dilution add 2 drops of phenolphthalein TS and just sufficient 0.1 N sodium hydroxide to produce a slight, pink color, then titrate with 0.1 N iodine, adding 3 mL of starch TS as the indicator. Then discharge the blue color of the solution with 1 drop of 0.1 N sodium thiosulfate, and titrate with 0.1 N sodium hydroxide VS to a pink color: each mL of 0.1 N sodium hydroxide is equivalent to 3.482 mg of $\text{Na}_2\text{S}_2\text{O}_4$. Not less than 88% is found.

Sulfide—Add sodium hydroxide solution (1 in 10) to lead acetate TS until the precipitate dissolves. Add 5 drops of this solution to a solution of 1 g of the sodium hydrosulfite in 10 mL of water: no immediate darkening is observed.

Heavy metals—Dissolve 1 g in 10 mL of water, add 10 mL of hydrochloric acid, and evaporate on a steam bath to dryness. Dissolve the residue in 20 mL of water and 0.5 mL of diluted hydrochloric acid, filter, and add to the filtrate 10 mL of hydrogen sulfide TS: no darkening is produced. Render the solution alkaline with ammonia TS: a slight, greenish color may be produced, but not a dark or white precipitate.

Suitability for riboflavin assay—To each of 2 or more tubes add 10 mL of water and 1.0 mL of a standard riboflavin solution containing 20 µg of riboflavin in each mL, and mix. To each tube add 1.0 mL of glacial acetic acid, mix, add with mixing, 0.5 mL of potassium permanganate solution (1 in 25), and allow to stand for 2 minutes. Then to each tube add, with mixing, 0.5 mL of hydrogen peroxide TS: the permanganate color is destroyed within 10 seconds. Shake the tubes vigorously until excess oxygen is expelled. If gas bubbles remain on the sides of tubes after foaming has ceased, remove the bubbles by tipping the tubes so that the solution flows slowly from end to end. In a suitable fluorometer, measure the fluorescence of the solution. Then add, with mixing, 8.0 mg of sodium hydrosulfite: the riboflavin is completely reduced in not more than 5 seconds.

Sodium Hydroxide, NaOH —**40.00** [1310-73-2]—Use ACS reagent grade.

Sodium Hypochlorite Solution [7681-52-9]—A solution of sodium hypochlorite (NaOCl) in water. Usually yellow to yellowish-green in color. Has an odor of chlorine. Is affected by light and gradually deteriorates. Store it in light-resistant containers, preferably below 25°. [**CAUTION**—This solution is corrosive and may evolve gases that are corrosive and toxic. It is a powerful oxidant that can react violently with reducing agents. Is irritating and corrosive to skin and mucous membranes.]

Assay—Transfer about 3 mL to a tared, glass-stoppered iodine flask, and weigh accurately. Add 50 mL of water, 2 g of potassium iodide, and 10 mL of acetic acid, insert the stopper in the flask, and allow to stand in the dark for 10 minutes. Remove the stopper, rinse the walls of the flask with a few mL of water, and titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is neared. Each mL of 0.1 N sodium thiosulfate consumed is equivalent to 3.723 mg of NaOCl : not less than 5.25% is found. If it is desired to calculate the percentage of available chlorine, note that each mL of 0.1 N sodium thiosulfate consumed is equivalent to 3.545 mg of available chlorine.

Calcium—Transfer 10.0 g to a 150-mL beaker, dissolve in 10 mL of water, and add 5 mL of hydrochloric acid and 2 g of potassium iodide. Heat the mixture for 5 minutes, cool, and add 2 mL of 30 percent hydrogen peroxide. Evaporate to dryness, cool, and add 2 mL of hydrochloric acid and 2 mL of 30 percent hydrogen peroxide. Rinse the inner walls of the beaker with a few mL of water, and evaporate to

dryness. Take up the residue in 20 mL of water, and filter if necessary. To the filtrate add ammonium hydroxide until the solution is just alkaline, then add 4 drops of ammonium hydroxide and 5 mL of ammonium oxalate TS: any turbidity produced within 15 minutes does not exceed that in a blank containing 0.1 mg of added Ca carried through the entire procedure (0.001%).

Phosphate (Reagent test)—Transfer 2 g to a beaker, and add 5 mL of hydrochloric acid and 2 g of potassium iodide. Heat the solution for 5 minutes, and cool. Add 2 mL of 30 percent hydrogen peroxide, and evaporate the solution to dryness. Rinse the walls of the beaker with a few mL of water, and add 2 mL of hydrochloric acid and 2 mL of 30 percent hydrogen peroxide. Evaporate again to dryness: the residue shows not more than 0.01 mg of PO_4 (5 ppm).

Sodium Iodate, NaIO_3 —**197.9** [7681-55-2]—White to yellowish-white powder. Use a suitable reagent grade.

Sodium Lauryl Sulfate—See *Sodium Dodecyl Sulfate*.

Sodium Metabisulfite, $\text{Na}_2\text{S}_2\text{O}_5$ —**190.11**

[7681-57-4]—Use ACS reagent grade.

Sodium Metaperiodate, NaIO_4 —**213.89**

[7790-28-5]—Use ACS reagent grade Sodium Periodate.

Sodium Methoxide, CH_3ONa —**54.02** [124-41-4]—

Fine, white powder. Reacts violently with water with evolution of heat. Soluble in alcohol and in methanol.

Assay—Transfer about 220 mg to a tared, glass-stoppered flask, and weigh accurately. Dissolve the test specimen in about 10 mL of methanol, then add 100 mL of water slowly, with stirring. Add phenolphthalein TS, and titrate with 0.1 N hydrochloric acid VS to a colorless endpoint: each mL of 0.1 N hydrochloric acid VS is equivalent to 5.402 mg of CH_3ONa . Not less than 98.0% is found.

Sodium Molybdate, $\text{Na}_2\text{MoO}_4 \cdot 2\text{H}_2\text{O}$ —**241.95**

[7631-95-0]—Use ACS reagent grade.

Sodium Nitrate, NaNO_3 —**84.99** [7631-99-4]—Use

ACS reagent grade.

Sodium Nitrite, NaNO_2 —**69.00** [7632-00-0]—Use ACS

reagent grade.

Sodium Nitroferricyanide (*Sodium Nitroprusside*), $\text{Na}_2\text{Fe}(\text{NO})(\text{CN})_5 \cdot 2\text{H}_2\text{O}$ —**297.95** [13755-38-9]—Use ACS reagent grade.

Sodium 1-Octanesulfonate—See *Octanesulfonic Acid Sodium Salt*.

Sodium Oxalate, $\text{Na}_2\text{C}_2\text{O}_4$ —**134.00** [62-76-0]—Use ACS reagent grade.

[NOTE—Sodium Oxalate of a quality suitable as a primary standard is available from the Office of Standard Reference Materials, National Institute of Standards and Technology, Washington, DC, www.nist.gov, as standard sample No. 40.]

Sodium (tri) Pentacyanoamino Ferrate [*Trisodium Aminepentacyanoferrate* (3-)], $\text{Na}_3[\text{Fe}(\text{CN})_5\text{NH}_3]$ —**271.93** [14099-05-9]—Yellow to tan powder. Soluble in water.

Solubility—Dissolve 500 mg in 50 mL of water, and allow to stand for 1 hour: the solution is clear and free from foreign matter.

Sensitivity—

1,1-DIMETHYLHYDRAZINE STANDARD SOLUTION—Place 500 mL of water in a 1-L volumetric flask, and add from a buret 1.27 mL of anhydrous 1,1-dimethylhydrazine. Dilute with water to volume, and mix. Pipet 10 mL of this solution into a 100-mL volumetric flask, and dilute with water to volume. Each mL of this solution contains the equivalent of 100 µg of 1,1-dimethylhydrazine.

BUFFER SOLUTION—Transfer 4.8 g of citric acid monohydrate to a 1-L volumetric flask, dissolve in water, add 14.6 g of sodium phosphate, swirl to dissolve, and dilute with water to volume.

TEST PREPARATION—Dissolve 100 mg of sodium (tri)pentacyanoamino ferrate in 100 mL of water.

PROCEDURE—Into each of five 25-mL volumetric flasks pipet 0 mL, 0.25 mL, 0.50 mL, 1.0 mL, and 1.5 mL, respectively, of 1,1-Dimethylhydrazine standard solution; to each

add 15 mL of *Buffer solution*, and swirl to mix. To each flask, add by pipet 2 mL of *Test preparation*, mix, dilute with *Buffer solution* to volume, and allow to stand for 1 hour. Using a suitable spectrophotometer, 1-cm cells, and the solution containing no 1,1-Dimethylhydrazine standard solution as the blank, determine the absorbances of the remaining solutions at 500 nm. Plot the observed absorbance as the ordinate versus the concentration of standard as the abscissa on coordinate paper, and draw the curve of best fit. The plot is linear and the absorbance of the 150- μ g solution is not less than 0.65.

Sodium 1-Pentanesulfonate (1-Pentanesulfonic Acid Sodium Salt), $C_5H_{11}NaO_3S \cdot H_2O$ —**192.21** [207605-40-1]—Use a suitable grade with a content of NLT 98.0%.

Sodium 1-Pentanesulfonate, Anhydrous (1-Pentanesulfonic Acid Sodium Salt, Anhydrous), $C_5H_{11}SO_3Na$ —**174.19** [22767-49-3]—Use a suitable grade with a content of NLT 98%.

Sodium Perchlorate, $NaClO_4 \cdot H_2O$ —**140.46** [7791-07-3]—Use ACS reagent grade.

Sodium Peroxide, Na_2O_2 —**77.98** [1313-60-6]—Use ACS reagent grade.

Sodium Phosphate, Dibasic (Disodium Phosphate; Disodium Hydrogen Phosphate; Sodium Phosphate, Dibasic, Heptahydrate), $Na_2HPO_4 \cdot 7H_2O$ —**268.07** [7782-85-6]—Use ACS reagent grade Sodium Phosphate, Dibasic, Heptahydrate.

Sodium Phosphate, Dibasic, Anhydrous (Anhydrous Disodium Hydrogen Phosphate) (for buffer solutions), Na_2HPO_4 —**141.96** [7558-79-4]—Use ACS reagent grade Sodium Phosphate, Dibasic, Anhydrous.

Sodium Phosphate, Dibasic, Dihydrate (Sodium Monohydrogen Phosphate; Disodium Hydrogen Phosphate), $Na_2HPO_4 \cdot 2H_2O$ —**177.99** [10028-24-7]—Use a suitable grade with a content of not less than 99.5%. [NOTE—A suitable grade is available from www.emdchemicals.com, catalog number SX0713.]

Sodium Phosphate Dibasic, Dodecahydrate (Disodium Hydrogen Phosphate, Dodecahydrate), $Na_2HPO_4 \cdot 12H_2O$ —**358.14** [10039-32-4]—Use a suitable grade with a content of between 98.0% and 102.0% of $Na_2HPO_4 \cdot 12H_2O$.

Sodium Phosphate, Dibasic, Heptahydrate (Disodium Hydrogen Phosphate Heptahydrate; Disodium Phosphate), $Na_2HPO_4 \cdot 7H_2O$ —**268.07** [7782-85-6]—Use ACS reagent grade.

Sodium Phosphate, Monobasic (Sodium Biphosphate; Sodium Dihydrogen Phosphate; Acid Sodium Phosphate; Monosodium Orthophosphate), $NaH_2PO_4 \cdot H_2O$ —**137.99** [10049-21-5]—Use ACS reagent grade.

Sodium Phosphate, Monobasic, Anhydrous (Sodium Biphosphate; Sodium Dihydrogen Phosphate; Acid Sodium Phosphate; Monosodium Orthophosphate), NaH_2PO_4 —**119.98** [7558-80-7]—Use a suitable grade with a content of not less than 99.0%.

Sodium Phosphate, Monobasic, Dihydrate (Sodium Dihydrogen Phosphate, Dihydrate), $NaH_2PO_4 \cdot 2H_2O$ —**156.01** [13472-35-0]—Use a suitable grade with a content of not less than 99.0%.

Sodium Phosphate, Tribasic, $Na_3PO_4 \cdot 12H_2O$ —**380.12** [10101-89-0]—Use ACS reagent grade.

Sodium Phosphite Pentahydrate (Disodium Hydrogen Phosphite), $Na_2HPO_3 \cdot 5H_2O$ —**216.04** [13517-23-2]—Use a suitable grade with a content of not less than 98%.

[NOTE—A suitable grade is available from Fluka, www.sigma-aldrich.com, catalog number 04283.]

Sodium Pyrophosphate, $Na_4P_2O_7 \cdot 10H_2O$ —**446.06** [13472-36-1]—Use ACS reagent grade.

Sodium Pyruvate, CH_3COCO_2Na —**110.04** [113-24-6]—White to practically white powder or crystalline solid. Soluble in water.

Assay—Transfer about 300 mg, accurately weighed, to a high-form titration beaker, add 150 mL of glacial acetic acid, and stir until dissolved. Titrate with 0.1 N perchloric acid VS, determining the endpoint potentiometrically, using a

glass electrode and a calomel electrode modified to use 0.1 N tetramethylammonium chloride in methanol as the electrolyte. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N perchloric acid is equivalent to 11.00 mg of CH_3COCO_2Na : not less than 98.0% is found.

Solubility—Dissolve 1.5 g in 25 mL of water: the solution is clear and complete.

Free acid—Dissolve 10 g in 150 mL of water, and titrate with 0.5 N sodium hydroxide VS, determining the endpoint potentiometrically: not more than 2.8 mL of 0.5 N sodium hydroxide is consumed (about 1% as $C_3H_4O_3$).

Sodium Salicylate [54-21-7]—It complies with the specifications under *Sodium Salicylate* (USP monograph), and in addition meets the requirements of the following test.

Nitrate—Dissolve 100 mg in 5 mL of water, and superimpose the solution upon 5 mL of sulfuric acid: no brownish-red color appears at the junction of the two liquids.

Sodium Selenite, Na_2SeO_3 —**172.94** [10102-18-8]—White, odorless, crystalline powder, usually partially hydrated. Freely soluble in water; insoluble in alcohol.

Assay—Accurately weigh about 180 mg, previously dried at 120° to constant weight, and dissolve it in 50 mL of water in a glass-stoppered flask. Add, successively, 3 g of potassium iodide and then 5 mL of hydrochloric acid, insert the stopper, and allow to stand for 10 minutes. Add 50 mL of water, 50.0 mL of 0.1 N sodium thiosulfate VS, and 3 mL of starch TS, and immediately titrate with 0.1 N iodine VS to a blue color. Perform a blank determination. The difference in volumes of 0.1 N iodine is equivalent to 4.323 mg of Na_2SeO_3 . Between 98% and 101% is found.

Solubility—One g in 10 mL of water shows not more than a faint haze.

Carbonate—To 500 mg add 1 mL of water and 2 mL of diluted hydrochloric acid: no effervescence is produced.

Chloride (Reagent test)—A 500-mg portion shows not more than 0.05 mg of Cl (0.01%).

Nitrate (Reagent test)—A 200-mg portion dissolved in 3 mL of water shows not more than 0.02 mg of NO_3 (0.01%).

Selenate and sulfate (as SO_4)—To 500 mg in a small evaporating dish add 20 mg of sodium carbonate and 10 mL of hydrochloric acid. Slowly evaporate the solution on a steam bath under a hood to dryness. Wash the sides of the dish with 5 mL of hydrochloric acid, and again evaporate to dryness. Dissolve the residue in a mixture of 15 mL of hot water and 1 mL of hydrochloric acid. Proceed as directed under *Sulfate in Reagents* (Reagent test, *Method I*), beginning with "Filter the solution." The test specimen shows no more turbidity than that produced by 0.15 mg of SO_4 (0.03%).

Sodium Sulfate (Glauber's Salt), $Na_2SO_4 \cdot 10H_2O$ —**322.20** [7727-73-3]—Use ACS reagent grade.

Sodium Sulfate, Anhydrous, Na_2SO_4 —**142.04** [7757-82-6]—Use ACS reagent grade.

For use in assaying alkaloids by gas-liquid chromatography, it conforms to the following additional test.

Suitability for alkaloid assays—Transfer about 10 mg of atropine, accurately weighed, to a 25-mL volumetric flask, dissolve in and dilute with alcohol to volume. Pipet 3 mL of the solution into each of two 60-mL separators, and add to each 10 mL of water, 1 mL of 1 N sodium hydroxide, and 10 mL of chloroform. Shake thoroughly, and allow the layers to separate. Filter the organic phase from one separator through phase-separating paper, previously washed with 5 mL of chloroform, supported in a funnel, and collect the filtrate in a suitable container. Add 10 mL of chloroform to the separator, shake thoroughly, and filter the organic layer through the same phase-separating paper, collecting and combining the filtrates in the same container. Designate the combined filtrates as *Solution A*. Filter the organic phase from the second separator through 30 g of the Anhydrous

Sodium Sulfate, supported on a pledget of glass wool in a small funnel, and previously washed with chloroform, and collect the filtrate in a suitable container. Add 10 mL of chloroform to the separator, shake thoroughly, and filter the organic layer through the same portion of anhydrous sodium sulfate, collecting and combining the two filtrates in the same container. Designate the combined filtrates as *Solution B*. Evaporate the two solutions in vacuum to a volume of about 1 mL. Inject an accurately measured volume of *Solution A* into a suitable gas chromatograph, and record the peak height. Repeat the determination with a second accurately measured volume of *Solution A*, record the peak height, and obtain the average of the two results. In a similar manner, determine the peak height of two portions of *Solution B*, and obtain the average of the results. The average value obtained for *Solution B* is within 5.0% of the value obtained for *Solution A*.

Under typical conditions, the gas chromatograph contains a 4-mm \times 1.2-m glass column packed with 3% phase G3 on packing S1A. After curing and conditioning, the column temperature is maintained at 210°, the injector port temperature at 225°, and the detector block temperature at 240° during the determinations. The carrier gas is helium, flowing at a rate of 60 mL per minute.

Sodium Sulfate Decahydrate—Use *Sodium Sulfate*.

Sodium Sulfide, $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$ —**240.18** [1313-84-4]—Use ACS reagent grade.

Sodium Sulfite—Use *Sodium Sulfite, Anhydrous*.

Sodium Sulfite, Anhydrous (*Exsiccated Sodium Sulfite*), Na_2SO_3 —**126.04** [7753-83-7]—Use ACS reagent grade.

Sodium p-Sulfophenylazochromotrope [*Trisodium Salt of 4,5-Dihydroxy-3-(p-sulfophenylazo)-2,7-naphthalenedisulfonic Acid*], $\text{C}_{16}\text{H}_9\text{N}_2\text{Na}_3\text{O}_{11}\text{S}_3 \cdot 3\text{H}_2\text{O}$ —**624.47**—Bright red powder. Very soluble in water; insoluble in alcohol. Combines with zirconium oxychloride to form a soluble pink zirconium lake.

[NOTE—The reagent is available as Catalog No. 7309 from Distillation Products Industries, Eastman Organic Chemicals Dept., Rochester, NY 14650. A procedure for its preparation is described in *Z. Anal. Chem.*, 146, 417 (1955).]

Sodium Tartrate, $\text{Na}_2\text{C}_4\text{H}_4\text{O}_6 \cdot 2\text{H}_2\text{O}$ —**230.08** [6106-24-7]—Use ACS reagent grade.

Sodium Tetraphenylborate, $\text{NaB}(\text{C}_6\text{H}_5)_4$ —**342.22** [143-66-8]—Use ACS reagent grade.

Sodium Tetraphenylboron—See *Sodium Tetraphenylborate*.

Sodium Thioglycolate (*Sodium Thioglycollate*), $\text{HSCH}_2\text{COONa}$ —**114.10** [367-51-1]—A white, crystalline powder. Very soluble in water; slightly soluble in alcohol. Is hygroscopic, and oxidizes in air. Store in tight, light-resistant containers. It should not be used if it is pale yellow or darker in color.

Assay—Accurately weigh about 250 mg, and dissolve in 50 mL of oxygen-free water. Add 5 mL of diluted hydrochloric acid, boil for 2 minutes, cool, and titrate the solution with 0.1 N iodine VS, adding 3 mL of starch TS toward the end: each mL of 0.1 N iodine is equivalent to 11.41 mg of $\text{HSCH}_2\text{COONa}$. Not less than 75% is found.

Insoluble matter—A solution of 1 g in 10 mL of water is clear, and practically complete.

Sulfide—Dissolve 500 mg in 10 mL of water in a small flask, add 2 mL of hydrochloric acid, then place a strip of filter paper, moistened with lead acetate TS, over the mouth of the flask, and bring the solution to a boil: the lead acetate paper is not darkened.

Sodium Thiosulfate, $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ —**248.19** [10102-17-7]—Use ACS reagent grade.

Sodium L-Thyroxine—Use *Levothyroxine Sodium* (USP monograph).

Sodium 3-(trimethylsilyl)-1-propane sulfonate (*Sodium 2,2-dimethyl-2-silapentane-5-sulfonate*), $\text{C}_6\text{H}_{15}\text{SiNaO}_3\text{S}$ —**218.32**—Use a suitable grade.

Sodium Tungstate, $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$ —**329.85** [10213-10-2]—Use ACS reagent grade.

Soluble Starch—See *Starch, Soluble*.

Solvent Hexane—See *Hexane, Solvent*.

Sorbitol—Use *Sorbitol* (NF monograph).

Stachyose Hydrate, $\text{C}_{24}\text{H}_{42}\text{O}_{21} \cdot x\text{H}_2\text{O}$ —**666.58** [10094-58-3]—Use a suitable grade.

Standard Sand, 20- to 30-Mesh—See *Sand, Standard 20- to 30-mesh*.

Stannous Chloride, $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$ —**225.65** [10025-69-1]—Use ACS reagent grade.

Starch, Potato—The starch separated from the tubers of *Solanum tuberosum* Linné (Fam. Solanaceae). A more or less finely granular powder, consisting of starch grains of characteristic shape and appearance when examined microscopically.

Starch, Soluble (*for iodimetry*) [9005-84-9]—Use ACS reagent grade.

Starch, Soluble, Purified—White, amorphous powder; under microscopic examination it shows the characteristic form of potato starch. Soluble in hot water; very slightly soluble in alcohol.

TEST SOLUTION FOR DETERMINATION OF PH AND SENSITIVITY—Stir 2.0 g in 10 mL of water, add boiling water to make 100 mL, and boil for 2 minutes. The hot solution is almost clear. On cooling, the solution may become opalescent or turbid, but does not gel. Use it as the *Test solution*.

pH (791)—The pH of the *Test solution* is between 6.0 and 7.5.

Sensitivity—Mix 2.5 mL of *Test solution*, 97.5 mL of water, and 0.50 mL of 0.010 N iodine: a distinct blue color results, and it disappears upon the addition of 0.50 mL of 0.010 N sodium thiosulfate.

Absorbance—Prepare a pH 5.3 buffer solution by dissolving 43.5 g of sodium acetate (trihydrate) and 4.5 mL of glacial acetic acid in water, transferring the resultant solution to a 250-mL volumetric flask, adding water to volume, and mixing.

Dissolve 1.00 g of Soluble Purified Starch in 2.5 mL of the buffer solution by warming, transfer to a 100-mL volumetric flask, add water to volume, and mix. Add 0.50 mL of this solution to a 100-mL volumetric flask containing about 75 mL of water, 1 mL of 1 N hydrochloric acid, and 1.5 mL of 0.020 N iodine, swirling the flask during the addition. Add water to volume, mix, and allow to stand in the dark for 1 hour. The absorbance of this solution, measured at 575 nm in a 1-cm cell against a blank, is between 0.5 and 0.6.

Reducing substances—Shake 10.0 g with 100 mL of water for 15 minutes, and allow to settle for about 12 hours. Filter a portion of the supernatant through fine sintered glass. To 50 mL of the filtrate add 50 mL of alkaline cupric tartrate TS, and boil for 1 to 2 minutes. Filter the resulting cuprous oxide, wash it with hot water and then with alcohol, and dry it at 105° for 2 hours: not more than 47 mg is found, corresponding to 0.7% of reducing sugars as maltose.

Loss on drying (731)—Dry it at 105° for 2 hours: it loses not more than 10% of its weight.

Residue on ignition (281): not more than 0.5%.

Stearic Acid, $\text{C}_{18}\text{H}_{36}\text{O}_2$ —**284.48** [57-11-4]—Hard, white crystals or amorphous, white powder. Freely soluble in chloroform and in ether; soluble in alcohol and in solvent hexane.

Congealing temperature (651): between 67° and 69°.

Acid value (401): between 196 and 199.

Iodine value (401): not more than 1.

Saponification value (401): between 197 and 200.

Palmitic acid—Determine as directed in the Assay under *Stearic Acid* (NF monograph): not more than 5.0% is found.

Stearyl Alcohol (1-Octadecanol), $C_{18}H_{38}O$ —**270.49** [112-92-5]—White flakes, granules, or crystals. Soluble in alcohol, in ether, in acetone, and in benzene; insoluble in water.

Melting range (741): between 56° and 58°.

Other requirements—It conforms to the tests for *Acid value*, *Iodine value*, and *Hydroxyl value* under *Stearyl Alcohol* (NF monograph).

Stronger Ammonia Water—See *Ammonia Water*, *Stronger*.

Strontium Acetate, $Sr(CH_3COO)_2 \cdot \frac{1}{2}H_2O$ —**214.72** [543-94-2]—White, crystalline powder. Soluble in 3 parts of water; slightly soluble in alcohol.

Assay—Ignite about 3 g, accurately weighed, in a platinum crucible, protecting from sulfur in the flame. Cool, transfer the crucible with the residue to a beaker, and add 50 mL of water and 40.0 mL of 1 N hydrochloric acid VS. Boil gently for 30 minutes or longer, if necessary; filter; wash with hot water until the washings are neutral; add methyl red TS; and titrate the excess acid with 1 N sodium hydroxide VS. Each mL of 1 N hydrochloric acid is equivalent to 107.4 mg of $Sr(CH_3COO)_2 \cdot \frac{1}{2}H_2O$: not less than 99% is found.

Insoluble matter (Reagent test): not more than 2 mg, from 10 g (0.02%).

Free alkali or free acid—Dissolve 3 g in 30 mL of water, and add 3 drops of phenolphthalein TS: no pink color is produced. Titrate with 0.1 N sodium hydroxide VS to a pink color: not more than 0.30 mL of the 0.1 N sodium hydroxide is required.

Barium—Dissolve 1 g in 10 mL of water, and add 1 drop of glacial acetic acid and 5 drops of potassium dichromate solution (1 in 10): no turbidity is produced within 2 minutes (about 0.02%).

Calcium—Ignite 1 g until completely carbonized. Warm the residue with a mixture of 3 mL of nitric acid and 10 mL of water, filter, wash with 5 mL of water, and evaporate the filtrate on a steam bath to dryness. Powder the residue, and dry it at 120° for 3 hours. Reflux the dried powder with 15 mL of dehydrated alcohol for 10 minutes, cool in ice, and filter. Repeat the extraction with 10 mL of dehydrated alcohol. Evaporate the combined filtrates to dryness, add 0.5 mL of sulfuric acid, and ignite: the weight of the residue is not more than 10 mg (0.3% of Ca).

Chloride (Reagent test)—One g shows not more than 0.1 mg of Cl (0.01%).

Heavy metals (Reagent test): 0.001%.

Iron (241)—Dissolve 1.0 g in 45 mL of water, and add 2 mL of hydrochloric acid: the solution shows not more than 0.01 mg of Fe (0.001%).

Alkali salts—Dissolve 2 g in 80 mL of water, heat to boiling, add an excess of ammonium carbonate TS, boil for 5 minutes, dilute with water to 100 mL, and filter. Evaporate 50 mL of the filtrate, and ignite: the residue, after correcting for the ignition residue from half the volume of the clear ammonium carbonate TS used above, is not more than 3 mg (0.3%).

Nitrate—Dissolve 1 g in 10 mL of water, add 0.10 mL of indigo carmine TS, and then add 10 mL of sulfuric acid: the blue color persists for 5 minutes (about 0.01% of NO_3).

Strontium Hydroxide (*Strontium Hydroxide Octahydrate*), $Sr(OH)_2 \cdot 8H_2O$ —**265.76** [18480-07-4]—White, crystalline, free-flowing powder. Sparingly soluble in water. May absorb carbon dioxide from the air. Keep tightly closed.

Assay and carbonate—Accurately weigh about 5 g, dissolve in 200 mL of warm carbon dioxide-free water in a glass-stoppered, 500-mL flask, add phenolphthalein TS, and titrate with 1 N hydrochloric acid VS to determine the hydroxide alkalinity. Then add methyl orange TS, and titrate with 1 N hydrochloric acid VS. Each mL of 1 N hydrochloric acid required to reach the phenolphthalein endpoint is equivalent to 132.9 mg of $Sr(OH)_2 \cdot 8H_2O$, and each additional mL of 1 N hydrochloric acid VS required to reach the methyl orange endpoint is equivalent to 73.8 mg of $SrCO_3$. Not less than 95.0% of $Sr(OH)_2 \cdot 8H_2O$ and not more than 3.0% of $SrCO_3$ are found.

Chloride (Reagent test)—Dissolve 1.0 g in 100 mL of water, and filter if necessary: 1.0 mL of the solution shows not more than 0.01 mg of Cl (0.1%).

Calcium (Reagent test)—

TEST SOLUTION—Dissolve 5.0 g in water, and dilute with water to 100 mL.

SAMPLE SOLUTION—Dilute 10.0 mL of the *Test solution* with water to 100 mL.

CONTROL SOLUTION—To 10.0 mL of the *Test solution* add 0.50 mg of calcium ion (Ca), and dilute with water to 100 mL.

PROCEDURE—Determine the background emission at 416.7 nm: the limit is 0.1%.

Iron—Dissolve 1 g in warm water, and dilute with water to 100 mL. To 20 mL of this solution add 2 mL of hydrochloric acid and 0.1 mL of 0.1 N potassium permanganate, allow to stand for 5 minutes, and add 3 mL of ammonium thiocyanate solution (3 in 10). Any red color produced is not darker than that of a control containing 0.03 mg of added Fe (0.015%).

Heavy metals—Dissolve 2.0 g in 14 mL of dilute hydrochloric acid (1 in 6), and evaporate on a steam bath to dryness. Take up the residue in 25 mL of water, filter, and dilute with water to 100 mL (*Test solution*). To 5.0 mL of the *Test solution* add 0.02 mg of lead (Pb), and dilute with water to 30 mL, to provide the standard. For the test specimen, use 30 mL of the *Test solution*. Adjust each solution with diluted acetic acid or ammonia TS to a pH between 3.0 and 4.0 (using short-range pH paper), dilute with water to 40 mL, and add 10 mL of freshly prepared hydrogen sulfide TS: any brown color developed in the sample solution is not darker than that in the control solution (0.004%).

Strychnine Sulfate, $(C_{21}H_{22}N_2O_2)_2 \cdot H_2SO_4 \cdot 5H_2O$ —**856.98** [60-41-3]—Colorless or white crystals, or a white, crystalline powder. Its solutions are levorotatory. One g dissolves in about 35 parts of water, in 85 mL of alcohol, and in about 220 mL of chloroform. Insoluble in ether.

Solubility—A solution of 500 mg in 25 mL of water is complete, clear, and colorless.

Residue on ignition (Reagent test): not more than 0.1%.

Brucine—To 100 mg add 1 mL of dilute nitric acid (1 in 2): a yellow color may be observed, but not a red or reddish-brown color.

Styrene-Divinylbenzene Anion-exchange Resin, 50- to 100-Mesh—See *Anion-exchange Resin, 50- to 100-Mesh*, *Styrene-Divinylbenzene*.

Styrene-Divinylbenzene Cation-exchange Resin, Strongly Acidic—See *Cation-exchange Resin, Styrene-Divinylbenzene, Strongly Acidic*.

Styrene-Divinylbenzene Copolymer Beads—Neutral, porous, cross-linked beads, 200–400 mesh, molecular weight operating range up to 2,000 (based on beads fully swollen in benzene). Suitable for use in the gel permeation separation of lipophilic polymers and other solutes requiring organic eluant.

[NOTE—A suitable grade is available commercially as “BioBeads S-X” from Bio-Rad, www.bio-rad.com.]

Succinic Acid, $C_4H_6O_4$ —**118.09** [771-50-6]—Use ACS reagent grade.

Sudan III, $C_{22}H_{16}N_4O$ —**352.39** [85-86-9]—Red to red-brown powder. Use a suitable grade.

Assay—When tested by thin-layer chromatography (see *Chromatography* (621)) with the use of plates coated with chromatographic silica gel mixture and a developing system consisting of a mixture of hexane and ethyl acetate (80:20), and examined under short-wavelength UV light, a single spot is exhibited, with trace impurities.

Sudan IV, $C_{24}H_{20}N_4O$ —**380.44** [85-83-6]—Brown to reddish-brown powder.

Assay—Transfer about 25 mg, accurately weighed, to a 100-mL volumetric flask. Dissolve in chloroform, dilute with chloroform to volume, and mix. Dilute 2.0 mL of the resulting solution with chloroform to 50.0 mL. Determine the absorbance of this solution in 1-cm cells at the wavelength of maximum absorbance at about 520 nm, with a suitable spectrophotometer, using chloroform as the blank. Calculate the percentage of Sudan IV in the test specimen taken by the formula:

$$(100A)/(85C)$$

in which A is the absorbance at 520 nm and C is the concentration of the test specimen in g per L. Not less than 90% is found.

Loss on drying (731)—Dry it at 105° for 2 hours: it loses not more than 10% of its weight.

Sulfamerazine (4-Amino-N-(4-methyl-2-pyrimidinyl)-benzenesulfonamide), $C_{11}H_{12}N_4O_2S$ —**264.30** [127-79-7]—Use a suitable grade with a content of NLT 99.0%.

Sulfamic Acid, HSO_3NH_2 —**97.09** [5329-14-6]—Use ACS reagent grade.

Sulfanilamide, $C_6H_8N_2O_2S$ —**172.21** [63-74-1]—Use USP Sulfanilamide Melting Point RS.

Sulfanilic Acid, $p\text{-NH}_2C_6H_4SO_3H \cdot H_2O$ —**191.21** [121-57-3]—Use ACS reagent grade.

Sulfatase Enzyme Preparation—Use a suitable grade.

[NOTE—A suitable grade is available commercially under catalog number S-9626 from Sigma-Aldrich, Web site: www.sigma-aldrich.com.]

Sulfathiazole Sodium (4-Amino-N-2-thiazolylbenzenesulfonamide Sodium Salt), $C_9H_8N_3NaO_2S_2$ —**277.29** [144-74-1]—Use a suitable grade.

Sulfonic Acid Cation-exchange Resin—See *Cation-exchange Resin, Sulfonic Acid*.

Sulfosalicylic Acid, $C_6H_3(COOH)(OH)(SO_3H) \cdot 1,2,5 \cdot 2H_2O$ —**254.22** [97-05-2]—Use ACS reagent grade.

Sulfur—Use *Precipitated Sulfur* (USP monograph).

Sulfur Dioxide Detector Tube—A fuse-sealed glass tube so designed that gas may be passed through it and containing suitable absorbing filters and support media for an iodine-starch indicator.

Measuring range: 1 to 25 ppm.

[NOTE—Available from Draeger Safety, Inc., www.draeger.com, or from Gastec Corp., www.gastec.co.jp, distributed in the USA by www.nextteq.com.]

Sulfuric Acid, H_2SO_4 —**98.08** [7664-93-9]—Use ACS reagent grade.

Sulfuric Acid, Diluted (10 percent)—Cautiously add 57 mL of sulfuric acid to about 100 mL of water, cool to room temperature, and dilute with water to 1000 mL.

Sulfuric Acid, Fluorometric—Use ACS reagent grade Sulfuric Acid that conforms to the following additional test:

Fluorescence—Using a suitable fluorometer having a sharp cut-off 360-nm excitation filter and a sharp cut-off 415-nm excitation filter, determine the fluorescence of the sulfuric acid in a cuvette previously rinsed with water followed by several portions of the acid under examination: the fluores-

cence does not exceed that of quinine sulfate solution (1 in 1,600,000,000), similarly measured.

Sulfuric Acid, Fuming, H_2SO_4 plus free SO_3 [8014-95-7]—having a nominal content of 15%, 20%, or 30% of free SO_3 —Use ACS reagent grade (containing between 15.0% and 18.0%, between 20.0% and 23.0%, or between 30.0% and 33.0% of free SO_3).

Sulfuric Acid, Nitrogen Free, H_2SO_4 —**98.08** [7664-93-9]—Use a suitable grade.

[NOTE—A suitable grade is available as Sulfuric Acid, Ultrex II, catalog number 6902-05 from www.mallbaker.com.]

Sulfurous Acid, H_2SO_3 —**82.08** [7782-99-2]—A water solution of sulfur dioxide. Use ACS reagent grade.

Sunflower Oil [8001-21-6]—Use a suitable grade.

Supports for Gas Chromatography—See supports for gas chromatography in the *Chromatographic Reagents* section under *Chromatography* (621).

Tannic Acid (Tannin) [1401-55-4]—Use ACS reagent grade.

Tartaric Acid, $H_2C_4H_4O_6$ —**150.09**—Use ACS reagent grade.

Tertiary Butyl Alcohol—See *Butyl Alcohol, Tertiary*.

Testosterone Benzoate, $C_{26}H_{32}O_2$ —**376.53**—Use a suitable grade.

2',4',5',7'-Tetrabromofluorescein (Eosin Y, Eosin Yellowish, Eosin Bromo ES, Solvent Red 43, Acid Red 87), $C_{20}H_8Br_4O_5$ —**167.8** [630-20-6]—Dark red to brown powder. Solubility 0.1% in water (clear orange solution). Use a suitable grade.

Tetrabromophenolphthalein Ethyl Ester, $C_{22}H_{14}Br_4O_4$ —**661.96**—Use ACS reagent grade.

Tetrabutylammonium Bromide, $(C_4H_9)_4NBr$ —**322.37** [1643-19-2]—Use ACS reagent grade.

Tetrabutylammonium Hydrogen Sulfate, $C_{16}H_{37}NO_4S$ —**339.54** [32503-27-8]—White, crystalline powder. Soluble in alcohol yielding a slightly hazy, colorless solution.

Assay—Dissolve about 170 mg, accurately weighed, in 40 mL of water. Titrate with 0.1 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination and make any necessary correction. Each mL of 0.1 N sodium hydroxide is equivalent to 33.95 mg of $C_{16}H_{37}NO_4S$. Not less than 97.0% is found.

Melting range (741): between 169° and 173°.

Tetrabutylammonium Hydrogen Sulfate Ion Pairing Reagent—A mixture of tetrabutylammonium hydrogen sulfate and phosphate buffer. Use a suitable grade.

[NOTE—A suitable grade is available as catalog number WAT084189 from the Waters Corporation (www.waters.com).]

0.4 M Aqueous Tetrabutylammonium Hydroxide, $C_{16}H_{37}NO$ —**259.47** [2052-49-5]—Use a suitable grade.

[NOTE—A suitable grade is available as catalog number 420120025 from www.fishersci.com.]

Tetrabutylammonium Hydroxide, 1.0 M in Methanol [2052-49-5]—Use a suitable grade.

Tetrabutylammonium Hydroxide 30-Hydrate, $C_{16}H_{37}NO \cdot 30H_2O$ —**799.93** [2052-49-5]—Use a suitable grade with a content of not less than 98.0%.

Tetrabutylammonium Hydroxide, 40 Percent in Water, $[CH_3(CH_2)_3]_4NOH$ —**259.47** [2052-49-5]—Use a suitable grade.

Tetrabutylammonium Iodide, $(C_4H_9)_4NI$ —**369.37** [311-28-4]—White, shiny, crystalline flakes. Soluble in alcohol and in ether; slightly soluble in water.

Assay—Dissolve 370 mg, accurately weighed, in 60 mL of acetone with vigorous stirring. Stir the solution by mechanical means, add 10 mL of 16% sulfuric acid, and titrate with 0.1 N silver nitrate VS, determining the endpoint potentiometrically, using a glass-silver electrode system, and adding the titrant in 0.1-mL increments as the endpoint is approached. Perform a blank determination, and make any necessary corrections. Each mL of 0.1 N silver nitrate is

equivalent to 36.94 mg of $(C_4H_9)_4NI$: not less than 99.0% is found.

Tetrabutylammonium Phosphate, $(C_4H_9)_4NH_2PO_4$ —**339.46** [5574-97-0]—White to off-white powder. Soluble in water.

Assay—Dissolve about 1.5 g, accurately weighed, in 100 mL of water. Without delay, titrate with 0.5 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.5 N sodium hydroxide is equivalent to 169.7 mg of $(C_4H_9)_4NH_2PO_4$. Not less than 97.0% is found.

2,3,7,8-Tetrachlorodibenzo-*p*-dioxin, ^{13}C -labeled, $^{13}C_{12}H_4Cl_4O_2$ —**333.84**—Clear, colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with an electron-capture detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 300°; the detector temperature is maintained at 300°; and the column temperature is maintained at 70° and programmed to rise 15° per minute to 300°. The area of the $^{13}C_{12}H_4Cl_4O_2$ peak is not less than 99.0% of the total peak area.

[NOTE—A suitable grade is available from Cambridge Isotopes Laboratories (www.isotope.com).]

2,3,7,8-Tetrachlorodibenzofuran, ^{13}C -labeled, $^{13}C_{12}H_4Cl_4O$ —**317.84**—Clear, colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with an electron-capture detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.32-mm \times 60-m capillary column coated with a 1- μ m layer of phase G27; the injection port temperature is maintained at 300°; the detector temperature is maintained at 350°; and the column temperature is maintained at 70° and programmed to rise 15° per minute to 275°. The area of the $^{13}C_{12}H_4Cl_4O$ peak is not less than 99.0% of the total peak area.

[NOTE—A suitable grade is available from Cambridge Isotopes Laboratories (www.isotope.com).]

1,1,2,2-Tetrachloroethane, $C_2H_2Cl_4$ —**167.8** [630-20-6]—Colorless clear liquid. Specific gravity: 1.553. Refractive index at 20° is 1.481. Use a suitable grade.

Tetracosane, $C_{24}H_{50}$ —**338.66** [646-31-1]—White powder.

Melting range (741): between 51° and 53°.

Tetradecane, $C_{14}H_{30}$ —**198.39** [629-59-4]—Clear, colorless liquid.

Assay—When examined by gas-liquid chromatography, it shows a purity of not less than 98%. The following conditions have been found suitable for assaying the reagent: a 3-mm \times 2.4-m stainless steel column packed with phase G16 on support S1; the carrier gas is helium, flowing at a rate of 27.5 mL per minute; the column temperature is maintained at 250°, the injection port is maintained at 200°, and the detector is maintained at 280°. A flame-ionization detector is employed.

Melting range, Class II (741): between 4° and 8°, within a 2° range.

Refractive index (831): between 1.4280 and 1.4300 at 20°.

Tetraethylammonium Perchlorate, $(C_2H_5)_4NClO_4$ —**229.70**—White crystals. Soluble in water. Use a suitable grade.

Tetraethylene Glycol, $C_8H_{18}O_5$ —**194.23** [112-60-7]—Nearly colorless liquid. Refractive index: about 1.46.

Assay—When examined by gas-liquid chromatography, using suitable gas chromatographic apparatus and conditions, it shows a purity of not less than 90%.

Boiling range (Reagent test): between 177° and 187°, at a pressure of 9 mm of Hg.

Tetraethylenepentamine, $C_8H_{23}N_5$ —**189.31** [112-57-2]—Colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 250°; the detector temperature is maintained at 300°; and the column temperature is maintained at 150° and programmed to rise 10° per minute to 280°. The area of the $C_8H_{23}N_5$ peak is not less than 30% of the total peak area.

Refractive index (831): between 1.503 and 1.507 at 20°.

Tetraheptylammonium Bromide, $(C_7H_{15})_4NBr$ —**490.70** [4368-51-8]—White, flaky powder.

Melting range (741): between 89° and 91°.

Tetrahexylammonium Hydrogen Sulfate, $C_{24}H_{53}NO_4S$ —**451.75** [32503-34-7]—Use a suitable grade with a content of not less than 98.0%.

Delta-8-tetrahydrocannabinol (Δ -8-Tetrahydrocannabinol), $C_{21}H_{30}O_2$ —**314.47** [5957-75-5]—Use a suitable grade which may be a solid material or a solution in methanol. [NOTE—A suitable grade of a methanolic solution (1 mg/mL) is available from www.cerilliant.com, catalog number T-032.]

Tetrahydrofuran, C_4H_8O —**72.11** [109-99-9]—Use ACS reagent grade.

Tetrahydrofuran, Peroxide-Free, C_4H_8O —**72.11**—Use ACS reagent grade.

Peroxide—Transfer 8 mL of potassium iodide and starch TS to a 12-mL ground glass-stoppered cylinder about 15 mm in diameter. Fill completely with the substance under test, mix, and allow to stand protected from light for 5 minutes. No color develops.

Tetrahydrofuran, Stabilizer-Free—Use a suitable grade.

Tetrahydro-2-furancarboxylic Acid (\pm Tetrahydro-2-furoic Acid), $C_5H_8O_3$ —**116.12** [16874-33-2]—Use a suitable grade with a content of not less than 97%. [NOTE—A suitable grade is available from www.sigma-aldrich.com, catalog number 341517.]

N-(2-Tetrahydrofuroyl)piperazine (1-[(2-Tetrahydro-2-furanyl)carbonyl]piperazine), $C_9H_{16}N_2O_2$ —**184.23**—Use a suitable grade.

[NOTE—A suitable grade can be obtained from EMS-DÖTTIKON, www.ems-dottikon.ch.]

1,2,3,4-Tetrahydronaphthalene, $C_{10}H_{12}$ —**132.21** [119-64-2]—Colorless liquid.

Refractive index (831): 1.5401 at 20°.

Tetramethylammonium Bromide, $(CH_3)_4NBr$ —**154.05** [64-20-0]—Use ACS reagent grade.

Tetramethylammonium Chloride, $(CH_3)_4NCl$ —**109.60** [75-57-0]—Colorless crystals. Soluble in water and in alcohol; insoluble in chloroform.

Assay—Transfer about 200 mg, accurately weighed, to a beaker, add 50 mL of water and 10 mL of diluted nitric acid, swirl to dissolve the test specimen, add 50.0 mL of 0.1 N silver nitrate VS, and mix. Add 2 mL of ferric ammonium sulfate TS and 5 mL of nitrobenzene, shake, and titrate the excess silver nitrate with 0.1 N ammonium thiocyanate VS: each mL of 0.1 N silver nitrate is equivalent to 10.96 mg of $(CH_3)_4NCl$. Not less than 98% is found.

Tetramethylammonium Hydroxide, $(CH_3)_4NOH$ —**91.15** [75-59-2]—Available as an approximately 10% or approximately 25% aqueous solution, or as the crystalline pentahydrate. Is clear and colorless. Tetramethylammonium hydroxide is a stronger base than ammonia and rapidly absorbs carbon dioxide from the air. Store in tight containers.

Assay—Accurately weigh a glass-stoppered flask containing about 15 mL of water. Add a quantity of a solution of tetramethylammonium hydroxide, equivalent to about

200 mg of $(\text{CH}_3)_4\text{NOH}$, and again weigh. Add methyl red TS, and titrate the solution with 0.1 N hydrochloric acid VS: each mL of 0.1 N hydrochloric acid is equivalent to 9.115 mg of $(\text{CH}_3)_4\text{NOH}$.

Residue on evaporation—Evaporate 5 mL of solution on a steam bath, and dry at 105° for 1 hour: the weight of the residue is equivalent to not more than 0.02% of the weight of the test specimen.

Ammonia and other amines—Accurately weigh a quantity of solution, corresponding to about 300 mg of $(\text{CH}_3)_4\text{NOH}$, in a low-form weighing bottle tared with 5 mL of water. Add a slight excess of 1 N hydrochloric acid (about 4 mL), evaporate on a steam bath to dryness, and dry at 105° for 2 hours: the weight of the tetramethylammonium chloride so obtained, multiplied by 0.8317, represents the quantity, in mg, of $(\text{CH}_3)_4\text{NOH}$ in the portion of test specimen taken and corresponds to within 0.2% above or below that found in the Assay.

Tetramethylammonium Hydroxide, Pentahydrate, $(\text{CH}_3)_4\text{NOH} \cdot 5\text{H}_2\text{O}$ —**181.23** [10424-65-4]—White to off-white crystals. Is hygroscopic. Strong base. Keep well-closed. Soluble in water and in methanol.

Assay—Accurately weigh about 800 mg, dissolve in 100 mL of water, and titrate with 0.1 N hydrochloric acid VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N hydrochloric acid is equivalent to 18.22 mg of $(\text{CH}_3)_4\text{NOH} \cdot 5\text{H}_2\text{O}$: not less than 98% is found.

Tetramethylammonium Hydroxide Solution in Methanol [75-59-2]—A solution in methanol of tetramethylammonium hydroxide [$(\text{CH}_3)_4\text{NOH}$ —91.15]. Is generally available in concentrations of 10% and 25%. The following specifications apply specifically to the 25% concentration; for other concentrations, appropriate adjustments in the procedures may be necessary.

Assay—Accurately weigh about 1 g of the solution, and dilute with water to about 50 mL. Add phenolphthalein TS, and titrate with 0.1 N hydrochloric acid VS to the disappearance of the pink color: each mL of 0.1 N hydrochloric acid VS is equivalent to 91.15 mg of $(\text{CH}_3)_4\text{NOH}$. Between 23% and 25% is found.

Clarity—A portion of it in a test tube is clear, or only slightly turbid, when viewed transversely.

Tetramethylammonium Nitrate, $(\text{CH}_3)_4\text{NNO}_3$ —**136.15** [1941-24-8]—White crystals. Freely soluble in water.

Tetramethylbenzidine, (4-(4-Amino-3,5-dimethylphenyl)-2,6-dimethylaniline; 3,3',5,5'-Tetramethylbenzidine; 3,3',5,5'-Tetramethyl-[1,1'-biphenyl] 4,4'-diamine) $\text{C}_{16}\text{H}_{20}\text{N}_2$ —**240.34** [54827-17-7]—Use a suitable grade.

4,4'-Tetramethyldiaminodiphenylmethane [(4,4'-Methylenebis(N,N-dimethylaniline)], $[(\text{CH}_3)_2\text{NC}_6\text{H}_4]_2\text{CH}_2$ —**254.38** [101-61-1]—Off-white crystals.

Melting range (741): between 87° and 90° .

Tetramethylsilane, $(\text{CH}_3)_4\text{Si}$ —**88.23** [75-76-3]—Use ACS reagent grade.

Tetrapropylammonium Chloride, $\text{C}_{12}\text{H}_{28}\text{ClN}$ —**221.82** [5810-42-4]—Use a suitable grade with a content of not less than 98.0%.

Tetrasodium Ethylenediaminetetraacetate ((Ethylenedinitrilo)tetraacetic Acid Tetrasodium Salt), $\text{C}_{10}\text{H}_{12}\text{N}_2\text{Na}_4\text{O}_8$ —**380.17**—Fine, white, crystalline powder. Soluble in water.

Loss on drying (731)—Dry it at 105° for 4 hours: it loses not more than 8% of its weight.

Thallous Chloride, TlCl —**239.84**—Fine, white, crystalline powder. Soluble in about 260 parts of cold water and in about 70 parts of boiling water; insoluble in alcohol. *Poisonous; use with adequate ventilation.*

Assay—Dissolve about 500 mg, accurately weighed, in a mixture of 80 mL of water and 0.5 mL of sulfuric acid. When dissolution is complete, add 20 mL of hydrochloric

acid. Heat to 60° and maintain this temperature while titrating with 0.1 N ceric sulfate VS, determining the endpoint potentiometrically, using silver-silver chloride and platinum electrodes. Each mL of 0.1 N ceric sulfate is equivalent to 11.99 mg of TlCl . Not less than 99% is found.

Theobromine, $\text{C}_7\text{H}_8\text{N}_4\text{O}_2$ —**180.17** [83-67-0]—White, crystalline solid. Very slightly soluble in water and in alcohol; almost insoluble in benzene, in ether, and in chloroform.

Assay—Dissolve about 34 mg, accurately weighed, in 50 mL of glacial acetic acid. Titrate with 0.1 N perchloric acid VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N perchloric acid is equivalent to 18.02 mg of $\text{C}_7\text{H}_8\text{N}_4\text{O}_2$. Not less than 95% is found.

Thiazole Yellow (CI Direct Yellow 9; Clayton Yellow; Titan Yellow), $\text{C}_{28}\text{H}_{19}\text{N}_5\text{Na}_2\text{O}_6\text{S}_4$ —**695.74** [1829-00-1]—Yellowish-brown powder. Soluble in water and in alcohol to yield in each instance a yellow solution; soluble in dilute alkali to yield a brownish-red solution. Protect from light.

Solubility—A 200-mg portion mixed with 50 mL of water shows not more than a faint haze.

Residue on ignition—Accurately weigh about 1.5 g, previously dried at 105° for 2 hours, and ignite until thoroughly charred. Cool, add 2 mL of nitric acid and 2 mL of sulfuric acid, ignite gently to expel excess acids, then at 600° to 800° to constant weight: the residue of sodium sulfate (Na_2SO_4) is between 19.8% and 21.5% of the weight of the test specimen (theory is 20.4%).

Sensitiveness to magnesium—Add 0.2 mL of a solution (1 in 10,000) and 2 mL of 1 N sodium hydroxide to a mixture of 9.5 mL of water and 0.5 mL of a solution prepared by dissolving 1.014 g of clear crystals of magnesium sulfate in water, diluting with water to 100 mL, then diluting 10 mL of the resulting solution with water to 1 L: a distinct pink color is produced within 10 minutes.

Thioacetamide, $\text{C}_2\text{H}_5\text{NS}$ —**75.13** [62-55-5]—Use ACS reagent grade.

2-Thiobarbituric Acid, $\text{C}_4\text{H}_4\text{N}_2\text{O}_2\text{S}$ —**144.15** [504-17-6]—White leaflets. Slightly soluble in water.

Melting temperature (741): 236° , with decomposition.

2,2'-Thiodiethanol, $(\text{HOCH}_2\text{CH}_2)_2\text{S}$ —**122.19** [111-48-8]—Pale yellow to colorless liquid.

Assay—Not less than 98% of $\text{C}_4\text{H}_4\text{N}_2\text{O}_2\text{S}$ is found, a suitable gas chromatograph equipped with a flame-ionization detector being used. The following conditions have been found suitable: a 4.0-mm \times 1.83-m glass column is packed with 10% phase G25 on support S1A; the column, injection port, and detector temperatures are maintained at 200° , 250° , and 310° , respectively.

Refractive index (831): between 1.4250 and 1.4270, at 20° .

Thioglycolic Acid, HSCH_2COOH —**92.12** [68-11-1]—A colorless or nearly colorless liquid. Miscible with water. Soluble in alcohol.

Sensitiveness—Mix 1 mL with 2 mL of stronger ammonia water, and dilute with water to 20 mL. Add 1 mL of this solution to a mixture of 20 mL of water and 0.1 mL of dilute ferric chloride TS (1 in 100), then add 5 mL of ammonia TS: a distinct pink color is produced.

Thionine Acetate, $\text{C}_{12}\text{H}_9\text{N}_3\text{S} \cdot \text{C}_2\text{H}_4\text{O}_2$ —**287.34** [78338-22-4]—Use a suitable grade.

Thiourea, $(\text{NH}_2)_2\text{CS}$ —**76.12** [62-56-6]—Use ACS reagent grade.

Thorium Nitrate, $\text{Th}(\text{NO}_3)_4 \cdot 4\text{H}_2\text{O}$ —**552.12** [13823-29-5]—Use ACS reagent grade.

Thrombin Human (Factor II_a)—**~33,600** [9002-04-4]—A preparation of a serine protease (enzyme) that converts human fibrinogen into fibrin. It is obtained from human plasma and may be prepared by precipitation with suitable salts and organic solvents under controlled

conditions of pH, ionic strength, and temperature. A yellowish-white powder, freely soluble in a 9 g per L solution of sodium chloride, which forms a cloudy, pale yellow solution. Store in a sealed, sterile container under nitrogen, protected from light, at a temperature below 0°. One unit corresponds to the amount of enzyme that hydrolyzes 1 μ mol of Tos-Gly-Pro-Arg-4-nitroaniline acetate per minute at a pH of 8.4 and a temperature of 37°.

Thromboplastin [9035-58-9]—Buff-colored powder, or opalescent or turbid suspension. It exhibits thrombokinase activity derived from the acetone-extracted brain and/or lung tissue of freshly killed rabbits. It may contain sodium chloride and calcium chloride in suitable proportions, and it may contain a suitable antimicrobial agent. It is used in suspension form for the determination of the prothrombin time and activity of blood. Its thrombokinase activity is such that it gives a clotting time of 11 to 16 seconds with normal human plasma and the proper concentration of calcium ions. Store in tight containers, preferably at a temperature below 5°.

Loss on drying (731)—[NOTE—This test is applicable only to the dry form.] Dry it in vacuum at 60° for 6 hours: it loses not more than 5.0% of its weight.

Thymidine, $C_{10}H_{14}N_2O_5$ —**242.2** [50-89-5]—White powder. Use a suitable grade.

Thymol, $C_6H_3[CH_3][OH][CH(CH_3)_2]_{1,3,4}$ —**150.22** [89-83-8]—Colorless, often large, crystals, or a white, crystalline powder. Is affected by light. Has greater density than water, but when liquefied by fusion is less dense than water. Its alcohol solutions are neutral to litmus. One g dissolves in about 1000 mL of water, in 1 mL of alcohol, in 1 mL of chloroform, in 1.5 mL of ether, and in about 2 mL of olive oil. Soluble in glacial acetic acid and in fixed or volatile oils. Store in tight, light-resistant containers.

Melting range (741): between 48° and 51°, but when melted it remains liquid at a considerably lower temperature.

Nonvolatile matter—Volatilize 2 g on a steam bath, and dry at 105° to constant weight: the residue weighs not more than 1 mg (0.05%).

Thyroglobulin, [9010-34-8]—A protein having a molecular weight of 670 kDa. Available as a slightly beige, freeze-dried powder made from bovine or porcine thyroid gland. Use a suitable grade.

Tin, Sn—At. Wt. **118.71** [7440-31-5]—Use ACS reagent grade.

Titanium Tetrachloride, $TiCl_4$ —**189.68** [7550-45-0]—Clear, colorless liquid. Fumes in air. [CAUTION—It reacts violently with water.]

Assay—Accurately weigh 0.75 g into 100 mL of 2 N sulfuric acid contained in a Smith weighing buret. Pour the solution through a zinc–mercury reduction column into 50 mL of 0.1 N ferric ammonium sulfate VS. Elute with 100 mL of 2 N sulfuric acid and 100 mL of water. Add 10 mL of phosphoric acid, and titrate with 0.1 N potassium permanganate VS. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N potassium permanganate is equivalent to 18.97 mg of $TiCl_4$. Not less than 99.5% is found.

Boiling range (Reagent test): between 135° and 140°.

Titanium Trichloride (*Titanous Chloride*), $TiCl_3$ —**154.23** [7705-07-9]—Black, hygroscopic powder, unstable in air. Soluble in water, the solution depositing titanic acid on exposure to air. Is available usually as 15% to 20%, dark violet-blue, aqueous solutions. Store the solution in tightly closed, glass-stoppered bottles, protected from light.

o-Tolidine (4,4'-Diamino-3,3'-dimethylbiphenyl), $(NH_2)(CH_3)_2C_6H_3 \cdot C_6H_3(CH_3)(NH_2)_{4,3,3',4'}$ —**212.29** [119-93-7]—White to reddish crystals or crystalline powder. Slightly soluble in water; soluble in alcohol, in ether, and in dilute acids. Preserve in well-closed containers, protected from light. [CAUTION—Avoid contact with o-tolidine and mixtures containing o-tolidine, and conduct all tests in a well-ventilated fume hood.]

Melting range (741): between 129° and 131°.

Tolualdehyde (*o-Tolualdehyde*), C_8H_8O —**120.15** [529-20-4]—Use a suitable grade.

p-Tolualdehyde, C_8H_8O —**120.15** [104-87-0]—Colorless to yellow, clear liquid.

Assay—When examined by gas-liquid chromatography, it shows a purity of not less than 98%. The following conditions have been found suitable for assaying the article: A 3-mm \times 1.8-m stainless steel column packed with a 5% phase G4 on support S1. Nitrogen, having a flow rate of about 12 mL per minute, is the carrier gas, the detector and column temperature are about 125°, and the injection port temperature is about 205°. A flame-ionization detector is employed and the specimen is a 5% solution in carbon disulfide.

Refractive index (831): between 1.544 and 1.546, at 20°.

Toluene (*Toluol*), $C_6H_5CH_3$ —**92.14** [108-88-3]—Use ACS reagent grade.

p-Toluenesulfonic Acid, $CH_3C_6H_4SO_3H \cdot H_2O$ —**190.22** [6192-52-5]—Use ACS reagent grade.

p-Toluenesulfonyl-L-arginine Methyl Ester Hydrochloride (*N α -p-Tosyl-L-arginine methyl ester hydrochloride; TAME*), $C_{14}H_{22}N_4O_4S \cdot HCl$ —**378.88** [1784-03-8]—Determine its suitability as directed in the test for *Trypsin* under *Chymotrypsin* (USP monograph).

p-Toluic Acid, $CH_3C_6H_4COOH$ —**136.15** [99-94-5]—White, crystalline powder. Sparingly soluble in hot water; very soluble in alcohol, in methanol, and in ether.

Assay—Transfer about 650 mg, accurately weighed, to a suitable container, dissolve in 125 mL of alcohol, add 25 mL of water, and mix. Titrate with 0.5 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.5 N sodium hydroxide is equivalent to 68.07 mg of $C_8H_8O_2$: not less than 98% is found.

Melting range (741): over a range of 2° that includes 181°.

o-Toluidine (*2-Aminotoluene; 2-Methylaniline*), $C_6H_4(CH_3)(NH_2)_{1,2}$ —**107.15** [95-53-4]—Light yellow liquid becoming reddish brown on exposure to air and light. Soluble in alcohol, in ether, and in dilute acids; slightly soluble in water. Preserve in well-closed containers, protected from light.

Specific gravity (841): 1.008 at 20°.

Boiling range (Reagent test): between 200° and 202°.

p-Toluidine, C_7H_9N —**107.15** [106-49-0]—White to beige crystals or flakes.

Freely soluble in alcohol, in acetone, in methanol, and in dilute acids; slightly soluble in water.

Assay—Dissolve 400 mg, accurately weighed, in 100 mL of glacial acetic acid, and titrate with 0.1 N perchloric acid VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N perchloric acid is equivalent to 10.72 mg of $CH_3C_6H_4NH_2$. Not less than 98%, calculated on the dried basis, is found.

Loss on drying—Weigh accurately about 1 g, and dry at 30° to constant weight: it loses not more than 2% of its weight.

Toluidine Blue, $(C_{15}H_{16}ClN_3S)_2 \cdot ZnCl_2$ —**747.95** [6586-04-5]—Use a suitable grade.

Toluidine Blue O, $C_{15}H_{16}N_3S$ —**305.8** [92-31-9]—Use a suitable grade.

***n*-Triacontane**, $C_{30}H_{62}$ —**422.81** [638-68-6]—Use a suitable grade.

2,4,6-Triamino-5-nitrosopyrimidine, $C_4H_6N_6O$ —**154.13**—Pink powder.

Assay—Dissolve about 34 mg, accurately weighed, in 50 mL of glacial acetic acid. Titrate with 0.1 N perchloric acid VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary corrections. Each mL of 0.1 N perchloric acid is equivalent to 15.41 mg of $C_4H_6N_6O$. Not less than 97% is found.

Tributyl Phosphate (*Tri-*n*-butyl Phosphate*), $(C_4H_9)_3PO_4$ —**266.31** [126-73-8]—Clear, almost colorless liquid. Slightly soluble in water. Miscible with common organic solvents. Specific gravity: about 0.976.

Refractive index (831): between 1.4205 and 1.4225.

Tributylethylammonium Hydroxide, $C_{14}H_{33}NO$ —**231.42**—Use a suitable grade.

Tributylin (*Glyceryl Tributrylate*), $C_{15}H_{26}O_6$ —**302.36** [60-01-5]—Colorless, oily liquid. Insoluble in water; very soluble in alcohol and in ether.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, nitrogen being used as the carrier gas. The following conditions have been found suitable: a 3-mm \times 1.8-m stainless steel column containing phase G4 on support S1A; the injection port temperature is maintained at 270°; and the detector temperature is maintained at 300°. The area of the tributyrin peak is not less than 98% of the total peak area.

Refractive index (831): between 1.4345 and 1.4365 at 20°.

Acid content—Transfer 1.0 g, accurately weighed, to a beaker, add 75 mL of methanol, and dissolve by stirring. When dissolution is complete, add 25 mL of water, and titrate with 0.05 N potassium hydroxide VS, using phenolphthalein TS as the indicator. Perform a blank determination, and make any necessary correction. Each mL of 0.05 N potassium hydroxide is equivalent to 88.1 mg of butyric acid: not more than 0.5% is found.

Trichloroacetic Acid, CCl_3COOH —**163.39** [76-03-9]—Use ACS reagent grade.

Trichloroethane—See *Methyl Chloroform*.

Trichlorofluoromethane, CCl_3F —**137.37** [75-69-4]—Colorless liquid.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a thermal conductivity detector, helium being used as the carrier gas. The following conditions have been found suitable: a 2.0-mm \times 1.8-m glass column packed with 10% G1 phase on support S1A; the injection port temperature is maintained at 50°; the detector temperature is maintained at 300°; and the column temperature is maintained at 0° and programmed to rise 3° per minute to 50°. The area of the CCl_3F peak is not less than 99% of the total peak area.

Refractive index (831): between 1.380 and 1.384 at 20°.

Trichlorotrifluoroethane—Use a suitable grade.

[NOTE—A suitable preparation, listed as "Freon-TF aerosol," is available from E. I. du Pont de Nemours and Co., Wilmington, DE 19898.]

***n*-Tricosane**, $C_{23}H_{48}$ —**324.63** [638-67-5]—Colorless or white, more or less translucent mass, showing a crystalline structure. Has a slightly greasy feel. Insoluble in water and in alcohol; soluble in chloroform, in ether, in volatile oils, and in most warm fixed oils; slightly soluble in dehydrated alcohol. Boils at about 380°.

Melting range (741): between 47° and 49°.

Suitability—Determine its suitability for use in the test for *Related compounds* under *Propoxyphene Hydrochloride* (USP monograph) as follows. Dissolve a suitable quantity in chloroform to yield a solution containing 20 μ g per mL. Following the directions given in the test for *Related compounds* under *Propoxyphene Hydrochloride*, inject a suitable volume of the solution into the chromatograph, and record the chromatogram. Concomitantly record the chromatogram from the *Standard preparation* prepared as directed in the test for *Related compounds*: only one main peak is obtained from the *n*-tricosane solution, and no minor peaks are observed at, or near, the peak positions obtained for propoxyphene, acetoxy, or carbinol in the chromatogram from the *Standard preparation*.

Triethanolamine—Use *Trolamine* (NF monograph).

Triethylamine, $(C_2H_5)_3N$ —**101.19** [121-44-8]—Colorless liquid. Slightly soluble in water. Miscible with alcohol, with ether, and with cold water. Store in well-closed containers. Use a suitable grade with a content of not less than 99.5%.

Triethylamine Hydrochloride, $C_6H_{15}N \cdot HCl$ —**137.65** [554-68-7]—White to off-white powder.

Assay—Transfer about 35 mg, accurately weighed, to a suitable beaker, add 50 mL of glacial acetic acid, and dissolve by stirring. Add 5 mL of mercuric acetate TS, with stirring. When solution is complete, titrate with 0.1 N perchloric acid VS, determining the endpoint potentiometrically. Perform a blank titration, and make any necessary correction. Each mL of 0.1 N perchloric acid is equivalent to 13.77 mg of $C_6H_{15}N \cdot HCl$. Not less than 97.5% of $C_6H_{15}N \cdot HCl$ is found.

Melting point (741): between 256° and 259°, with decomposition.

Triethylamine Phosphate (*Triethylammonium Phosphate*), $C_6H_{15}N \cdot H_3O_4P$ —**199.19**—Use a suitable grade.

[NOTE—A suitable grade is available from www.tciamerica.com, catalog number T1300.]

Triethylene Glycol, $C_6H_{14}O_4$ —**150.17** [112-27-6]—Colorless to pale yellow liquid. Is hygroscopic. Miscible with water, with alcohol, and with toluene.

Assay—Inject an appropriate test specimen into a suitable gas chromatograph equipped with a flame-ionization detector (see *Chromatography* (621)), helium being used as the carrier gas. The following conditions have been found suitable: a 3-mm \times 1.85-m stainless steel column packed with support S2; the injection port, column, and detector temperatures are maintained at 250°, 230°, and 310°, respectively. The area of the $C_6H_{14}O_4$ peak is not less than 97% of the total peak area.

Refractive index (831): between 1.4550 and 1.4570, at 20°.

Triethylenediamine (*1,4-Diazobicyclo[2.2.2]octane*), $C_6H_{12}N_2$ —**112.17** [280-57-9]—Use a suitable grade with a content of not less than 98%.

Trifluoroacetic Acid, $C_2HF_3O_2$ —**114.02** [76-05-1]—Colorless liquid. Miscible with ether, with acetone, with ethanol, with benzene, with carbon tetrachloride, and with hexane.

Assay—Dissolve about 300 mg, accurately weighed, in 25 mL of water and 25 mL of alcohol. Titrate with 0.1 N sodium hydroxide VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary corrections. Each mL of 0.1 N sodium hydroxide is equivalent to 11.40 mg of $C_2HF_3O_2$. Not less than 99% is found.

Trifluoroacetic Anhydride, $(F_3CCO)_2O$ —**210.03** [407-25-0]—Colorless liquid. Boils between 40° and 42°. Extremely volatile. Avoid exposure to air or water.

Assay—Transfer about 0.8 g, accurately weighed, to a glass-stoppered flask containing 50 mL of methanol. Add 500 mg of phenolphthalein, and titrate with 0.1 N sodium

methoxide VS to a pink endpoint. Calculate A by the formula:

$$V/W$$

in which V is the volume, in mL, of 0.1 N sodium methoxide and W is the weight, in mg, of test specimen. To a second glass-stoppered flask containing 50 mL of a mixture of dimethylformamide and water (1:1) transfer 0.4 g, accurately weighed, of the specimen under test, add 500 mg of phenolphthalein, and titrate with 0.1 N sodium hydroxide VS to a pink endpoint. Calculate B by the formula:

$$V^1/W^1$$

in which V¹ is the volume, in mL, of 0.1 N sodium hydroxide and W¹ is the weight, in mg, of test specimen. Calculate the percentage of (F₃CCO)₂O by the formula:

$$2100.3(B - A)$$

Not less than 97% is found. If 2A is greater than B, calculate the percentage of F₃CCOOH by the formula:

$$1140.3(2A - B)$$

α,α,α-Trifluoro-p-cresol (4-hydroxybenzotrifluoride, 4-trifluoromethylphenol), C₇H₅F₃O—**162.11** [402-45-9]

Melting range (741): between 48° and 52°.

2,2,2-Trifluoroethanol, CF₃CH₂OH—**100.04** [75-89-8]—Colorless liquid.

Assay—Inject an appropriate specimen into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm × 30-m capillary column coated with a 1-μm layer of phase G2; the injection port temperature is maintained at 100°; the detector temperature is maintained at 150°; and the column temperature is maintained at 0° and programmed to rise 10° per minute to 150°. The area of the CF₃CH₂OH peak is not less than 99% of the total peak area.

Boiling range: between 77° and 80°.

2,2,2-Trifluoroethyldifluoromethyl Ether (Difluoromethyl-2,2,2-trifluoroethyl ether), C₃H₃F₅O—**150.05**—Clear liquid. Use a suitable grade.

Boiling range: between 28° and 30°.

[NOTE—A suitable grade is available from PCR Incorporated, P.O. Box 1466, Gainesville, FL 32602. Tel: 904-376-8246. The catalogue number is 17151-2.]

(m-Trifluoromethylphenyl) Trimethylammonium Hydroxide in Methanol—Use a suitable grade.

[NOTE—A suitable grade is available as "Meth-Prep II" from Alltech, www.alltechweb.com.]

5-(Trifluoromethyl)uracil, C₅H₃F₃N₂O₂—**180.08** [54-20-6]—White to off-white powder.

Assay—When tested by thin-layer chromatography, with the use of plates coated with chromatographic silica gel mixture, a developing system consisting of chloroform, methanol, and acetic acid (17:2:1), and examined visually and under long-wavelength UV light, a single spot is exhibited.

Trifluorovinyl Chloride Polymer (Fluorolube; 1-Chloro-1,2,2-trifluoro-ethene Homopolymer), (C₂ClF₃)_x—Use a suitable grade.

[NOTE—A suitable grade is available as catalog number Z123552 from www.sigma-aldrich.com.]

Trimethylacetylhydrazide Ammonium Chloride (Betaine Hydrazide Chloride; Girard Reagent T), [(CH₃)₃N⁺CH₂CONHNH₂]Cl—**167.64** [123-46-6]—Colorless or white crystals. Freely soluble in water. One g dissolves in about 25 mL of alcohol. Insoluble in chloroform and in ether. Hygroscopic.

Melting range (741): between 185° and 192°, determined after recrystallization from hot alcohol, if necessary.

Residue on ignition (Reagent test)—Ignite 1 g with 0.5 mL of sulfuric acid: the residue weighs not more than 10 mg (1%).

Trimethylchlorosilane—See *Chlorotrimethylsilane*.

2,2,4-Trimethylpentane (Isooctane), C₈H₁₈—**114.23** [540-84-1]—Use ACS reagent grade.

2,4,6-Trimethylpyridine (5-Collidine), C₈H₁₁N—**121.18** [108-75-8]—Clear, colorless liquid. Soluble in cold water and less soluble in hot water; soluble in alcohol, in chloroform, and in methanol. Miscible with ether.

Assay—Inject an appropriate test specimen into a suitable gas chromatograph (see *Chromatography* (621)), helium being used as a carrier gas. The following conditions have been found suitable: a 3-mm × 1.85-m stainless steel column containing phase G16 on support S1A; the injection port, column, and detector temperatures are maintained at 180°, 165°, and 270°, respectively; and a flame-ionization detector is used. The area of the C₈H₁₁N peak is not less than 98% of the total peak area.

Refractive index (831): between 1.4970 and 1.4990, at 20°.

N-(Trimethylsilyl)-imidazole, C₆H₁₂N₂Si—**140.26** [18156-74-6]—A clear, colorless, to light yellow liquid.

Refractive index (831): between 1.4744 and 1.4764 at 20°.

Trimethyltin Bromide, C₃H₉BrSn—**243.72** [1066-44-0]—Use a suitable grade.

2,4,6-Trinitrobenzenesulfonic Acid, C₆H₂(NO₂)₃SO₃H · 3H₂O—**347.21** [2508-19-2]—Pale yellow to tan crystals. Use a suitable grade. Also available as a 5% (w/v) or a 1 M aqueous solution.

Trinitrophenol—See *Picric Acid*.

Trioctylphosphine Oxide, C₂₄H₅₁PO—**386.63**

[78-50-2]—White, crystalline powder. Insoluble in water; soluble in organic solvents.

Melting range (741): between 54° and 56°.

1,3,5-Triphenylbenzene, (C₆H₅)₃C₆H₃—**306.41** [612-71-5]—White to off-white powder.

Melting range (741): between 172° and 175°.

Triphenylmethane, C₁₉H₁₆—**244.34** [519-73-3]—Light brown powder.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm × 30-m capillary column coated with a 1-μm layer of phase G2; the injection port temperature is maintained at 300°; the detector temperature is maintained at 300°; and the column temperature is maintained at 200° and programmed to rise 10° per minute to 300°. The area of the C₁₉H₁₆ peak is not less than 99% of the total peak area.

Melting range (741): between 92° and 94°.

Triphenylmethanol, C₁₉H₁₆O—**260.34** [76-84-6]—White to off-white powder.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm × 30-m capillary column coated with a 1-μm layer of phase G2; the injection port temperature is maintained at 280°; the detector temperature is maintained at 300°; and the column temperature is maintained at 180°. The area of the C₁₉H₁₆O peak is not less than 96.5% of the total peak area.

Triphenyltetrazolium Chloride, C₁₉H₁₅ClN₄—**334.80**

[298-96-4]—White to yellowish, crystalline powder. Soluble in about 10 parts of water and of alcohol; slightly soluble in acetone; insoluble in ether. Usually contains solvent of crystallization, and when dried at 105° it melts at about 240°, with decomposition.

Solubility—Separate 100-mg portions dissolve completely in 10 mL of water and in 10 mL of alcohol, respectively, to yield solutions that are clear, or practically so.

Loss on drying (731)—Dry it at 105° to constant weight: it loses not more than 5.0% of its weight.

Residue on ignition (Reagent test): negligible, from 100 mg.

Sensitiveness—Dissolve 10 mg in 10 mL of dehydrated alcohol (A). Then dissolve 10 mg of dextrose in 20 mL of dehydrated alcohol (B). To 0.2 mL of B add 1 mL of dehydrated alcohol and 0.5 mL of dilute tetramethylammonium hydroxide TS (1 volume diluted with 9 volumes of dehydrated alcohol), then add 0.2 mL of A: a pronounced red color develops within about 10 minutes.

Tris(2-aminoethyl)amine, $C_6H_{18}N_4$ —**146.23**

[4097-89-6]—Yellow liquid. Soluble in methanol.

Assay—Dissolve about 80 mg in 30 mL of methanol. Add 40 mL of water, and titrate with 1 N hydrochloric acid, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 1 N hydrochloric acid is equivalent to 48.75 mg of $C_6H_{18}N_4$. Not less than 98.0% is found.

Refractive index (831): between 1.4956 and 1.4986 at 20°.

Tris(hydroxymethyl)aminomethane [77-86-1]—Use ACS reagent grade—See also *Tromethamine*.

Tris(hydroxymethyl)aminomethane Acetate, $C_4H_{11}O_3 \cdot NCH_3$ —**181.19** [6850-28-8]—White powder with lumps. Use a suitable grade.

Tris(hydroxymethyl)aminomethane Hydrochloride, $C_4H_{11}NO_3 \cdot HCl$ —**157.60** [1185-53-1]—Colorless crystals. Use a suitable grade.

N-Tris(hydroxymethyl)methylglycine, $C_6H_{13}NO_5$ —**179.2** [5704-04-1]—White, crystalline powder. Use a suitable grade.

Tritirachium Album Proteinase K—Use a suitable grade.

[NOTE—A suitable grade can be obtained from Qiagen, Inc., www.qiagen.com.]

Tromethamine [*Tris(hydroxymethyl)aminomethane*; *THAM*; 2-Amino-2-(hydroxymethyl)-1,3-propanediol], $C_4H_{11}NO_3$ —**121.14**—Use ACS reagent grade *Tris(hydroxymethyl)aminomethane*.

Tropaeolin OO (*Acid Orange 5*), $C_{18}H_{14}N_3NaO_3S$ —**375.38** [554-73-4]—Orange-yellow scales, or yellow powder. Soluble in water.

pH range: from 1.4 (red) to 2.6 (yellow).

Tropic Acid, $C_9H_{10}O_3$ —**166.18** [529-64-6]—Use a suitable grade.

Tropine, $C_8H_{15}NO$ —**141.2** [120-29-6]—Use a suitable grade.

Trypan Blue (*Direct Blue 14*), $C_{34}H_{24}N_6Na_4O_{14}S_4$ —**960.8** [72-57-1]—Use a suitable grade.

Tryptone—Use *Pancreatic Digest of Casein*.

L-Tryptophane, $C_{11}H_{12}N_2O_2$ —**204.23** [73-22-3]—White or not more than slightly yellow leaflets or powder. One g dissolves in about 100 mL of water; soluble in dilute acids and in solutions of the alkali hydroxides; slightly soluble in alcohol.

Assay—Accurately weigh about 300 mg, dissolve in a mixture of 3 mL of formic acid and 50 mL of glacial acetic acid, add 2 drops of crystal violet TS, and titrate with 0.1 N perchloric acid VS to a green endpoint. Each mL of 0.1 N perchloric acid is equivalent to 20.42 mg of $C_{11}H_{12}N_2O_2$. Between 98.0% and 102.0%, calculated on the dried basis, is found.

Specific rotation (781): between -30.0° and -33.0° , determined in a solution containing 1.0 g of test specimen, previously dried at 105° for 3 hours, in 100 mL.

Loss on drying (731)—Dry it at 105° for 3 hours: it loses not more than 0.3% of its weight.

Residue on ignition (Reagent test): not more than 0.1%.

Tyrosine—Dissolve 100 mg in 3 mL of diluted sulfuric acid, add 10 mL of mercuric sulfate TS, and heat on a steam bath for 10 minutes. Filter, wash with 5 mL of mercuric sul-

fate TS, and add to the combined filtrate 0.5 mL of sodium nitrite solution (1 in 20): no red color is produced within 15 minutes.

Tuberculin, Purified Protein Derivative (*Tuberculin PPD*)—Derived from the human strain of *Mycobacterium tuberculosis*, and available either as a solution or as a lyophilized powder. For lyophilized powder, reconstitute according to the manufacturer's instructions using the diluent provided by the manufacturer. Solutions may contain a stabilizer and a preservative. One Tuberculin Unit (TU) is equivalent to 0.02 μ g of Tuberculin PPD.

Tubocurarine Chloride (*7',12'-Dihydroxy-6,6'-dimethoxy-2,2',2'-trimethyltubocurarium Chloride*), $C_{37}H_{42}Cl_2N_2O_6$ —**681.65** [6989-98-6]—Use a suitable grade with an assay result between 98.0% and 102.0%.

[NOTE—A suitable grade is available from Acros Organics, catalog number 24349 at www.acros.com.]

Tungstic Acid, H_2WO_4 —**249.85** [7783-03-1]—Use a suitable grade with a content of not less than 99%.

L-Tyrosine Disodium, $C_9H_9NO_3Na_2$ —**225.2**

[69849-45-6]—Off-white to tan powder. Use a suitable grade.

Uracil, $C_4H_4N_2O_2$ —**112.09** [66-22-8]—White to cream-colored, crystalline powder. Melts above 300°. One g dissolves in about 500 mL of water; less soluble in alcohol; soluble in ammonia TS and in sodium hydroxide TS. Its solutions yield no precipitate with the usual alkaloidal precipitants.

Residue on ignition (Reagent test): negligible, from 100 mg.

Loss on drying (731)—Dry it at 105° for 2 hours: it loses not more than 2% of its weight.

Uranyl Acetate (*Uranium Acetate*), $UO_2(C_2H_3O_2)_2 \cdot 2H_2O$ —**424.15** [541-09-3]—Use ACS reagent grade.

Urea, NH_2CONH_2 —**60.06** [57-13-6]—Use ACS reagent grade.

Urethane (*Ethyl carbamate*), $C_3H_7NO_2$ —**89.09**

[51-79-6]—White powder with chunks. Freely soluble in water.

Melting range (741): between 48° and 50°.

Uridine, $C_9H_{12}N_2O_6$ —**244.20** [58-96-8]—White powder.

Assay—

MOBILE PHASE—Prepare a mixture of methanol and 0.2 M ammonium acetate (10:90), and adjust with phosphoric acid to a pH of 7.0.

TEST SOLUTION: 0.5 mg per mL in water.

PROCEDURE—Inject about 20 μ L of the *Test solution* into a liquid chromatograph (see *Chromatography* (621)), equipped with a 280-nm detector and a 4.6-mm \times 15-cm column that contains packing L1. The flow rate is about 2.0 mL per minute. The area of the $C_9H_{12}N_2O_6$ peak is not less than 99% of the total peak area.

Melting range (741): between 166° and 171°.

Valeric Acid, $C_5H_{10}O_2$ —**102.13** [109-52-4]—Clear, colorless liquid.

Assay—Accurately weigh about 500 mg, transfer to a suitable container, add 30 mL of water, and mix. Add 40 mL of water, and mix. Add phenolphthalein TS, and titrate with 0.1 N sodium hydroxide VS. Each mL of 0.1 N sodium hydroxide is equivalent to 10.21 mg of $C_5H_{10}O_2$: not less than 99.0% of $C_5H_{10}O_2$ is found.

Valerophenone, $C_{11}H_{14}O$ —**162.23** [1009-14-9]—Colorless liquid.

Assay—Inject an appropriate specimen into a suitable gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a capillary column coated with a 1- μ m layer of phase G2; the injection port temperature is maintained at 250°; the detector temperature is maintained at 300°; and the column temperature is maintained at 150° and programmed to rise 10°

per minute to 300°. The area of the $C_{11}H_{14}O$ peak is not less than 98% of the total peak area.

Refractive index (831): 1.5149 at 20°.

Boiling range: between 105° and 107°, at a pressure of 5 mm of mercury.

Vanadium Pentoxide, V_2O_5 —**181.88** [1314-62-1]—Fine, yellow to orange-yellow powder. Slightly soluble in water; soluble in concentrated acids and in alkalis; insoluble in alcohol.

Assay—Transfer about 400 mg, accurately weighed, to a 500-mL conical flask, and add 150 mL of water and 30 mL of dilute sulfuric acid (1 in 2). Boil the solution on a hot plate for 5 minutes, add 50 mL of water, and continue boiling until a yellow solution is obtained. Transfer the hot plate and the flask to a well-ventilated hood, and bubble sulfur dioxide gas through the solution for 10 minutes, or until the solution is a clear, brilliant blue color. Rinse the gas delivery tube into the flask with a few mL of water, then bubble carbon dioxide gas through the solution for 30 minutes while continuing to boil the solution gently. Cool the solution to about 80°, and titrate with 0.1 N potassium permanganate VS to a yellow-orange endpoint. Perform a complete blank determination, and make any necessary correction. Each mL of 0.1 N potassium permanganate is equivalent to 9.095 mg of V_2O_5 . Not less than 99.5% is found.

Vanadyl Sulfate, $VOSO_4 \cdot xH_2O$ (anhydrous)—**163.00** [27774-13-6]—Blue, hygroscopic crystals. Slowly and usually incompletely soluble in water.

Assay—Accurately weigh about 400 mg of the dried test specimen obtained in the test for *Water*, and transfer with 15 to 20 mL of water into a beaker. Add 3 mL of sulfuric acid, cover the beaker with a watch glass, and heat on a steam bath until all dissolves. Cool, dilute with 125 mL of water, and titrate with 0.1 N potassium permanganate VS to the production of a pinkish color that persists for 1 minute: each mL of 0.1 N potassium permanganate is equivalent to 16.30 mg of $VOSO_4$. Not less than 97% is found.

Water—Dry about 1 g, accurately weighed, at 220° to constant weight: it loses not more than 50.0% of its weight.

Pentavalent vanadium—Heat 1 g, accurately weighed, with 50 mL of water and 5 mL of hydrochloric acid in a flask until dissolved. Cool, add 2 g of potassium iodide, insert the stopper, and allow to stand for 30 minutes. Add 50 mL of water, and titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the indicator. Correct for the volume of thiosulfate consumed by a blank. Each mL of 0.1 N thiosulfate is equivalent to 5.095 mg of vanadium (V). Not more than 0.5% is found, calculated on the dried basis.

Substances not precipitated by ammonia—Dissolve 1.0 g by heating with 20 mL of water and 2 mL of hydrochloric acid. Dilute with water to about 75 mL, and neutralize to litmus paper with ammonia TS. Transfer the solution to a cylinder, slowly add 5 mL of ammonia TS and sufficient water to make 100 mL, and allow to stand overnight. Decant 50 mL of the supernatant through a filter, add 5 drops of sulfuric acid, evaporate to dryness, and ignite: the residue weighs not more than 10 mg (2.0%).

Vinyl Acetate, $CH_3COOCH=CH_2$ —**86.09** [108-05-4]—Liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of G2; the injection port temperature is maintained at 100°; the detector temperature is maintained at 300°; and the column temperature is maintained at 100° and programmed to rise 10° per minute to 150°. The area of the

$CH_3COOCH=CH_2$ peak is not less than 99% of the total peak area.

2-Vinylpyridine, C_7H_7N —**105.14** [100-69-6].

Boiling range: between 79° and 82°, at 29 mm of mercury.

Density: 0.975 at 25°.

Refractive index (831): about 1.5490 at 20°.

Vinylpyrrolidinone (1-Vinyl-2-pyrrolidinone; 1-Vinyl-2-pyrrolidone; N-Vinylpyrrolidinone; N-Vinylpyrrolidone), C_6H_9NO —**111.14** [88-12-4]—Colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of G2; the injection port temperature is maintained at 250°; the detector temperature is maintained at 300°; and the column temperature is maintained at 100° and programmed to rise 10° per minute to 250°. The area of the C_6H_9NO peak is not less than 99.0% of the total peak area.

Water, Method 1 (921): not more than 0.1%, determined on 2.5 g, using a mixture of 50 mL of methanol and 10 mL of butyrolactone as the solvent.

[NOTE—A suitable grade is available from Merck KGaA/EMD chemicals, catalogue number 8.08518.0250, www.emdchemicals.com.]

Washed Sand—See *Sand, Washed*.

Water, Ammonia-Free, H_2O —**18.02**—Use *High-Purity Water* as defined for *Chemical Resistance* under *Containers—Glass* (660).

Water, Carbon Dioxide-Free—See *Water*, in the introductory section.

Water, Deaerated—See *Water*, in the introductory section.

Water Vapor Detector Tube—A fuse-sealed glass tube so designed that gas may be passed through it and containing suitable absorbing filters and support media for the indicator, which consists of a selenium sol in suspension in sulfuric acid.

Measuring range: 5 to 250 mg per cubic meter.

[NOTE—Available from Draeger Safety, Inc., www.draeger.com, or from Gastec Corp., www.gastec.co.jp, distributed in the USA by www.nextteq.com.]

Wright's Stain [68988-92-1]—A mixture of methylene blue, methylene azure, and the eosinates of both, available as a solid and as a solution in methanol. Use a suitable grade. [NOTE—If a solid is used, dissolve 6.0 g of Wright's stain powder (CAS# 68988-92-1, dark green powder) and 0.6 g of Giemsa stain powder (CAS# 51811-82-6, dark green to black powder or crystals) in 1000 mL of methanol. Stir overnight, and filter before use.]

Xanthine, $C_5H_4N_4O_2$ —**152.11** [69-89-6]—White, crystalline powder. Decomposes on heating. Slightly soluble in water and in alcohol; soluble in sodium hydroxide TS; sparingly soluble in diluted hydrochloric acid. When subjected to the murexide reaction, a purple color is produced with the ammonia, but on the subsequent addition of fixed alkali hydroxides, the color is not discharged but is changed to violet.

Residue on ignition (Reagent test): negligible, from 100 mg.

Loss on drying (731)—Dry it at 105° for 2 hours: it loses not more than 1% of its weight.

Xanthidrol, $C_{13}H_{10}O_2$ —**198.22** [90-46-0]—Pale yellow, crystalline powder. Insoluble in water; soluble in alcohol, in chloroform, and in ether. Soluble in glacial acetic acid, forming a practically colorless solution; but when the powder is treated with diluted hydrochloric acid, a lemon-yellow color is produced.

Melting range (741): between 121° and 123°.

Residue on ignition—Ignite 500 mg with 0.5 mL of sulfuric acid: the residue weighs not more than 10 mg (2.0%).

Xylene, C_8H_{10} —**106.17** [1330-20-7]—Use ACS reagent grade.

m-Xylene, $C_6H_4(CH_3)_2$ —**106.17** [108-38-3]—Clear, colorless, flammable liquid. Insoluble in water; miscible with alcohol and with ether. Use a suitable grade.

o-Xylene, C_8H_{10} —**106.17** [95-47-6]—Clear, colorless, mobile, flammable liquid. Insoluble in water; miscible with alcohol and with ether.

Assay—When examined by gas-liquid chromatography, it shows a purity of not less than 95%. The following conditions have been found suitable for assaying the substance: A 3-mm \times 1.8-m stainless steel column packed with 1.75% hydrated aluminum silicate plus 5.0% diisodecyl phthalate on support S1. Helium, having a flow rate of about 27.5 mL per minute is the carrier gas, the detector temperature is about 280°, the injection port temperature is about 180°, and the column temperature is 80°. A flame-ionization detector is employed.

Refractive index (831): between 1.5040 and 1.5060, at 20°.

p-Xylene, C_8H_{10} —**106.17** [106-42-3]—Colorless liquid.

Assay—Inject an appropriate volume into a gas chromatograph (see *Chromatography* (621)) equipped with a flame-ionization detector, helium being used as the carrier gas. The following conditions have been found suitable: a 0.25-mm \times 30-m capillary column coated with a 1- μ m layer of phase G14; the column temperature is maintained at 50° and programmed to rise 10° per minute to 100°; the injection port is maintained at 130°; and the detector is maintained at 300°. The area of the C_8H_{10} peak is not less than 99% of the total peak area.

Refractive index (831): between 1.493 and 1.497 at 20°.

Xylene Cyanole FF, $C_{25}H_{27}N_2NaO_6S_2$ —**538.61** [2650-17-1]—Gray-blue to dark blue powder. Soluble in water.

Assay—Transfer about 50 mg, accurately weighed, to a 100-mL volumetric flask, dissolve in water, dilute with water to volume, and mix. Transfer 2.0 mL of the solution to a 50-mL volumetric flask, dilute with pH 7.0 phosphate buffer to volume (See *Solutions*, in this section), and mix. Using a suitable spectrophotometer, 1-cm cells, and water as the blank, record the absorbance of the solution at the wavelength of maximum absorbance at about 614 nm. From the observed absorbance, calculate the absorptivity (see *Spectrophotometry and Light-scattering* (851)): the absorptivity is not less than 55.9, corresponding to about 83% of $C_{25}H_{27}N_2NaO_6S_2$.

Loss on drying (731)—Dry it at 110° to constant weight: it loses not more than 6.0% of its weight.

Xylose, $C_5H_{10}O_5$ —**150.13** [58-86-6]—Use a suitable grade.

Yeast Extract—A water-soluble, peptone-like derivative of yeast cells (*Saccharomyces*) prepared under optimum condi-

tions, clarified, and dried to a reddish-yellow to brown powder, having a characteristic but not putrescent odor. Soluble in water, forming a yellow to brown solution, having a slightly acid reaction. Contains no added carbohydrate. One g represents not less than 7.5 g of yeast.

Loss on drying (731)—Dry it at 105° to constant weight: it loses not more than 6% of its weight.

Residue on ignition—Ignite 500 mg with 1 mL of sulfuric acid: the residue weighs not more than 75 mg (15%).

Coagulable protein—Heat a filtered solution (1 in 20) to boiling: no precipitate is formed.

Chloride (Reagent test)—It shows not more than 5% of Cl, calculated as sodium chloride.

Nitrogen content (Reagent test)—Determine by the Kjeldahl method, using a test specimen previously dried at 105° to constant weight: between 7.2% and 13.0% of N is found.

Microbial content—NMT 10^4 cfu/g

Yellow Mercuric Oxide—See *Mercuric Oxide, Yellow*.

Zinc, Zn—**At. Wt. 65.39** [7440-66-6]—Use ACS reagent grade.

Zinc, Activated—Place zinc pellets in a conical flask, and add a sufficient quantity of a 50-ppm solution of chloroplatinic acid to cover all pellets. Allow the metal to remain in contact with the solution for 10 min, drain, wash, and dry immediately.

Assay—To 5 g of activated zinc add 15 mL of hydrochloric acid, 25 mL of water, 0.1 mL of stannous chloride solution (235 mg/mL in hydrochloric acid), and 5 mL of potassium iodide solution (166 mg/mL in water). No stain is produced when in contact with mercuric bromide paper. Repeat the test for arsenic, using the same reagents and adding a solution containing 1 μ g of arsenic. An appreciable stain appears when in contact with mercuric bromide paper.

Zinc Acetate, $Zn(CH_3COO)_2 \cdot 2H_2O$ —**219.51** [557-34-6]—Use ACS reagent grade.

Zinc Amalgam—Add 54 g of mossy or granular zinc to 100 mL of mercury in a beaker. Heat, with stirring, on a hot plate under a hood [Caution—mercury vapor is extremely toxic] until solution of the zinc is complete or practically so. Allow to cool to room temperature, and if necessary add sufficient mercury to prevent solidification of the amalgam. Transfer the amalgam to a glass-stoppered bottle, and shake a few times with dilute hydrochloric acid (1 in 2), to remove any zinc oxide formed.

Zinc Chloride, Anhydrous, Powdered—Use *Zinc Chloride* (USP monograph) that has been dried and powdered.

Zinc Sulfate Heptahydrate, $ZnSO_4 \cdot 7H_2O$ —**287.54** [7446-20-0]—Odorless crystals, granules, or powder.

Melting point (741): 100°.

Density: 1.97.

Zirconyl Chloride, Octahydrate, Basic—Use *Zirconium Oxychloride*.

Zirconyl Nitrate, $ZrO(NO_3)_2$ —**231.23** [13826-66-9]—Use a suitable grade.

Indicators and Indicator Test Papers

INDICATORS

Indicators are required in the Pharmacopeial tests and assays either to indicate the completion of a chemical reaction in volumetric analysis or to indicate the hydrogen-ion concentration (pH) of solutions. The necessary solutions of indicators are listed among the Test Solutions, abbreviated "TS."

Solutions of indicators of the basic type and of the phthalins are prepared by dissolving in alcohol. With indicators

containing an acidic group, the acid must first be neutralized with sodium hydroxide as follows:

Triturate 100 mg of the indicator in a smooth-surfaced mortar with the volume of 0.05 N sodium hydroxide specified in the directions for preparing its Test Solution, or with the equivalent of 0.02 N sodium hydroxide. When the indicator has dissolved, dilute the solution with carbon dioxide-free water to 200 mL (0.05%). Store the solutions in suitably resistant containers, protected from light.

Listed in ascending order of the lower limit of their range, useful pH indicators are: thymol blue, pH 1.2–2.8; methyl yellow, pH 2.9–4.0; bromophenol blue, pH 3.0–4.6; bromocresol green, pH 4.0–5.4; methyl red, pH 4.2–6.2; bromocresol purple, pH 5.2–6.8; bromothymol blue, pH 6.0–7.6; phenol red, pH 6.8–8.2; thymol blue, pH 8.0–9.2; and thymolphthalein, pH 8.6–10.0.

Alphazurine 2G—Use a suitable grade.

Azo Violet [4-(*p*-Nitrophenylazo)resorcinol], $C_{12}H_9N_3O_4$ —**259.22**—Red powder. It melts at about 193°, with decomposition.

Bismuth Sulfite—Use a suitable grade.

Brilliant Green—See *Brilliant Green* in the section *Reagents*.

Brilliant Yellow (C.I. 24890), $C_{26}H_{18}N_4Na_2O_8S$ —**592.49**—Orange to rust-colored powder. Soluble in water.

Loss on drying (731)—Dry it in vacuum at 60° for 1 hour: it loses not more than 5% of its weight.

Bromocresol Blue—Use *Bromocresol Green*.

Bromocresol Green (*Bromocresol Blue*; *Tetrabromo-m-cresol-sulfonphthalein*), $C_{21}H_{14}Br_4O_5S$ —**698.01**—White or pale buff-colored powder. Slightly soluble in water; soluble in alcohol and in solutions of alkali hydroxides. Transition interval: from pH 4.0 to 5.4. Color change: from yellow to blue.

Bromocresol Green Sodium Salt—Use a suitable grade.

Bromocresol Purple (*Dibromo-o-cresolsulfonphthalein*), $C_{21}H_{16}Br_2O_5S$ —**540.22**—White to pink, crystalline powder. Insoluble in water; soluble in alcohol and in solutions of alkali hydroxides. Transition interval: from pH 5.2 to 6.8. Color change: from yellow to purple.

Bromocresol Purple Sodium Salt, $C_{21}H_{15}Br_2O_5SNa$ —**562.20**—Black powder. Soluble in water. Transition interval: from pH 5.0 to 6.8. Color change: from greenish yellow to purple-violet.

Melting range (741): between 261° and 264°.

Bromophenol Blue (3',3'',5',5''-*Tetrabromophenol-sulfonphthalein*), $C_{19}H_{10}Br_4O_5S$ —**669.96**—Pinkish crystals. Insoluble in water; soluble in alcohol and in solutions of alkali hydroxides. Transition interval: from pH 3.0 to 4.6. Color change: from yellow to blue.

Bromophenol Blue Sodium—The sodium salt of 3',3'',5',5'' (*Tetrabromophenolsulfonphthalein*), $C_{19}H_9Br_4O_5SNa$ —**646.36**—Pinkish crystals. Soluble in water and in alcohol. Transition interval: from pH 3.0 to 4.6. Color change: from yellow to blue.

Bromothymol Blue (3',3''-*Dibromothymolsulfonphthalein*), $C_{27}H_{28}Br_2O_5S$ —**624.38**—Cream-colored powder. Insoluble in water; soluble in alcohol and in solutions of alkali hydroxides. Transition interval: from pH 6.0 to 7.6. Color change: from yellow to blue.

Congo Red—See *Congo Red* in the section *Reagents*.

Cresol Red (*o-Cresolsulfonphthalein*), $C_{21}H_{18}O_5S$ —**382.43**—Red-brown powder. Slightly soluble in water; soluble in alcohol and in dilute solutions of alkali hydroxides. Transition interval: from pH 7.2 to 8.8. Color change: from yellow to red.

Crystal Violet (*Hexamethyl-p-rosaniline Chloride*), $C_{25}H_{30}ClN_3$ —**407.98**—Dark-green crystals. Slightly soluble in water; sparingly soluble in alcohol and in glacial acetic acid. Its solutions are deep violet in color.

Sensitiveness—Dissolve 100 mg in 100 mL of glacial acetic acid, and mix. Pipet 1 mL of the solution into a 100-mL volumetric flask, and dilute with glacial acetic acid to volume: the solution is violet-blue in color and does not show a reddish tint. Pipet 20 mL of the diluted solution into a beaker, and titrate with 0.1 N perchloric acid VS, adding the perchloric acid slowly from a microburet: not more than 0.10 mL of 0.1 N perchloric acid is required to produce an emerald-green color.

4,5-Dihydroxy-3-(*p*-sulfophenylazo)-2,7-naphthalenedisulfonic Acid, Trisodium Salt—See 2-(4-Sulfophenylazo)-1,8-dihydroxy-3,6-naphthalenedisulfonic Acid, Trisodium Salt.

Eosin Y (*Indicator grade Eosin Y, Sodium tetrabromofluorescein*), $C_{20}H_6Br_4Na_2O_5$ —**691.86** [17372-87-1]—Red to brownish-red pieces or powder. One g dissolves in about 2 mL of water and in 50 mL of alcohol. Dye content about 80%.

Eriochrome Black T [*Sodium 1-(1-Hydroxy-2-naphthylazo)5-nitro-2-naphthol-4-sulfonate*], $C_{20}H_{12}N_3NaO_7S$ —**461.38**—Brownish-black powder having a faint, metallic sheen. Soluble in alcohol, in methanol, and in hot water.

Sensitiveness—To 10 mL of a 1 in 200,000 solution in a mixture of equal parts of methanol and water add sodium hydroxide solution (1 in 100) until the pH is 10: the solution is pure blue in color and free from cloudiness. Add 0.01 mg of magnesium ion (Mg): the color of the solution changes to red-violet, and with the continued addition of magnesium ion it becomes wine-red.

Eriochrome Black T Trituration—Grind 200 mg of eriochrome black T to a fine powder with 20 g of potassium chloride.

Litmus—Blue powder, cubes, or pieces. Partly soluble in water and in alcohol. Transition interval: from approximately pH 4.5 to 8. Color change: from red to blue. Litmus is unsuitable for determining the pH of alkaloids, carbonates, and bicarbonates.

Malachite Green Oxalate, $[C_{23}H_{25}N_2^+]_2 \cdot [C_2HO_4^-]_2 \cdot C_2H_2O_4$ —**927.00**—The oxalate salt, crystallized with oxalic acid, of a triphenylmethane dye. Dark-green powder, having a metallic luster. Sparingly soluble in water; soluble in glacial acetic acid. Transition interval: from pH 0.0 to 2.0. Color change: from yellow to green.

Methyl Orange (*Helianthin* or *Tropaeolin D*), $C_{14}H_{14}N_3NaO_3S$ —**327.33**—The sodium salt of dimethylaminoazobenzene sulfonic acid or dimethylaminoazobenzene sodium sulfonate. An orange-yellow powder or crystalline scales. Slightly soluble in cold water; readily soluble in hot water; insoluble in alcohol. Transition interval: from pH 3.2 to 4.4. Color change: from pink to yellow.

Methyl Red (2-[4-(*Dimethylamino*)phenyl]azo]benzoic Acid Hydrochloride), $2-[4-(CH_3)_2NC_6H_4N:N]C_6H_4COOH \cdot HCl$ —**305.76**—Dark-red powder or violet crystals. Sparingly soluble in water; soluble in alcohol. Transition interval: from pH 4.2 to 6.2. Color change: from red to yellow.

Methyl Red Sodium—The sodium salt of 2-[4-(dimethylamino)phenyl]azo]benzoic acid. $2-[4-(CH_3)_2NC_6H_4N:N]C_6H_4COONa$ —**291.28**—Orange-brown powder. Freely soluble in cold water and in alcohol. Transition interval: from pH 4.2 to 6.2. Color change: from red to yellow.

Methyl Yellow (*p*-*Dimethylaminoazobenzene*), $C_{14}H_{15}N_3$ —**225.29**—Yellow crystals, melting between 114° and 117°. Insoluble in water; soluble in alcohol, in benzene, in chloroform, in ether, in dilute mineral acids, and in oils. Transition interval: from pH 2.9 to 4.0. Color change: from red to yellow.

p-Naphtholbenzein (4-[α -(4-Hydroxy-1-naphthyl)benzylidene]-1(4*H*)-naphthalenone), (4-HOC₁₀H₆) $C(C_{10}H_6-4:O)(C_6H_5)$ —**374.43**—Reddish brown powder. Insoluble in water; soluble in alcohol, in benzene, in ether, and in glacial acetic acid. Transition interval: from pH 8.8 to 10.0. Color change: from orange to green.

Neutral Red (3-Amino-7-dimethylamino-2-methylphenazine Monohydrochloride), $C_{15}H_{16}N_4 \cdot HCl$ —**288.78**—Reddish to olive-green, coarse powder. Sparingly soluble in water and in alcohol. Transition interval: from pH 6.8 to 8.0. Color change: from red to orange.

Nile Blue Hydrochloride (*Nile Blue A, as the hydrochloride*; 5-Amino-9-(diethylamino)benzo[*a*]phenoxazin-7-ium chloride), $C_{20}H_{20}ClN_3O$ —**353.85**—Slightly soluble in alcohol and in glacial acetic acid. Transition interval: from pH 9.0 to 13.0. Color change: from blue to pink.

Oracet Blue B (Solvent Blue 19)—A mixture of 1-methylamino-4-anilinoanthraquinone ($C_{21}H_{16}N_2O_2$) and 1-amino-4-anilinoanthraquinone ($C_{20}H_{14}N_2O_2$). Where used for titration in non-aqueous media, it changes from blue (basic) through purple (neutral) to pink (acidic).

Phenol Red [4,4'-(3*H*-2,1-Benzoxathiol-3-ylidene)diphenol, *S,S*-Dioxide], $C_{19}H_{14}O_5S$ —**354.38**—Crystalline powder, varying in color from bright to dark red. Very slightly soluble in water; freely soluble in solutions of alkali carbonates and hydroxides; slightly soluble in alcohol. Transition interval: from pH 6.8 to 8.2. Color change: from yellow to red.

Phenolphthalein [3,3-Bis(*p*-hydroxyphenyl)phthalide], $C_{20}H_{14}O_4$ —**318.32**—White or faintly yellowish-white, crystalline powder. Insoluble in water; soluble in alcohol. Transition interval: from pH 8.0 to 10.0. Color change: from colorless to red.

Quinaldine Red (5-Dimethylamino-2-styrylethylquinolinium iodide), $C_{21}H_{23}IN_2$ —**430.33**—Dark blue-black powder. Sparingly soluble in water; freely soluble in alcohol. Melts at about 260°, with decomposition. Transition interval: from pH 1.4 to 3.2. Color change: from colorless to red.

2-(4-Sulfophenylazo)-1,8-dihydroxy-3,6-naphthalenedisulfonic Acid, Trisodium Salt (4,5-Dihydroxy-3-(*p*-sulfophenylazo)-2,7-naphthalenedisulfonic Acid, Trisodium Salt), $C_{16}H_9N_2O_{11}S_3Na_3$ —**570.42**—Red powder. Soluble in water.

Thymol Blue (Thymolsulfonphthalein), $C_{27}H_{30}O_5S$ —**466.59**—Dark-colored, crystalline powder. Slightly soluble in water; soluble in alcohol and in dilute alkali solutions. *Acid*—Transition interval: from pH 1.2 to 2.8. Color change: from red to yellow. *Alkaline*—Transition interval: from pH 8.0 to 9.2. Color change: from yellow to blue.

Thymolphthalein, $C_{28}H_{30}O_4$ —**430.54**—White to slightly yellow, crystalline powder. Insoluble in water; soluble in alcohol and in solutions of alkali hydroxides. Transition interval: from pH 9.3 to 10.5. Color change: from colorless to blue.

Xylenol Orange, (N,N'-[3*H*-2,1-Benzoxathiol-3-ylidenebis-[(6-hydroxy-5-methyl-3,1-phenylene)methylene]]bis[N-(carboxymethyl)glycine]*S,S*-dioxide), $C_{31}H_{28}N_2Na_4O_{13}S$ —**760.58**—Orange powder. Soluble in alcohol and in water. In acid solution, it is lemon-yellow in color, and its metal complexes are intensely red. It yields a distinct endpoint where a metal such as bismuth, cadmium, lanthanum, lead, mercury, scandium, thorium, or zinc is titrated with edetate disodium.

INDICATORS AND TEST PAPERS

Indicator and test papers are strips of paper of suitable dimension and grade (see *Filter Paper, Quantitative*, in the section *Reagents*) impregnated with an indicator or a reagent that is sufficiently stable to provide a convenient form of the impregnated substance. Some test papers may be obtained from commercial sources of laboratory supplies. Those required in Pharmacopeial tests and assays may be prepared as directed in the following paragraphs, by means of the solutions specified, or to meet the tests set forth herein under the individual titles.

Treat strong, white filter paper with hydrochloric acid, and wash with water until the last washing no longer shows an acid reaction to methyl red. Then treat with ammonia TS, and wash again with water until the last washing is not alkaline to phenolphthalein.

After thorough drying, saturate the paper with the proper strength of indicator solutions, and carefully dry in still air, unless otherwise specified, by suspending it from rods of glass or other inert material in a space free from acid, alkali, and other fumes.

Cut the paper into strips of convenient size, and store the papers in well-closed containers, protected from light and moisture.

Cupric Sulfate Test Paper—Use cupric sulfate TS.

Lead Acetate Test Paper—Usually about 6 × 80 mm in size. Use lead acetate TS, and dry the paper at 100°, avoiding contact with metal.

Litmus Paper, Blue—Usually about 6 × 50 mm in size. It meets the requirements of the following tests.

Phosphate (Reagent test)—Cut 5 strips into small pieces, mix with 500 mg of magnesium nitrate in a porcelain crucible, and ignite. To the residue add 5 mL of nitric acid, and evaporate to dryness: the residue shows not more than 0.02 mg of PO_4 .

Residue on ignition—Ignite carefully 10 strips of the paper to constant weight: the weight of the residue corresponds to not more than 0.4 mg per strip of about 3 square cm.

Rosin acids—Immerse a strip of the blue paper in a solution of 100 mg of silver nitrate in 50 mL of water: the color of the paper does not change in 30 seconds.

Sensitiveness—Drop a 10- to 12-mm strip into 100 mL of 0.0005 *N* acid contained in a beaker, and stir continuously: the color of the paper is changed within 45 seconds. The 0.0005 *N* acid is prepared by diluting 1 mL of 0.1 *N* hydrochloric acid with freshly boiled and cooled purified water to 200 mL.

Litmus Paper, Red—Usually about 6 × 50 mm in size. Red litmus paper meets the requirements of the tests for *Phosphate*, *Residue on ignition*, and *Rosin acids*, under *Litmus Paper, Blue*.

Sensitiveness—Drop a 10- to 12-mm strip into 100 mL of 0.0005 *N* sodium hydroxide contained in a beaker, and stir continuously: the color of the paper changes within 30 seconds. The 0.0005 *N* sodium hydroxide is prepared by diluting 1 mL of 0.1 *N* sodium hydroxide with freshly boiled and cooled purified water to 200 mL.

Mercuric Bromide Test Paper—Place a 50 mg/mL solution of mercuric bromide in dehydrated alcohol in a dish, and immerse in it pieces of white filter paper weighing 80 g/m² (speed of filtration = filtration time expressed in s for 100 mL of water at 20° with a filter surface of 10 cm² and a constant pressure of 6.7 kPa; 40–60 s), each measuring 1.5 cm by 20 cm and folded in the middle. Allow the excess of liquid to drain, and allow the paper to dry, protected from light, suspended over a nonmetallic thread. Discard 1 cm from each end of each strip, and cut the remainder into 1.5-cm squares or discs of 1.5-cm diameter. Store in a glass-stoppered container wrapped with black paper.

Methyl Green-Iodomercurate Paper—Immerse thin strips of suitable filter paper in a 40 g per L solution of methyl green, and allow to air-dry. Immerse the strips for 1 hour in a solution containing 140 g per L of potassium iodide and 200 g per L of mercuric iodide. Wash with water until the washings are practically colorless, and allow to air-dry. Store protected from light, and use within 48 hours.

Methyl Yellow Paper—Use a 1 in 2000 solution of methyl yellow in alcohol.

pH Indicator Paper, Short-Range—Use a suitable grade.

Phenolphthalein Paper—Use a 1 in 1000 solution of phenolphthalein in diluted alcohol.

Starch Iodate Paper—Use a mixture of equal volumes of starch TS and potassium iodate solution (1 in 20).

Starch Iodide Paper—Use a solution of 500 mg of potassium iodide in 100 mL of freshly prepared starch TS.

Thiazole Yellow Paper—Use a 1 in 2000 solution of thiazole yellow in water.

Turmeric Paper—Use a solution prepared as follows: Macerate 20 g of powdered turmeric, the dried root of *Curcuma longa* Linné (Fam. Zingiberaceae), with four 100-mL portions of cold water, decanting the clear liquid portion each time and discarding it. Dry the residue at a temperature not over 100°. Macerate with 100 mL of alcohol for several days, and filter.

Sensitiveness—Dip a strip of the paper, of about 1.5-cm length, in a solution of 1.0 mg of boric acid in 5 mL of water, previously mixed with 1 mL of hydrochloric acid. After 1 minute remove the paper from the liquid, and allow it to dry: the yellow color changes to brown. Then moisten the paper with ammonia TS: the color of the paper changes to greenish black.

Solutions

BUFFER SOLUTIONS

The successful completion of many Pharmacopeial tests and assays requires adjustment to or maintenance of a specified pH by the addition of buffer solutions. In pH measurements, standard buffer solutions are required for reference purposes. For convenience, the preparation of these solutions is in some instances described in the sections in which their use is specified; i.e., five separate phosphate buffers are described under *Antibiotics—Microbial Assays* (81), and several miscellaneous single-purpose solutions are described in the individual monographs.

A solution is said to be buffered if it resists changes in the activity of an ion on the addition of substances that are expected to change the activity of that ion. Buffers are substances or combinations of substances that impart this resistance to a solution. Buffered solutions are systems in which the ion is in equilibrium with substances capable of removing or releasing the ion.

Buffer capacity refers to the amount of material that may be added to a solution without causing a significant change in ion activity. It is defined as the ratio of acid or base added (in gram-equivalents per liter) to the change in pH (in pH units). The capacity of a buffered solution is adjusted to the conditions of use, usually by adjustment of the concentrations of buffer substances.

Buffers are used to establish and maintain an ion activity within narrow limits. The most common systems are used (a) to establish hydrogen-ion activity for the calibration of pH meters, (b) in the preparation of dosage forms that approach isotonicity, (c) in analytical procedures, and (d) to maintain stability of various dosage forms. Buffers used in physiological systems are carefully chosen so as not to interfere with pharmacological activity of the medicament or normal function of the organism. It is essential that buffers used in chemical analysis be compatible with the substance determined and the reagents used.

Standard Buffer Solutions—Standard solutions of definite pH are readily available in buffer solutions prepared from the appropriate reagents. In addition, buffer solutions, buffer

tablets, and buffer solids may be obtained from commercial sources in convenient prepackaged form. Such preparations are available for the entire working range in pharmaceutical analysis, but are not recommended for pH meter standardization (see *pH* (791)).

The required reagents are described in the section, *Reagents*. Previously dry the crystalline reagents, except the boric acid and sodium acetate trihydrate, at 110° to 120° for 1 hour.

[NOTE—Where water is specified for solution or dilution of test substances in pH determinations, use carbon dioxide-free water.]

Store the prepared solutions in chemically resistant, tight containers such as Type I glass bottles. Use the solutions within 3 months.

Standard Buffer Solutions for various ranges between pH 1.2 and 10.0 may be prepared by appropriate combinations of the solutions described herein, used in the proportions shown in the accompanying table. The volumes shown in the table are for 200 mL of buffer solution, except that the volumes shown for *Acetate Buffer* are used to prepare 1000 mL of buffer solution.

1. *Hydrochloric Acid, 0.2 M*, and *Sodium Hydroxide, 0.2 M*—Prepare and standardize as directed under *Volumetric Solutions*.
2. *Potassium Biphthalate, 0.2 M*—Dissolve 40.85 g of potassium biphthalate [$\text{KHC}_8\text{H}_4(\text{COO})_2$] in water, and dilute with water to 1000 mL.
3. *Potassium Phosphate, Monobasic 0.2 M*—Dissolve 27.22 g of monobasic potassium phosphate (KH_2PO_4) in water, and dilute with water to 1000 mL.
4. *Boric Acid and Potassium Chloride, 0.2 M*—Dissolve 12.37 g of boric acid (H_3BO_3) and 14.91 g of potassium chloride (KCl) in water, and dilute with water to 1000 mL.
5. *Potassium Chloride, 0.2 M*—Dissolve 14.91 g of potassium chloride (KCl) in water, and dilute with water to 1000 mL.
6. *Acetic Acid, 2 N*—Prepare and standardize as directed under *Volumetric Solutions*.

Composition of Standard Buffer Solutions											
<i>Hydrochloric Acid Buffer</i>											
Place 50 mL of the potassium chloride solution in a 200-mL volumetric flask, add the specified volume of the hydrochloric acid solution, then add water to volume.											
pH	1.2	1.3	1.4	1.5	1.6	1.7	1.8	1.9	2.0	2.1	2.2
0.2 M HCl, mL	85.0	67.2	53.2	41.4	32.4	26.0	20.4	16.2	13.0	10.2	7.8

<i>Acid Phthalate Buffer</i>											
Place 50 mL of the potassium biphthalate solution in a 200-mL volumetric flask, add the specified volume of the hydrochloric acid solution, then add water to volume.											
pH	2.2	2.4	2.6	2.8	3.0	3.2	3.4	3.6	3.8	4.0	
0.2 M HCl, mL	49.5	42.2	35.4	28.9	22.3	15.7	10.4	6.3	2.9	0.1	

<i>Neutralized Phthalate Buffer</i>											
Place 50 mL of the potassium biphthalate solution in a 200-mL volumetric flask, add the specified volume of the sodium hydroxide solution, then add water to volume.											
pH		4.2	4.4	4.6	4.8	5.0	5.2	5.4	5.6	5.8	
0.2 M NaOH, mL		3.0	6.6	11.1	16.5	22.6	28.8	34.1	38.8	42.3	

Phosphate Buffer												
Place 50 mL of the monobasic potassium phosphate solution in a 200-mL volumetric flask, add the specified volume of the sodium hydroxide solution, then add water to volume.												
pH	5.8	6.0	6.2	6.4	6.6	6.8	7.0	7.2	7.4	7.6	7.8	8.0
0.2 M NaOH, mL	3.6	5.6	8.1	11.6	16.4	22.4	29.1	34.7	39.1	42.4	44.5	46.1

Alkaline Borate Buffer												
Place 50 mL of the boric acid and potassium chloride solution in a 200-mL volumetric flask, add the specified volume of the sodium hydroxide solution, then add water to volume.												
pH	8.0	8.2	8.4	8.6	8.8	9.0	9.2	9.4	9.6	9.8	10.0	
0.2 M NaOH, mL	3.9	6.0	8.6	11.8	15.8	20.8	26.4	32.1	36.9	40.6	43.7	

Acetate Buffer											
Place the specified amount of sodium acetate $\text{NaC}_2\text{H}_3\text{O}_2 \cdot 3\text{H}_2\text{O}$ in a 1000-mL volumetric flask, add the specified volume of the acetic acid solution, then add water to volume, and mix.											
pH	4.1	4.3	4.5	4.7	4.9	5.1	5.2	5.3	5.4	5.5	
pH (measured)	4.10	4.29	4.51	4.70	4.90	5.11	5.18	5.30	5.40	5.48	
$\text{NaC}_2\text{H}_3\text{O}_2 \cdot 3\text{H}_2\text{O}$, g	1.5	1.99	2.99	3.59	4.34	5.08	5.23	5.61	5.76	5.98	
2 N CH_3COOH , mL	19.5	17.7	14.0	11.8	9.1	6.3	5.8	4.4	3.8	3.0	

COLORIMETRIC SOLUTIONS (CS)

(For the Preparation of Matching Fluids, see *Color and Achromicity* (631).)

These solutions are used in the preparation of the colorimetric standards for certain drugs, and for the carbonization tests with sulfuric acid that are specified in several monographs. Store the solutions in suitably resistant, tight containers.

Comparison of colors as directed in the Pharmacopeial tests preferably is made in matched color-comparison tubes or in a suitable colorimeter under conditions that ensure that the colorimetric reference solution and that of the specimen under test are treated alike in all respects. The comparison of colors is best made in layers of equal depth, and viewed transversely against a white background (see also *Visual Comparison under Spectrophotometry and Light-Scattering* (851)). It is particularly important that the solutions be compared at the same temperature, preferably 25°.

Cobaltous Chloride CS—Dissolve about 65 g of cobaltous chloride ($\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$) in enough of a mixture of 25 mL of hydrochloric acid and 975 mL of water to make 1000 mL. Pipet 5 mL of this solution into a 250-mL iodine flask, add 5 mL of hydrogen peroxide TS and 15 mL of sodium hydroxide solution (1 in 5), boil for 10 minutes, cool, and add 2 g of potassium iodide and 20 mL of dilute sulfuric acid (1 in 4). When the precipitate has dissolved, titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the indicator. Perform a blank determination with the same quantities of the same reagents, and make any necessary correction. Each mL of 0.1 N sodium thiosulfate is equivalent to 23.79 mg of $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$. Adjust the final volume of the solution by the addition of enough of the mixture of hydrochloric acid and water so that each mL contains 59.5 mg of $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$.

Cupric Sulfate CS—Dissolve about 65 g of cupric sulfate ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$) in enough of a mixture of 25 mL of hydrochloric acid and 975 mL of water to make 1000 mL. Pipet 10 mL of this solution into a 250-mL iodine flask, add 40 mL of water, 4 mL of acetic acid, 3 g of potassium iodide, and 5 mL of hydrochloric acid, and titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the indicator. Perform a blank determination with the same quantities of the same reagents, and make any necessary correction. Each mL of 0.1 N sodium thiosulfate is equivalent to 24.97 mg of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$. Adjust the final volume of the solution by the addition of enough of the mixture of hydrochloric acid and water so that each mL contains 62.4 mg of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$.

Ferric Chloride CS—Dissolve about 55 g of ferric chloride ($\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$) in enough of a mixture of 25 mL of hydrochloric acid and 975 mL of water to make 1000 mL. Pipet 10 mL of this solution into a 250-mL iodine flask, add 15 mL of water, 3 g of potassium iodide, and 5 mL of hydrochloric acid, and allow the mixture to stand for 15 minutes. Dilute with 100 mL of water, and titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the indicator. Perform a blank determination with the same quantities of the same reagents, and make any necessary correction. Each mL of 0.1 N sodium thiosulfate is equivalent to 27.03 mg of $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$. Adjust the final volume of the solution by the addition of enough of the mixture of hydrochloric acid and water so that each mL contains 45.0 mg of $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$.

INDICATOR SOLUTIONS

See *TEST SOLUTIONS*.

TEST SOLUTIONS (TS)

Certain of the following test solutions are intended for use as acid-base indicators in volumetric analyses. Such solutions should be so adjusted that when 0.15 mL of the indicator solution is added to 25 mL of carbon dioxide-free water, 0.25 mL of 0.02 N acid or alkali, respectively, will produce the characteristic color change. Similar solutions are intended for use in pH measurement. Where no special directions for their preparation are given, the same solution is suitable for both purposes.

Where it is directed that a volumetric solution be used as the test solution, standardization of the solution used as TS is not required.

In general, the directive to prepare a solution "fresh" indicates that the solution is of limited stability and must be prepared on the day of use.

For the preparation of Test Solutions, use reagents of the quality described under *Reagents*.

Acetaldehyde TS—Mix 4 mL of acetaldehyde, 3 mL of alcohol, and 1 mL of water. Prepare this solution fresh.

Acetate Buffer TS—Dissolve 320 g of ammonium acetate in 500 mL of water, add 5 mL of glacial acetic acid, dilute with water to 1000.0 mL, and mix. This solution has a pH between 5.9 and 6.0.

Acetic Acid, Glacial, TS—Determine the water content of a specimen of glacial acetic acid by the *Titrimetric Method* (see *Water Determination* (921)). If the acid contains more than 0.4% of water, add a few mL of acetic anhydride, mix, allow to stand overnight, and again determine the water

content. If the acid contains less than 0.02% of water, add sufficient water to make the final concentration between 0.02% and 0.4%, mix, allow to stand overnight, and again determine the water content. Repeat the adjustment with acetic anhydride or water, as necessary, until the resulting solution shows a water content of not more than 0.4%.

Acetic Acid, Strong, TS—Add 300.0 mL of glacial acetic acid, and dilute with water to 1000 mL. This solution contains about 30% (v/v) of CH_3COOH and has a concentration of about 5 N.

Acetic Acid–Ammonium Acetate Buffer TS—Dissolve 77.1 g of ammonium acetate in water, add 57 mL of glacial acetic acid, and dilute with water to 1000 mL.

Acetone, Buffered, TS—Dissolve 8.15 g of sodium acetate and 42 g of sodium chloride in about 100 mL of water, and add 68 mL of 0.1 N hydrochloric acid and 150 mL of acetone. Mix, and dilute with water to 500 mL.

Acid Ferric Chloride TS—Mix 60 mL of glacial acetic acid with 5 mL of sulfuric acid, add 1 mL of ferric chloride TS, mix, and cool.

Acid Ferrous Sulfate TS—See *Ferrous Sulfate, Acid, TS*.

Acid Stannous Chloride TS—See *Stannous Chloride, Acid, TS*.

Change to read:

Acid Stannous Chloride TS, Stronger—See **Stannous Chloride, Acid, Stronger, TS**. • (ERR 1-Jul-2012)

Albumen TS—Carefully separate the white from the yolk of a strictly fresh hen's egg. Shake the white with 100 mL of water until mixed and all but the chalaza has undergone solution; then filter. Prepare the solution fresh.

Alcohol–Phenol TS—Dissolve 780 mg of phenol in alcohol to make 100 mL.

Alcoholic TS—It contains 95 parts of specially denaturated alcohol 3A with 5 parts of isopropyl alcohol. The final concentrations are approximately 90% alcohol, 5% methanol, and 5% isopropanol.

[NOTE—A suitable grade is available as Reagent alcohol, catalog number R8382, available at www.sigma-aldrich.com.]

Alcoholic Ammonia TS—See *Ammonia TS, Alcoholic*.

Alcoholic Mercuric Bromide TS—See *Mercuric Bromide TS, Alcoholic*.

Alcoholic Potassium Hydroxide TS—See *Potassium Hydroxide TS, Alcoholic*.

Alkaline Cupric Citrate TS—See *Cupric Citrate TS, Alkaline*.

Alkaline Cupric Citrate TS 2—See *Cupric Citrate TS 2, Alkaline*.

Alkaline Cupric Iodide TS—See *Cupric Iodide TS, Alkaline*.

Alkaline Cupric Tartrate TS (Fehling's Solution)—See *Cupric Tartrate TS, Alkaline*.

Alkaline Mercuric–Potassium Iodide TS—See *Mercuric–Potassium Iodide TS, Alkaline*.

Alkaline Picrate TS—See *Picrate TS, Alkaline*.

Alkaline Sodium Hydrosulfite TS—See *Sodium Hydrosulfite TS, Alkaline*.

Amaranth TS—Dissolve 20 mg of amaranth in 10 mL of water.

Aminonaphtholsulfonic Acid TS—Accurately weigh 5 g of sodium sulfite, 94.3 g of sodium bisulfite, and 700 mg of 1,2,4-aminonaphtholsulfonic acid, and mix. Prepare aminonaphtholsulfonic acid TS fresh on the day of use by dissolving 1.5 g of the dry mixture in 10 mL of water.

Ammonia TS—It contains between 9.5% and 10.5% of NH_3 . Prepare by diluting 350 mL of *Ammonia Water, Stronger* (see in the section, *Reagents*) with water to make 1000 mL.

Ammonia TS 2—Prepare by diluting 13.5 mL of *Ammonia Water, Stronger* (see *Reagent Specifications* in the section *Reagents*) with water to make 100 mL.

Ammonia TS, Alcoholic—A solution of ammonia gas in alcohol. Clear, colorless liquid having a strong odor of am-

monia. Specific gravity: about 0.80. It contains between 9% and 11% of NH_3 . Store it in alkali-resistant containers, in a cold place.

Ammonia TS, Stronger—Use *Ammonia Water, Stronger* (see in the section *Reagents*).

Ammonia–Ammonium Chloride Buffer TS—Dissolve 67.5 g of ammonium chloride in water, add 570 mL of ammonium hydroxide, and dilute with water to 1000 mL.

Ammonia–Cyanide TS—Dissolve 2 g of potassium cyanide in 15 mL of ammonium hydroxide, and dilute with water to 100 mL.

Ammoniacal Potassium Ferricyanide TS—Dissolve 2 g of potassium ferricyanide in 75 mL of water, add 25 mL of ammonium hydroxide, and mix.

Ammoniated Cupric Oxide TS—See *Cupric Oxide, Ammoniated, TS*.

Ammonium Acetate TS—Dissolve 10 g of ammonium acetate in water to make 100 mL.

Ammonium Carbonate TS—Dissolve 20 g of ammonium carbonate and 20 mL of ammonia TS in water to make 100 mL.

Ammonium Carbonate TS 2—Prepare a 158-mg/mL solution of ammonium carbonate in water.

Ammonium Chloride TS—Dissolve 10.5 g of ammonium chloride in water to make 100 mL.

Ammonium Chloride–Ammonium Hydroxide TS—Mix equal volumes of water and ammonium hydroxide, and saturate with ammonium chloride.

Ammonium Molybdate TS—Dissolve 6.5 g of finely powdered molybdic acid in a mixture of 14 mL of water and 14.5 mL of ammonium hydroxide. Cool the solution, and add it slowly, with stirring, to a well-cooled mixture of 32 mL of nitric acid and 40 mL of water. Allow to stand for 48 hours, and filter through a fine-porosity, sintered-glass crucible. This solution deteriorates upon standing and is unsuitable for use if, upon the addition of 2 mL of dibasic sodium phosphate TS to 5 mL of the solution, an abundant yellow precipitate does not form at once or after slight warming. Store it in the dark. If a precipitate forms during storage, use only the clear supernatant.

Ammonium Oxalate TS—Dissolve 3.5 g of ammonium oxalate in water to make 100 mL.

Ammonium Phosphate, Dibasic, TS (Ammonium Phosphate TS)—Dissolve 13 g of dibasic ammonium phosphate in water to make 100 mL.

Ammonium Polysulfide TS—Yellow liquid, made by saturating ammonium sulfide TS with sulfur.

Ammonium Pyrrolidinedithiocarbamate, Saturated, TS—Add about 10 g of ammonium pyrrolidinedithiocarbamate to a 1000-mL volumetric flask, and dilute with water to volume.

Ammonium Reineckate TS—Shake about 500 mg of ammonium reineckate with 20 mL of water frequently during 1 hour, and filter. Use within 2 days.

Ammonium Sulfide TS—Use ACS reagent-grade Ammonium Sulfide Solution.

Ammonium Thiocyanate TS—Dissolve 8 g of ammonium thiocyanate in water to make 100 mL.

Ammonium Vanadate TS—Dissolve 2.5 g of ammonium vanadate in 500 mL of boiling water, cool, and add 20 mL of nitric acid. Mix, cool, and add water to make 1 L. Store in polyethylene containers.

Anthrone TS—Within 12 hours of use, rapidly dissolve 35 mg of anthrone in a hot mixture of 35 mL of water and 65 mL of sulfuric acid. Immediately cool in an ice bath to room temperature, and filter through glass wool. Allow the solution to stand at room temperature for 30 minutes before use.

Antimony Trichloride TS—Dissolve 20 g of antimony trichloride in chloroform to make 100 mL. Filter if necessary.

Barium Chloride TS—Dissolve 12 g of barium chloride in water to make 100 mL.

Barium Hydroxide TS—A saturated solution of barium hydroxide in recently boiled water. Prepare the solution fresh.

Barium Nitrate TS—Dissolve 6.5 g of barium nitrate in water to make 100 mL.

Betanaphthol TS—See *2-Naphthol TS*.

Biuret Reagent TS—Dissolve 1.5 g of cupric sulfate and 6.0 g of potassium sodium tartrate in 500 mL of water in a 1000-mL volumetric flask. Add 300 mL of carbonate-free sodium hydroxide solution (1 in 10), dilute with carbonate-free sodium hydroxide solution (1 in 10) to 1000 mL, and mix.

Blue Tetrazolium TS—Dissolve 500 mg of blue tetrazolium in alcohol to make 100 mL.

Brilliant Blue G TS—Transfer 25 mg of brilliant blue G to a 100-mL volumetric flask, add 12.5 mL of alcohol and 25 mL of phosphoric acid, dilute with water to volume, and mix.

Bromine TS (Bromine Water)—A saturated solution of bromine, prepared by agitating 2 to 3 mL of bromine with 100 mL of cold water in a glass-stoppered bottle, the stopper of which should be lubricated with petrolatum. Store it in a cold place, protected from light.

Bromine-Sodium Acetate TS—Dissolve 100 g of sodium acetate in 1000 mL of glacial acetic acid, add 50 mL of bromine, and mix.

p-Bromoaniline TS—Add 8 g of *p*-bromoaniline to a mixture of 380 mL of thiourea-saturated glacial acetic acid, 10 mL of sodium chloride solution (1 in 5), 5 mL of oxalic acid solution (1 in 20), and 5 mL of dibasic sodium phosphate solution (1 in 10) in a low-actinic glass bottle. Mix, and allow to stand overnight before using. Protect from light, and use within 7 days.

Bromocresol Blue TS—Use *Bromocresol Green TS*.

Bromocresol Green TS—Dissolve 50 mg of bromocresol green in 100 mL of alcohol, and filter if necessary.

Bromocresol Green-Methyl Red TS—Dissolve 0.15 g of bromocresol green and 0.1 g of methyl red in 180 mL of alcohol, and dilute with water to 200 mL.

Bromocresol Purple TS—Dissolve 250 mg of bromocresol purple in 20 mL of 0.05 N sodium hydroxide, and dilute with water to 250 mL.

Bromophenol Blue TS—Dissolve 100 mg of bromophenol blue in 100 mL of diluted alcohol, and filter if necessary.

Bromothymol Blue TS—Dissolve 100 mg of bromothymol blue in 100 mL of diluted alcohol, and filter if necessary.

Buffered Acetone TS—See *Acetone, Buffered, TS*.

Calcium Chloride TS—Dissolve 7.5 g of calcium chloride in water to make 100 mL.

Calcium Hydroxide TS—Use *Calcium Hydroxide Topical Solution* (USP monograph).

Calcium Sulfate TS—A saturated solution of calcium sulfate in water.

Ceric Ammonium Nitrate TS—Dissolve 6.25 g of ceric ammonium nitrate in 10 mL of 0.25 N nitric acid. Use within 3 days.

Chloral Hydrate TS—Dissolve 50 g of chloral hydrate in a mixture of 15 mL of water and 10 mL of glycerin.

Chlorine TS (Chlorine Water)—A saturated solution of chlorine in water. Place the solution in small, completely filled, light-resistant containers. Chlorine TS, even when kept from light and air, is apt to deteriorate. Store it in a cold, dark place. For full strength, prepare this solution fresh.

Chromotropic Acid TS—Dissolve 50 mg of chromotropic acid or its disodium salt in 100 mL of 75% sulfuric acid, which may be made by cautiously adding 75 mL of sulfuric acid to 33.3 mL of water.

Cobalt-Uranyl Acetate TS—Dissolve, with warming, 40 g of uranyl acetate in a mixture of 30 g of glacial acetic acid and sufficient water to make 500 mL. Similarly, prepare a solution containing 200 g of cobaltous acetate in a mixture of 30 g of glacial acetic acid and sufficient water to make 500 mL. Mix the two solutions while still warm, and cool to 20°. Maintain the temperature at 20° for about 2 hours to separate the excess salts from solution, and then pass through a dry filter.

Cobaltous Chloride TS—Dissolve 2 g of cobaltous chloride in 1 mL of hydrochloric acid and sufficient water to make 100 mL.

Congo Red TS—Dissolve 500 mg of congo red in a mixture of 10 mL of alcohol and 90 mL of water.

m-Cresol Purple TS—Dissolve 0.10 g of metacresol purple in 13 mL of 0.01 N sodium hydroxide, dilute with water to 100 mL, and mix.

Cresol Red TS—Triturate 100 mg of cresol red in a mortar with 26.2 mL of 0.01 N sodium hydroxide until solution is complete, then dilute the solution with water to 250 mL.

Cresol Red-Thymol Blue TS—Add 15 mL of thymol blue TS to 5 mL of cresol red TS, and mix.

Crystal Violet TS—Dissolve 100 mg of crystal violet in 10 mL of glacial acetic acid.

Cupric Acetate TS—Dissolve 100 mg of cupric acetate in about 5 mL of water to which a few drops of acetic acid have been added. Dilute to 100 mL, and filter, if necessary.

Cupric Acetate TS, Stronger (Barfoed's Reagent)—Dissolve 13.3 g of cupric acetate in a mixture of 195 mL of water and 5 mL of acetic acid.

Cupric-Ammonium Sulfate TS—To cupric sulfate TS add ammonia TS, dropwise, until the precipitate initially formed is nearly but not completely dissolved. Allow to settle, and decant the clear solution. Prepare this solution fresh.

Cupric Citrate TS—Dissolve 25 g of cupric sulfate, 50 g of citric acid, and 144 g of anhydrous sodium carbonate in water, and dilute with water to 1000 mL.

Cupric Citrate TS, Alkaline—With the aid of heat, dissolve 173 g of dihydrated sodium citrate and 117 g of monohydrated sodium carbonate in about 700 mL of water, and filter through paper, if necessary, to obtain a clear solution. In a separate container dissolve 17.3 g of cupric sulfate in about 100 mL of water, and slowly add this solution, with constant stirring, to the first solution. Cool the mixture, add water to make 1000 mL, and mix.

Cupric Citrate TS 2, Alkaline—With the aid of heat, dissolve about 173 g of sodium citrate dihydrate and 117 g of sodium carbonate monohydrate in about 700 mL of water, and filter. In a second flask, dissolve about 27.06 g of cupric sulfate ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$) in about 100 mL of water. Slowly combine the two solutions while stirring, and dilute with water to 1000 mL.

Cupric Iodide TS, Alkaline—Dissolve 7.5 g of cupric sulfate ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$) in about 100 mL of water. In a separate container dissolve 25 g of anhydrous sodium carbonate, 20 g of sodium bicarbonate, and 25 g of potassium sodium tartrate in about 600 mL of water. With constant stirring, add the cupric sulfate solution to the bottom of the alkaline tartrate solution by means of a funnel that touches the bottom of the container. Add 1.5 g of potassium iodide, 200 g of anhydrous sodium sulfate, 50 to 150 mL of 0.02 M potassium iodate, and sufficient water to make 1000 mL.

Cupric Oxide, Ammoniated, TS (Schweitzer's Reagent)—Dissolve 10 g of cupric sulfate in 100 mL of water, add sufficient sodium hydroxide solution (1 in 5) to precipitate the copper hydroxide, collect the latter on a filter, and wash free from sulfate with cold water. Dissolve the precipitate, which must be kept wet during the entire process, in the minimum quantity of ammonia TS necessary for complete solution.

Cupric Sulfate TS—Dissolve 12.5 g of cupric sulfate in water to make 100 mL.

Cupric Tartrate TS, Alkaline (Fehling's Solution)—

The Copper Solution (A)—Dissolve 34.66 g of carefully selected, small crystals of cupric sulfate, showing no trace of efflorescence of adhering moisture, in water to make 500 mL. Store this solution in small, tight containers.

The Alkaline Tartrate Solution (B)—Dissolve 173 g of crystallized potassium sodium tartrate and 50 g of sodium hydroxide in water to make 500 mL. Store this solution in small, alkali-resistant containers.

For use, mix exactly equal volumes of *Solutions A and B* at the time required.

Delafield's Hematoxylin TS—Prepare 400 mL of a saturated solution of ammonium alum (*Solution A*). Dissolve 4 g of hematoxylin in 25 mL of alcohol, mix it with *Solution A*, and allow it to stand for 4 days in a flask closed with a pledget of purified cotton and exposed to light and air (*Solution B*). Then filter *Solution B*, and add to it a *Solution C* consisting of a mixture of 100 mL of glycerin and 100 mL of methanol. Mix, and allow the mixture to stand in a warm place, exposed to light, for 6 weeks until it becomes dark-colored. Store in tightly stoppered bottles.

For use in staining endocrine tissue, dilute this test solution with an equal volume of water.

Denaturated Alcoholic TS—A specially denaturated alcohol containing either rubber hydrocarbon solvent of heptane or toluene. [NOTE—A suitable grade is available from www.lyondell.com or from www.sasol.com, as Ethanol SDA 2B HEP 200, or Ethanol SDA 2B TOL 200, or Ethanol SDA 2B TOL 190, or Alcohol SDA 2B-2.]

Denigès' Reagent—See *Mercuric Sulfate TS*.

Diazobenzenesulfonic Acid TS—Place in a beaker 1.57 g of sulfanilic acid, previously dried at 105° for 3 hours, add 80 mL of water and 10 mL of diluted hydrochloric acid, and warm on a steam bath until dissolved. Cool to 15° (some of the sulfanilic acid may separate but will dissolve later), and add slowly, with constant stirring, 6.5 mL of sodium nitrite solution (1 in 10). Then dilute with water to 100 mL.

Dichlorofluorescein TS—Dissolve 100 mg of dichlorofluorescein in 60 mL of alcohol, add 2.5 mL of 0.1 N sodium hydroxide, mix, and dilute with water to 100 mL.

2,7-Dihydroxynaphthalene TS—Dissolve 100 mg of 2,7-dihydroxynaphthalene in 1000 mL of sulfuric acid, and allow the solution to stand until the yellow color disappears. If the solution is very dark, discard it and prepare a new solution from a different supply of sulfuric acid. This solution is stable for approximately 1 month if stored in a dark bottle.

Diiodofluorescein TS—Dissolve 500 mg of diiodofluorescein in a mixture of 75 mL of alcohol and 30 mL of water.

Diluted Lead Subacetate TS—See *Lead Subacetate TS, Diluted*.

p-Dimethylaminobenzaldehyde TS—Dissolve 125 mg of p-dimethylaminobenzaldehyde in a cooled mixture of 65 mL of sulfuric acid and 35 mL of water, and add 0.05 mL of ferric chloride TS. Use within 7 days.

Dinitrophenylhydrazine TS—Carefully mix 10 mL of water and 10 mL of sulfuric acid, and cool. To the mixture, contained in a glass-stoppered flask, add 2 g of 2,4-dinitrophenylhydrazine, and shake until dissolved. To the solution add 35 mL of water, mix, cool, and filter.

Diphenylamine TS—Dissolve 1.0 g of diphenylamine in 100 mL of sulfuric acid. The solution should be colorless.

Diphenylcarbazone TS—Dissolve 1 g of crystalline diphenylcarbazone in 75 mL of alcohol, then add alcohol to make 100 mL. Store in a brown bottle.

Dithizone TS—Dissolve 25.6 mg of dithizone in 100 mL of alcohol. Store in a cold place, and use within 2 months.

Dragendorff's TS—Mix 850 mg of bismuth subnitrate with 40 mL of water and 10 mL of glacial acetic acid (*Solution A*). Dissolve 8 g of potassium iodide in 20 mL of water (*Solution B*). Mix equal portions of *Solution A* and *Solution B* to obtain a stock solution, which can be stored for several months in a dark bottle. Mix 10 mL of the stock solution with 20 mL of glacial acetic acid, and dilute with water to make 100 mL.

Edetate Disodium TS—Dissolve 1 g of edetate disodium in 950 mL of water, add 50 mL of alcohol, and mix.

Eosin Y TS (adsorption indicator)—Dissolve 50 mg of eosin Y in 10 mL of water.

Eriochrome Black TS—Dissolve 200 mg of eriochrome black T and 2 g of hydroxylamine hydrochloride in methanol to make 50 mL.

Eriochrome Cyanine TS—Dissolve 750 mg of eriochrome cyanine R in 200 mL of water, add 25 g of sodium chloride, 25 g of ammonium nitrate, and 2 mL of nitric acid, and dilute with water to 1000 mL.

Fehling's Solution—See *Cupric Tartrate TS, Alkaline*.

Ferric Ammonium Sulfate TS—Dissolve 8 g of ferric ammonium sulfate in water to make 100 mL.

Ferric Chloride TS—Dissolve 9 g of ferric chloride in water to make 100 mL.

Ferrioin TS—Dissolve 0.7 g of ferrous sulfate and 1.76 g of o-phenanthroline monohydrochloride monohydrate in water, and dilute with water to 100 mL.

Ferrous Sulfate TS—Dissolve 8 g of clear crystals of ferrous sulfate in about 100 mL of recently boiled and thoroughly cooled water. Prepare this solution fresh.

Ferrous Sulfate, Acid, TS—Dissolve 7 g of ferrous sulfate crystals in 90 mL of recently boiled and thoroughly cooled water, and add sulfuric acid to make 100 mL. Prepare this solution immediately prior to use.

Folin-Ciocalteu Phenol TS—Into a 1500-mL flask introduce 100 g of sodium tungstate, 25 g of sodium molybdate, 700 mL of water, 50 mL of phosphoric acid, and 100 mL of hydrochloric acid. Gently reflux the mixture for about 10 hours, and add 150 g of lithium sulfate, 50 mL of water, and a few drops of bromine. Boil the mixture, without the condenser, for about 15 minutes, or until the excess bromine is expelled. Cool, dilute with water to 1 L, and filter: the filtrate has no greenish tint. Before use, dilute 1 part of the filtrate with 1 part of water. When used for protein determination (i.e., Lowry assay), this reagent must be further diluted (1:5) with water. See *Method 2* in *Total Protein Assay* under *Biotechnology-Derived Articles—Total Protein Assay* (1057).

Formaldehyde TS—Use *Formaldehyde Solution* (see in the section *Reagents*).

Fuchsin-Pyrogallol TS—Dissolve 100 mg of basic fuchsin in 50 mL of water that previously has been boiled for 15 minutes and allowed to cool slightly. Cool, add 2 mL of a saturated solution of sodium bisulfite, mix, and allow to stand for not less than 3 hours. Add 0.9 mL of hydrochloric acid, mix, and allow to stand overnight. Add 100 mg of pyrogallol, shake until solution is effected, and dilute with water to 100 mL. Store in an amber-colored glass bottle in a refrigerator.

Fuchsin-Sulfurous Acid TS—Dissolve 200 mg of basic fuchsin in 120 mL of hot water, and allow the solution to cool. Add a solution of 2 g of anhydrous sodium sulfite in 20 mL of water, then add 2 mL of hydrochloric acid. Dilute the solution with water to 200 mL, and allow to stand for at least 1 hour. Prepare this solution fresh.

Gastric Fluid, Simulated, TS—Dissolve 2.0 g of sodium chloride and 3.2 g of purified pepsin, that is derived from porcine stomach mucosa, with an activity of 800 to 2500 units per mg of protein, in 7.0 mL of hydrochloric acid and sufficient water to make 1000 mL. [NOTE—Pepsin activity is described in the *Food Chemicals Codex* specifications under *General Tests and Assays*.] This test solution has a pH of about 1.2.

Gelatin TS (for the assay of *Corticotropin Injection*)—Dissolve 340 g of acid-treated precursor gelatin (Type A) in water to make 1000 mL. Heat the solution in an autoclave at 115° for 30 minutes after the exhaust line temperature has reached 115°. Cool the solution, and add 10 g of phenol and 1000 mL of water. Store in tight containers in a refrigerator.

Glacial Acetic Acid TS—See *Acetic Acid, Glacial, TS*.

Glucose Oxidase-Chromogen TS—A solution containing, in each mL, 0.5 μ mol of 4-aminoantipyrine, 22.0 μ mol of sodium p-hydroxybenzoate, not less than 7.0 units of glucose oxidase, and not less than 0.5 units of peroxidase, and buffered to a pH of 7.0 \pm 0.1.

Suitability—When used for determining glucose in Inulin, ascertain that no significant color results by reaction with fructose, and that a suitable absorbance-versus-concentration slope is obtained with glucose.

[NOTE—A suitable grade is available, as a concentrate, from Worthington Diagnostics, Division of Millipore Corp., www.millipore.com.]

Glycerin Base TS—To 200 g of glycerin add water to bring the total weight to 235 g. Add 140 mL of 1 N sodium hydroxide and 50 mL of water.

Gold Chloride TS—Dissolve 1 g of gold chloride in 35 mL of water.

Hydrogen Peroxide TS—Use *Hydrogen Peroxide Topical Solution* (USP monograph).

Hydrogen Sulfide TS—A saturated solution of hydrogen sulfide, made by passing H_2S into cold water. Store it in small, dark amber-colored bottles, filled nearly to the top. It is unsuitable unless it possesses a strong odor of H_2S , and unless it produces at once a copious precipitate of sulfur when added to an equal volume of ferric chloride TS. Store in a cold, dark place.

Hydroxylamine Hydrochloride TS—Dissolve 3.5 g of hydroxylamine hydrochloride in 95 mL of 60% alcohol, and add 0.5 mL of bromophenol blue solution (1 in 1000 of alcohol) and 0.5 N alcoholic potassium hydroxide until a greenish tint develops in the solution. Then add 60% alcohol to make 100 mL.

8-Hydroxyquinoline TS—Dissolve 5 g of 8-hydroxyquinoline in alcohol to make 100 mL.

Indigo Carmine TS (*Sodium Indigotindisulfonate TS*)—Dissolve a quantity of sodium indigotindisulfonate, equivalent to 180 mg of $\text{C}_{16}\text{H}_8\text{N}_2\text{O}_2(\text{SO}_3\text{Na})_2$, in water to make 100 mL. Use within 60 days.

Indophenol-Acetate TS (for the assay of *Corticotropin Injection*)—To 60 mL of standard dichlorophenol-indophenol solution (see in the section *Volumetric Solutions*) add water to make 250 mL. Add to the resulting solution an equal volume of sodium acetate solution freshly prepared by dissolving 13.66 g of anhydrous sodium acetate in water to make 500 mL and adjusting with 0.5 N acetic acid to a pH of 7. Store in a refrigerator, and use within 2 weeks.

Intestinal Fluid, Simulated, TS—Dissolve 6.8 g of monobasic potassium phosphate in 250 mL of water, mix, and add 77 mL of 0.2 N sodium hydroxide and 500 mL of water. Add 10.0 g of pancreatin, mix, and adjust the resulting solution with either 0.2 N sodium hydroxide or 0.2 N hydrochloric acid to a pH of 6.8 ± 0.1 . Dilute with water to 1000 mL.

Iodine TS—Use 0.1 N Iodine (see in the section *Volumetric Solutions*).

Iodine, Diluted TS—Transfer 10.0 mL of 0.1 N iodine VS to a 100-mL volumetric flask, dilute with water to volume, and mix.

Iodine Monochloride TS—Dissolve 10 g of potassium iodide and 6.44 g of potassium iodate in 75 mL of water in a glass-stoppered container. Add 75 mL of hydrochloric acid and 5 mL of chloroform, and adjust to a faint iodine color (in the chloroform) by adding dilute potassium iodide or potassium iodate solution. If much iodine is liberated, use a stronger solution of potassium iodate than 0.01 M at first, making the final adjustment with the 0.01 M potassium iodate. Store in a dark place, and readjust to a faint iodine color as necessary.

Iodine and Potassium Iodide TS 1—Dissolve 500 mg of iodine and 1.5 g of potassium iodide in 25 mL of water.

Iodine and Potassium Iodide TS 2—Dissolve 12.7 g of iodine and 20 g of potassium iodide in water, and dilute with water to 1000.0 mL. To 10.0 mL of this solution, add 0.6 g of potassium iodide, and dilute with water to 100.0 mL. Prepare immediately before use.

Iodine and Potassium Iodide TS 3—Dissolve 0.127 g of iodine and 0.20 g of potassium iodide in water, and dilute with water to 10.0 mL.

Iodobromide TS—Dissolve 20 g of iodine monobromide in glacial acetic acid to make 1000 mL. Store in glass containers, protected from light.

Iodochloride TS—Dissolve 16.5 g of iodine monochloride in 1000 mL of glacial acetic acid.

Iodoplatinate TS—Dissolve 300 mg of platonic chloride in 97 mL of water. Immediately prior to use, add 3.5 mL of potassium iodide TS, and mix.

Iron-Phenol TS (*Iron-Kober Reagent*)—Dissolve 1.054 g of ferrous ammonium sulfate in 20 mL of water, and add 1 mL of sulfuric acid and 1 mL of 30 percent hydrogen peroxide. Mix, heat until effervescence ceases, and dilute with water to 50 mL. To 3 volumes of this solution contained in a volumetric flask add sulfuric acid, with cooling, to make 100 volumes. Purify phenol by distillation, discarding the first 10% and the last 5%, collecting the distillate, with exclusion of moisture, in a dry, tared glass-stoppered flask of about twice the volume of the phenol. Solidify the phenol in an ice bath, breaking the top crust with a glass rod to ensure complete crystallization. Weigh the flask and its contents, add to the phenol 1.13 times its weight of the iron-sulfuric acid solution prepared as directed, insert the stopper in the flask, and allow to stand, without cooling but with occasional mixing, until the phenol is liquefied. Shake the mixture vigorously until mixed, allow to stand in the dark for 16 to 24 hours, and again weigh the flask and its contents. To the mixture add 23.5% of its weight of a solution of 100 volumes of sulfuric acid in 110 volumes of water, mix, transfer to dry glass-stoppered bottles, and store in the dark, protected from atmospheric moisture. Use within 6 months. Dispense the reagent from a small-bore buret, arranged to exclude moisture, capable of delivering 1 mL in 30 seconds or less, and having no lubricant, other than reagent, on its stopcock. Wipe the buret tip with tissue before each addition.

Iron Salicylate TS—Dissolve 500 mg of ferric ammonium sulfate in 250 mL of water containing 10 mL of diluted sulfuric acid, and add water to make 500 mL. To 100 mL of the resulting solution add 50 mL of a 1.15% solution of sodium salicylate, 20 mL of diluted acetic acid, and 80 mL of a 13.6% solution of sodium acetate, then add water to make 500 mL. Store in a well-closed container. Protect from light. Use within 2 weeks.

Lanthanum Nitrate TS—Dissolve 5.0 g of lanthanum nitrate hexahydrate in 100 mL of water.

Lead Acetate TS—Dissolve 9.5 g of clear, transparent crystals of lead acetate in recently boiled water to make 100 mL. Store in well-stoppered bottles.

Lead Acetate TS, Alcoholic—Dissolve 2 g of clear, transparent crystals of lead acetate in alcohol to make 100 mL. Store in tight containers.

Lead Subacetate TS—Dissolve 40.0 g of lead acetate in 90 mL of carbon dioxide-free water. Adjust with 10 M sodium hydroxide to a pH of 7.5, centrifuge, and use the clear supernatant. It contains NLT 16.7% (w/w) and NMT 17.4% (w/w) of Pb in a form corresponding to the formula $\text{C}_8\text{H}_{14}\text{O}_{10}\text{Pb}_3$. The solution remains clear when stored in a well-closed container.

Lead Subacetate TS, Diluted—Dilute 3.25 mL of lead subacetate TS with water, recently boiled and cooled, to make 100 mL. Store in small, well-filled, tight containers.

Litmus TS—Digest 25 g of powdered litmus with three successive 100-mL portions of boiling alcohol, continuing each extraction for about 1 hour. Filter, wash with alcohol, and discard the alcohol filtrate. Macerate the residue with about 25 mL of cold water for 4 hours, filter, and discard the filtrate. Finally digest the residue with 125 mL of boiling water for 1 hour, cool, and filter.

Locke-Ringer's Solution—See *Locke-Ringer's TS*.

Locke-Ringer's TS (*Locke-Ringer's Solution*)—

Sodium Chloride	9.0 g
Potassium Chloride	0.42 g
Calcium Chloride	0.24 g
Magnesium Chloride	0.2 g
Sodium Bicarbonate	0.5 g
Dextrose	0.5 g
Water, recently distilled from a hard-glass flask, a sufficient quantity to make	1000 mL

Prepare fresh each day. The constituents (except the dextrose and the sodium bicarbonate) may be made up in stock solutions and diluted as needed.

Magnesia Mixture TS—Dissolve 5.5 g of magnesium chloride and 7 g of ammonium chloride in 65 mL of water, add 35 mL of ammonia TS, set the mixture aside for a few days in a well-stoppered bottle, and filter. If the solution is not perfectly clear, filter it before using.

Magnesium Sulfate TS—Dissolve 12 g of crystals of magnesium sulfate, selected for freedom from efflorescence, in water to make 100 mL.

Malachite Green TS—Dissolve 1 g of malachite green oxalate in 100 mL of glacial acetic acid.

Mallory's Stain—Dissolve 500 mg of water-soluble aniline blue, 2 g of orange G, and 2 g of oxalic acid in 100 mL of water.

Mayer's Reagent—See *Mercuric-Potassium Iodide TS*.

Mercuric Acetate TS—Dissolve 6.0 g of mercuric acetate in glacial acetic acid to make 100 mL. Store in tight containers, protected from direct sunlight.

Mercuric-Ammonium Thiocyanate TS—Dissolve 30 g of ammonium thiocyanate and 27 g of mercuric chloride in water to make 1000 mL.

Mercuric Bromide TS, Alcoholic—Dissolve 5 g of mercuric bromide in 100 mL of alcohol, employing gentle heat to facilitate solution. Store in glass containers, protected from light.

Mercuric Chloride TS—Dissolve 6.5 g of mercuric chloride in water to make 100 mL.

Mercuric Iodide TS (Valser's Reagent)—Slowly add potassium iodide solution (1 in 10) to red mercuric iodide until almost all of the latter is dissolved, and filter off the excess. A solution containing 10 g of potassium iodide in 100 mL dissolves approximately 14 g of HgI_2 at 20°.

Mercuric Nitrate TS—Dissolve 40 g of mercuric oxide (red or yellow) in a mixture of 32 mL of nitric acid and 15 mL of water. Store in glass containers, protected from light.

Mercuric-Potassium Iodide TS (Mayer's Reagent)—Dissolve 1.358 g of mercuric chloride in 60 mL of water. Dissolve 5 g of potassium iodide in 10 mL of water. Mix the two solutions, and dilute with water to 100 mL.

Mercuric-Potassium Iodide TS, Alkaline (Nessler's Reagent)—Dissolve 143 g of sodium hydroxide in 700 mL of water. Dissolve 50 g of red mercuric iodide and 40 g of potassium iodide in 200 mL of water. Pour the iodide solution into the hydroxide solution, and dilute with water to 1000 mL. Allow to settle, and use the clear supernatant.

Mercuric Sulfate TS (Denigès' Reagent)—Mix 5 g of yellow mercuric oxide with 40 mL of water, and while stirring slowly add 20 mL of sulfuric acid, then add another 40 mL of water, and stir until completely dissolved.

Mercurous Nitrate TS—Dissolve 15 g of mercurous nitrate in a mixture of 90 mL of water and 10 mL of diluted nitric acid. Store in dark, amber-colored bottles in which a small globule of mercury has been placed.

Metaphenylenediamine Hydrochloride TS—Dissolve 1 g of metaphenylenediamine hydrochloride in 200 mL of water. The solution must be colorless when used. If necessary, decolorize by heating with activated charcoal.

Metaphosphoric-Acetic Acids TS—Dissolve 15 g of metaphosphoric acid in 40 mL of glacial acetic acid and sufficient water to make 500 mL. Store in a cold place, and use within 2 days.

Methoxyphenylacetic TS—Dissolve 2.7 g of methoxyphenylacetic acid in 6 mL of *Tetramethylammonium Hydroxide TS*, and add 20 mL of dehydrated alcohol. Store in a polyethylene container.

Methyl Orange TS—Dissolve 100 mg of methyl orange in 100 mL of water, and filter if necessary.

Methyl Purple TS—Use *Methyl Red-Methylene Blue TS*.

Methyl Red TS—Dissolve 100 mg of methyl red in 100 mL of alcohol, and filter if necessary.

Methyl Red TS 2—To 1.86 mL of 0.1 M sodium hydroxide and 50 mL of alcohol, add 50 mg of methyl red, and dilute with water to 100 mL.

Methyl Red TS, Methanolic—Dissolve 1 g of methyl red in 100 mL of methanol, and filter, if necessary. Store protected from light, and use within 21 days.

Methyl Red-Methylene Blue TS—Add 10 mL of methyl red TS to 10 mL of methylene blue TS, and mix.

Methyl Violet TS—Use *Crystal Violet TS*.

Methyl Yellow TS—Prepare a solution containing 0.10 mg per mL in alcohol.

Methyl Yellow-Methylene Blue TS—Dissolve 1 g of methyl yellow and 100 mg of methylene blue in 125 mL of methanol.

3-Methyl-2-benzothiazolinone Hydrazone Hydrochloride TS—Dissolve 0.1 g of 3-methyl-2-benzothiazolinone hydrazone hydrochloride monohydrate in 10 mL of water, dilute the resulting solution with methanol to 100 mL, and mix.

Methylene Blue TS—Dissolve 125 mg of methylene blue in 100 mL of alcohol, and dilute with alcohol to 250 mL.

Methylthionine Perchlorate TS—To 500 mL of potassium perchlorate solution (1 in 1000) add dropwise, with constant shaking, methylene blue solution (1 in 100) until a slight, permanent turbidity results. Allow the precipitate to settle, decant the supernatant through paper, and use only the clear solution.

Millon's Reagent—To 2 mL of mercury in a conical flask add 20 mL of nitric acid. Shake the flask under a hood to break up the mercury into small globules. After about 10 minutes, add 35 mL of water, and, if a precipitate or crystals appear, add sufficient dilute nitric acid (1 in 5, prepared from nitric acid from which the oxides have been removed by blowing air through it until it is colorless) to dissolve the separated solid. Add sodium hydroxide solution (1 in 10) dropwise, with thorough mixing, until the curdy precipitate that forms after the addition of each drop no longer redissolves but is dispersed to form a suspension. Add 5 mL more of the dilute nitric acid, and mix. Prepare this solution fresh.

Molybdo-phosphotungstate TS (Folin-Denis Reagent)—To about 350 mL of water contained in a round-bottom flask add 50 g of sodium tungstate, 12 g of phosphomolybdic acid, and 25 mL of phosphoric acid. Boil the mixture under a reflux condenser for 2 hours, then cool, dilute with water to 500 mL, and mix. Store in tight containers, protected from light, and in a cold place.

1-Naphthol Reagent—Dissolve 1 g of 1-naphthol in 25 mL of methanol. Prepare this solution fresh.

1-Naphthol TS—Use *1-Naphthol Reagent*.

2-Naphthol TS (Betanaphthol TS)—Dissolve 1 g of 2-naphthol in 100 mL of sodium hydroxide solution (1 in 100).

p-Naphtholbenzein TS—Dissolve 250 mg of p-naphtholbenzein in 100 mL of glacial acetic acid.

N-(1-Naphthyl)ethylenediamine Dihydrochloride TS—Dissolve 100 mg of N-(1-naphthyl)ethylenediamine dihydrochloride in 100 mL of a mixture of 7 parts of acetone and 3 parts of water.

Nessler's Reagent—See *Mercuric-Potassium Iodide TS, Alkaline*.

Neutral Red TS—Dissolve 100 mg of neutral red in 100 mL of 50% alcohol.

Nickel Standard Solution TS—Dissolve 4.78 g of nickel (II) sulfate heptahydrate in water, and dilute with water to 1000 mL. Immediately prior to use, dilute 10.0 mL of the solution so obtained with water to 1000 mL. Suitable nickel standard solutions are also available commercially.

Ninhydrin TS—Use *Triketohydrindene Hydrate TS*.

p-Nitroaniline TS—To 350 mg of p-nitroaniline add 1.5 mL of hydrochloric acid, and mix. Dilute with water to 50 mL, mix, and allow to settle. Place 5 mL of the clear supernatant in a 100-mL volumetric flask, and immerse it in an ice bath. While it is in the ice bath, add 1 mL of hydrochloric acid, then add, in small portions, 2 mL of sodium

nitrite solution (1 in 100), dilute with water to volume, and mix.

Nitrophenanthroline TS—Dissolve 150 mg of 5-nitro-1,10-phenanthroline in 15 mL of freshly prepared ferrous sulfate solution (1 in 140).

Oracet Blue B TS—A 1 in 200 solution of oracet blue B in glacial acetic acid.

Orthophenanthroline TS—Dissolve 150 mg of orthophenanthroline in 10 mL of a solution of ferrous sulfate, prepared by dissolving 700 mg of clear crystals of ferrous sulfate in 100 mL of water. The ferrous sulfate solution must be prepared immediately before dissolving the orthophenanthroline. Store in well-closed containers.

Oxalic Acid TS—Dissolve 6.3 g of oxalic acid in water to make 100 mL.

Palladium Chloride TS, Buffered—Weigh 500 mg of palladium chloride into a 250-mL beaker, add 5 mL of concentrated hydrochloric acid, and warm the mixture on a steam bath. Add 200 mL of hot water in small increments with continued heating until solution is complete. Transfer the solution to a 250-mL volumetric flask, and dilute with water to volume. Transfer 50 mL to a 100-mL volumetric flask. Add 10 mL of 1 M sodium acetate and 9.6 mL of 1 N hydrochloric acid. Dilute with water to volume.

Perchloric Acid TS—Dilute 8.5 mL of perchloric acid with water to 100 mL.

Phenol TS—Dissolve 1.2 g of phenol in alcohol to make 10 mL. Prepare weekly.

Phenol Red TS (*Phenolsulfonphthalein TS*)—Dissolve 100 mg of phenolsulfonphthalein in 100 mL of alcohol, and filter if necessary.

pH 4.7 Phenol Red TS—Dissolve 33 mg of phenolsulfonphthalein in 1.5 mL of 2 N sodium hydroxide solution, dilute with water to 100 mL, and mix (*Solution A*). Dissolve 25 mg of ammonium sulfate in 235 mL of water, add 105 mL of 2 N sodium hydroxide solution and 135 mL of 2 N acetic acid, and mix (*Solution B*). Add 25 mL of *Solution A* to *Solution B*, and mix. If necessary, adjust the pH of this solution to 4.7.

Phenoldisulfonic Acid TS—Dissolve 2.5 g of phenol in 15 mL of sulfuric acid in a flask of suitable capacity. Add 7.5 mL of fuming sulfuric acid, stir well, and heat at 100° for 2 hours. Transfer the product, while still fluid, to a glass-stoppered bottle, and, when desired for use, warm in a water bath until liquefied.

Phenolphthalein TS—Dissolve 1 g of phenolphthalein in 100 mL of alcohol.

Phenylhydrazine Acetate TS—Dissolve 10 mL of phenylhydrazine and 5 mL of glacial acetic acid in water to make 100 mL.

Phenylhydrazine-Sulfuric Acid TS—Dissolve 65 mg of phenylhydrazine hydrochloride in 100 mL of a cooled mixture of equal volumes of sulfuric acid and water.

Phloroglucinol TS—Dissolve 500 mg of phloroglucinol in 25 mL of alcohol. Store in tight containers, protected from light.

Phosphatic Enzyme TS—Dissolve 5 g of phosphatic enzyme in water to make 50 mL. Prepare this solution fresh.

Phosphomolybdic Acid TS—Dissolve 20 g of phosphomolybdic acid in alcohol to make 100 mL. Filter the solution, and use only the clear filtrate.

Phosphotungstic Acid TS—Dissolve 1 g of phosphotungstic acid in water to make 100 mL.

Picrate TS, Alkaline—Mix 20 mL of trinitrophenol solution (1 in 100) with 10 mL of sodium hydroxide solution (1 in 20), dilute with water to 100 mL, and mix. Use within 2 days.

Picric Acid TS—See *Trinitrophenol TS*.

Platinic Chloride TS—Dissolve 2.6 g of platinic chloride in water to make 20 mL.

Platinum-Cobalt TS—Dissolve 1.246 g of potassium chloroplatinate (K_2PtCl_6) and 1.000 g of cobalt chloride ($CoCl_2 \cdot 6H_2O$) in water, add 100 mL of hydrochloric acid, and dilute with water to 1 L.

Potassium Acetate TS—Dissolve 10 g of potassium acetate in water to make 100 mL.

Potassium-Bismuth Iodide TS—Dissolve 12.5 g of tartaric acid in 25 mL of water, then dissolve 1.06 g of bismuth subnitrate in this mixture (*Solution A*). Dissolve 20 g of potassium iodide in 25 mL of water (*Solution B*). Dissolve 100 g of tartaric acid in 450 mL of water (*Solution C*). Add *Solutions A* and *B* to *Solution C*, and mix.

Potassium Carbonate TS—Dissolve 7 g of anhydrous potassium carbonate in water to make 100 mL.

Potassium Chromate TS—Dissolve 10 g of potassium chromate in water to make 100 mL.

Potassium Dichromate TS—Dissolve 7.5 g of potassium dichromate in water to make 100 mL.

Potassium Ferricyanide TS—Dissolve 1 g of potassium ferricyanide in 10 mL of water. Prepare this solution fresh.

Potassium Ferrocyanide TS—Dissolve 1 g of potassium ferrocyanide in 10 mL of water. Prepare this solution fresh.

Potassium Hydroxide TS—Dissolve 6.5 g of potassium hydroxide in water to make 100 mL.

Potassium Hydroxide TS, Alcoholic—Use 0.5 N Potassium Hydroxide, Alcoholic (see in the section *Volumetric Solutions*).

Potassium Hydroxide TS 2, Alcoholic—Dissolve 130 g of potassium hydroxide, with cooling, in 200 mL of water. Add alcohol to 1000 mL. Store in a well-stoppered dark glass bottle.

Potassium Iodide TS—Dissolve 16.5 g of potassium iodide in water to make 100 mL. Store in light-resistant containers.

Potassium Iodide and Starch TS—Dissolve 0.75 g of potassium iodide in 100 mL of water. Heat to boiling, and add, with stirring, a solution of 0.5 g of soluble starch in 35 mL of water. Boil for 2 minutes, and allow to cool.

Sensitivity—Mix 15 mL in 0.05 mL of glacial acetic acid and 0.3 mL of diluted iodine TS: a blue color is produced.

Potassium Iodoplatinate TS—Dissolve 200 mg of platinic chloride in 2 mL of water, mix with 25 mL of potassium iodide solution (1 in 25), and add water to make 50 mL.

Potassium Permanganate TS—Use 0.1 N Potassium Permanganate (see in the section *Volumetric Solutions*).

Potassium Pyroantimonate TS—Dissolve 2 g of potassium pyroantimonate in 85 mL of hot water. Cool quickly, and add 50 mL of a solution containing 50 mg/mL of potassium hydroxide in water and 1 mL of sodium hydroxide solution (8.5 in 100). Allow to stand for 24 h, filter, and dilute with water to 150 mL.

Potassium Sulfate TS—Dissolve 1 g of potassium sulfate in water to make 100 mL.

Potassium Thiocyanate TS—Dissolve 9.7 g of potassium thiocyanate in water to make 100 mL.

Pyridine-Pyrazolone TS—To 100 mL of a saturated solution of 1-phenyl-3-methyl-2-pyrazolone-5-one add 20 mL of a 1 in 1000 solution of 3,3'-dimethyl-1,1'-diphenyl-[4,4'-bi-2-pyrazoline]-5,5'-dione in pyridine. Store in a dark bottle, and use within 3 days.

Pyrogallol TS, Alkaline—Dissolve 500 mg of pyrogallol in 2 mL of water. Dissolve 12 g of potassium hydroxide in 8 mL of water. The solutions should be freshly prepared and mixed immediately before use.

Quinaldine Red TS—Dissolve 100 mg of quinaldine red in 100 mL of alcohol.

Quinone TS—Dissolve 500 mg of *p*-benzoquinone in 2.5 mL of glacial acetic acid, and dilute with alcohol to 50 mL. Prepare this solution fresh daily.

Resorcinol TS—Dissolve 1 g of resorcinol in hydrochloric acid to make 100 mL.

Ruthenium Red TS—Dissolve 10 g of lead acetate in water, dilute with water to 100 mL, and add 80 mg of ruthenium red. The solution is wine-red in color. [NOTE—If necessary, add additional ruthenium red to obtain a wine-red color.]

Saline TS—Dissolve 9.0 g of sodium chloride in water to make 1000 mL.

[NOTE—Where pyrogen-free saline TS is specified in this Pharmacopeia, saline TS that has met the requirements of the *Pyrogen Test* (151) is to be used.]

Saline TS, Pyrogen-Free—See *Saline TS*.

Schweitzer's Reagent—See *Cupric Oxide, Ammoniated, TS*.

Silver–Ammonia–Nitrate TS—Dissolve 1 g of silver nitrate in 20 mL of water. Add ammonia TS, dropwise, with constant stirring, until the precipitate is almost but not entirely dissolved. Filter, and store in tight, light-resistant containers.

Silver–Ammonium Nitrate TS—See *Silver–Ammonia–Nitrate TS*.

Silver Diethyldithiocarbamate TS—Dissolve 1 g of silver diethyldithiocarbamate in 200 mL of pyridine from a freshly opened bottle or that which has been recently distilled. Store in light-resistant containers, and use within 30 days.

Silver Nitrate TS—Use 0.1 N *Silver Nitrate* (see in the section *Volumetric Solutions*).

Simulated Gastric Fluid TS—See *Gastric Fluid, Simulated, TS*.

Simulated Intestinal Fluid TS—See *Intestinal Fluid, Simulated, TS*.

Sodium Acetate TS—Dissolve 13.6 g of sodium acetate in water to make 100 mL.

Sodium Alizarinsulfonate TS—Dissolve 100 mg of sodium alizarinsulfonate in 100 mL of water, and filter.

Sodium Aminoacetate TS (*Sodium Glycinate TS*)—Dissolve 3.75 g of aminoacetic acid in about 500 mL of water, add 2.1 g of sodium hydroxide, and dilute with water to 1000 mL. Mix 9 mL of the resulting solution with 1 mL of dilute glacial acetic acid (1 in 300). This test solution has a pH between 10.4 and 10.5.

Sodium Bisulfite TS—Dissolve 10 g of sodium bisulfite in water to make 30 mL. Prepare this solution fresh.

Sodium Bitartrate TS—Dissolve 1 g of sodium bitartrate in water to make 10 mL. Prepare this solution fresh.

Sodium Carbonate TS—Dissolve 10.6 g of anhydrous sodium carbonate in water to make 100 mL.

Sodium Chloride TS, Alkaline—Dissolve 2 g of sodium hydroxide in 100 mL of water, saturate the solution with sodium chloride, and filter.

Sodium Citrate TS—Dissolve 73.5 g of sodium citrate dihydrate in water to make 250 mL.

Sodium Citrate TS, Alkaline—Dissolve 50 g of sodium citrate dihydrate and 2.5 g of sodium hydroxide in water to make 250 mL.

Sodium Cobaltinitrite TS—Dissolve 10 g of sodium cobaltinitrite in water to make 50 mL, and filter if necessary.

Sodium Fluoride TS—Dry about 500 mg of sodium fluoride at 200° for 4 hours. Accurately weigh 222 mg of the dried material, and dissolve in water to make 100.0 mL. Pipet 10 mL of this solution into a 1-L volumetric flask, and dilute with water to volume. Each mL of this solution corresponds to 0.01 mg of fluorine (F).

Sodium Hydrosulfite TS, Alkaline—Dissolve 25 g of potassium hydroxide in 35 mL of water, and 50 g of sodium hydrosulfite in 250 mL of water. When the test solution is required, mix 40 mL of the hydroxide solution with the 250 mL of the hydrosulfite solution. Prepare this solution fresh.

Sodium Hydroxide TS—Dissolve 4.0 g of sodium hydroxide in water to make 100 mL.

Sodium Hydroxide TS 2—Transfer 8.5 g of sodium hydroxide to a 100-mL volumetric flask, and dissolve in and dilute with water to volume.

Sodium Hydroxide TS 3—Prepare a 420-mg/mL solution of sodium hydroxide in water.

Sodium Hypobromite TS—To a solution of 20 g of sodium hydroxide in 75 mL of water add 5 mL of bromine. After solution has taken place, dilute with water to 100 mL. Prepare this solution fresh.

Sodium Hypochlorite TS—Use *Sodium Hypochlorite Solution* (see in the section *Reagent Specifications*).

Sodium Iodoxyhydroxyquinolinesulfonate TS—Dissolve 8.8 g of iodoxyhydroxyquinoline sulfonic acid in 200 mL of water, and add 6.5 mL of 4 N sodium hydroxide. Dilute with water to 250 mL, mix, and filter.

Sodium Nitroferricyanide TS—Dissolve 1 g of sodium nitroferricyanide in water to make 20 mL. Prepare this solution fresh.

Dibasic Sodium Phosphate TS—Dissolve 12 g of dibasic sodium phosphate in water to make 100 mL.

Sodium Phosphotungstate TS—To a solution of 20 g of sodium tungstate in 100 mL of water add sufficient phosphoric acid to impart a strongly acid reaction to litmus, and filter. When required for use, decant the clear solution from any sediment that may be present. Store in tight, light-resistant containers.

Sodium Sulfide TS—Dissolve 1 g of sodium sulfide in water to make 10 mL. Prepare this solution fresh.

Sodium Tartrate TS—Dissolve 11.5 g of sodium tartrate in water to make 100 mL.

Sodium Tetraphenylboron TS—Dissolve 1.2 g of sodium tetraphenylboron in water to make 200 mL. If necessary, stir for 5 minutes with 1 g of aluminum oxide, and filter to clarify.

Sodium Thioglycolate TS—Dissolve 1.5 g of sodium thioglycolate in 450 mL of water, and add 50 mL of alcohol. Use within 3 days.

Sodium Thiosulfate TS—Use 0.1 N *Sodium Thiosulfate* (see in the section *Volumetric Solutions*).

Standard Lead Solution—See under *Heavy Metals* (231).

Stannous Chloride, Acid, TS—Dissolve 8 g of stannous chloride in 500 mL of hydrochloric acid. Store in glass containers, and use within 3 months.

Stannous Chloride, Acid, Stronger, TS—Dissolve 40 g of stannous chloride in 100 mL of hydrochloric acid. Store in glass containers, and use within 3 months.

Starch TS—Mix 1 g of soluble starch with 10 mg of red mercuric iodide and sufficient cold water to make a thin paste. Add 200 mL of boiling water, and boil for 1 minute with continuous stirring. Cool, and use only the clear solution. [NOTE—Commercially available, stabilized starch indicator solutions may be used, including mercury-free solutions preserved with other compounds such as salicylic acid.]

Starch, Iodide-Free, TS—Mix 1 g of soluble starch with sufficient cold water to make a thin paste. While stirring, add 100 mL of boiling water, and allow to cool. Prepare this solution immediately before use. Iodide-free starch TS shows a blue color when 20 mL of potassium iodide solution (1 in 400) and 0.05 mL of an iodine–potassium iodide solution (prepared by dissolving 127 mg of iodine and 800 mg of potassium iodide in water and diluting with water to 100 mL) are added to 1 mL of the iodide-free starch TS.

Starch Iodide Paste TS—Heat 100 mL of water in a 250-mL beaker to boiling, add a solution of 0.75 g of potassium iodide in 5 mL of water, then add 2 g of zinc chloride dissolved in 10 mL of water, and, while the solution is boiling, add, with stirring, a smooth suspension of 5 g of soluble starch in 30 mL of cold water. Continue to boil for 2 minutes, then cool. Store in well-closed containers in a cold place.

Starch iodide paste TS must show a definite blue streak when a glass rod, dipped in a mixture of 1 mL of 0.1 M sodium nitrite, 500 mL of water, and 10 mL of hydrochloric acid, is streaked on a smear of the paste.

Starch–Potassium Iodide TS—Dissolve 500 mg of potassium iodide in 100 mL of freshly prepared starch TS. Prepare this solution fresh.

Stronger Cupric Acetate TS—See *Cupric Acetate TS, Stronger*.

Sudan III TS—Dissolve 0.05 g of Sudan III in 25 mL of alcohol, with warming if necessary. Cool, add 25 mL of glycerin, and mix. Filter if undissolved material persists.

Sudan IV TS—Dissolve 0.5 g of Sudan IV in chloroform to make 100 mL.

Sulfanilic Acid TS—Dissolve 800 mg of sulfanilic acid in 100 mL of acetic acid. Store in tight containers.

Diazotized Sulfanilic Acid TS—Dissolve 0.9 g of sulfanilic acid in 9 mL of hydrochloric acid with warming, and dilute with water to 100 mL. Cool 10 mL of this solution in iced water, and add 10 mL of a sodium nitrite solution (4.5 in 100) previously cooled in iced water. Allow to stand at 0° for at least 15 minutes (the solution may be kept for 3 days at this temperature). Immediately before use, add 20 mL of sodium carbonate solution (1 in 10).

Sulfanilic-1-Naphthylamine TS—Dissolve 500 mg of sulfanilic acid in 150 mL of acetic acid. Dissolve 100 mg of 1-naphthylamine hydrochloride in 150 mL of acetic acid, and mix the two solutions. The pink color that may develop on standing can be removed by treatment with zinc.

Sulfanilic- α -Naphthylamine TS—See *Sulfanilic-1-Naphthylamine TS*.

Sulfomolybdic Acid TS—Dissolve, with the aid of heat, 2.5 g of ammonium molybdate in 20 mL of water, add 50 mL of 12 N sulfuric acid, and dilute with water to 100 mL. Store this solution in a polyethylene container.

Sulfuric Acid TS—Add a quantity of sulfuric acid of known concentration to sufficient water to adjust the final concentration to between 94.5% and 95.5% (w/w) of H₂SO₄.

[NOTE—Since the acid concentration may change upon standing or upon intermittent use, the concentration should be checked frequently and solutions assaying more than 95.5% or less than 94.5% discarded.]

Sulfuric Acid-Formaldehyde TS—Add 1 drop of formaldehyde TS to each mL of sulfuric acid, and mix. Prepare this solution fresh.

Tannic Acid TS—Dissolve 1 g of tannic acid in 1 mL of alcohol, and dilute with water to 10 mL. Prepare this solution fresh.

Tartaric Acid TS—Dissolve 3 g of tartaric acid in water to make 100 mL. Prepare this solution fresh.

Tetrabromophenolphthalein Ethyl Ester TS—Dissolve 100 mg of tetrabromophenolphthalein ethyl ester in 90 mL of glacial acetic acid, and dilute with glacial acetic acid to 100 mL. Prepare this solution fresh.

Tetramethylammonium Hydroxide TS—Use an aqueous solution containing, in each 100 mL, the equivalent of 10 g of anhydrous tetramethylammonium hydroxide.

Thioacetamide TS—Dissolve 4 g of thioacetamide in 100 mL of water.

Thioacetamide-Glycerin Base TS—Mix 0.2 mL of thioacetamide TS and 1 mL of glycerin base TS, and heat in a boiling water bath for 20 seconds. Use the mixture immediately.

Thorium Nitrate TS—Dissolve 1 g of thorium nitrate in water to make 100 mL. Filter, if necessary.

Thymol Blue TS—Dissolve 100 mg of thymol blue in 100 mL of alcohol, and filter if necessary.

Thymolphthalein TS—Dissolve 100 mg of thymolphthalein in 100 mL of alcohol, and filter if necessary.

Titanium Trichloride TS—Dissolve 15 g of titanium trichloride in 100 mL of 10% hydrochloric acid solution.

Titanium Trichloride-Sulfuric Acid TS—Mix carefully 20 mL of titanium trichloride TS in 13 mL of sulfuric acid. Add sufficient 30% hydrogen peroxide to produce a yellow color. Heat until white fumes are evolved, allow to cool, and dilute with water. Repeat the evaporation and addition of water until a colorless solution is obtained. Dilute with water to 100 mL.

p-Toluenesulfonic Acid TS—Dissolve 2 g of *p*-toluenesulfonic acid in 10 mL of a mixture of 7 parts of acetone and 3 parts of water.

Triketohydrindene Hydrate TS (Ninhydrin TS)—Dissolve 200 mg of triketohydrindene hydrate in water to make 10 mL. Prepare this solution fresh.

Trinitrophenol TS (Picric Acid TS)—Dissolve the equivalent of 1 g of anhydrous trinitrophenol in 100 mL of hot water. Cool the solution, and filter if necessary.

Triphenyltetrazolium Chloride TS—Dissolve 500 mg of triphenyltetrazolium chloride in dehydrated alcohol to make 100 mL.

Xylenol Orange TS—Dissolve 100 mg of xylenol orange in 100 mL of alcohol.

Zinc Uranyl Acetate TS—Dissolve 50 g of uranyl acetate in a mixture of 15 mL of glacial acetic acid and water to make 500 mL. Then dissolve 150 g of zinc acetate in a mixture of 15 mL of glacial acetic acid and water to make 500 mL. Mix the two solutions, allow to stand overnight, and pass through a dry filter, if necessary.

VOLUMETRIC SOLUTIONS

Normal Solutions—Normal solutions are solutions that contain 1 gram equivalent weight of the active substance in each 1000 mL of solution; that is, an amount equivalent to 1.0079 g of hydrogen or 7.9997 g of oxygen. Normal solutions and solutions bearing a specific relationship to normal solutions, and used in volumetric determinations, are designated as follows: normal, 1 N; double-normal, 2 N; half-normal, 0.5 N; tenth-normal, 0.1 N; fiftieth-normal, 0.02 N; hundredth-normal, 0.01 N; thousandth-normal, 0.001 N.

Molar Solutions—Molar solutions are solutions that contain, in 1000 mL, 1 gram-molecule of the reagent. Thus, each liter of a molar solution of sulfuric acid contains 98.07 g of H₂SO₄ and each liter of a molar solution of potassium ferricyanide contains 329.25 g of K₃Fe(CN)₆. Solutions containing, in 1000 mL, one-tenth of a gram-molecule of the reagent are designated "tenth-molar," 0.1 M; and other molarities are similarly indicated.

Empirical Solutions—It is frequently difficult to prepare standard solutions of a desired theoretical normality, and this is not essential. A solution of approximately the desired normality is prepared and standardized by titration against a primary standard solution. The normality factor so obtained is used in all calculations where such empirical solutions are employed. If desired, an empirically prepared solution may be adjusted downward to a given normality provided it is strong enough to permit dilution.

All volumetric solutions, whether made by direct solution or by dilution of a stronger solution, must be thoroughly mixed by shaking before standardization. As the strength of a standard solution may change upon standing, the factor should be redetermined frequently.

When solutions of a reagent are used in several normalities, the details of the preparation and standardization are usually given for the normality most frequently required. Stronger or weaker solutions are prepared and standardized in the same general manner as described, using proportionate amounts of the reagent. It is possible in many instances to prepare lower normalities accurately by making an exact dilution of a stronger solution. Volumetric solutions prepared by dilution should be restandardized either as directed for the stronger solution or by comparison with another volumetric solution having a known ratio to the stronger solution.

Dilute solutions that are not stable, as, for instance, potassium permanganate 0.01 N and more dilute sodium thiosulfate, are preferably prepared by exactly diluting the higher normality with thoroughly boiled and cooled water on the same day they are required for use.

Blank Determinations—Where it is directed that "any necessary correction" be made by a blank determination, the determination is to be conducted with the use of the same quantities of the same reagents treated in the same manner as the solution or mixture containing the portion of the substance under assay or test, but with the substance itself omitted. Appropriate blank corrections are to be made for all Pharmacopeial titrimetric assays (see *Titrimetry* (541)).

All Pharmacopeial assays that are volumetric in nature indicate the weight of the substance being assayed to which each mL of the primary volumetric solution is equivalent. In general, these equivalents may be derived by simple calculation.

tion from the data given under *Molecular Formulas and Weights*, in the *Reference Tables*.

Preparation and Methods of Standardization of Volumetric Solutions

The following directions give only one method for standardization, but other methods of standardization, capable of yielding at least the same degree of accuracy, may be used. The values obtained in the standardization of volumetric solutions are valid for all Pharmacopeial uses of these solutions, regardless of the instrumental or chemical indicators employed in the individual monographs. Where the apparent normality or molarity of a titrant depends upon the special conditions of its use, the individual monograph sets forth the directions for standardizing the reagent in the specified context. For those salts that usually are available as certified primary standards, or that are available as highly purified salts of primary standard quality, it is permissible to prepare solutions by accurately weighing a suitable quantity of the salt and dissolving it to produce a specific volume of solution of known concentration. Acetic, hydrochloric, and sulfuric acids may be standardized against a sodium hydroxide solution that recently has been standardized against a certified primary standard.

All volumetric solutions, if practicable, are to be prepared, standardized, and used at the standard temperature of 25°. If a titration is carried out with the volumetric solution at a markedly different temperature, standardize the volumetric solution used as the titrant at that different temperature, or make a suitable temperature correction.

Acetic Acid, Double-Normal (2 N)

$\text{C}_2\text{H}_4\text{O}_2$, **60.05**

120.10 g in 1000 mL

Add 116 mL of glacial acetic acid to sufficient water to make 1000 mL after cooling to room temperature.

Ammonium Thiocyanate, Tenth-Normal (0.1 N)

NH_4SCN , **76.12**

7.612 g in 1000 mL

Dissolve about 8 g of ammonium thiocyanate in 1000 mL of water, and standardize the solution as follows.

Accurately measure about 30 mL of 0.1 N silver nitrate VS into a glass-stoppered flask. Dilute with 50 mL of water, then add 2 mL of nitric acid and 2 mL of ferric ammonium sulfate TS, and titrate with the ammonium thiocyanate solution to the first appearance of a red-brown color.

$$N = \frac{\text{mL AgNO}_3 \times N \text{ AgNO}_3}{\text{mL NH}_4\text{SCN Solution}}$$

If desirable, 0.1 N ammonium thiocyanate may be replaced by 0.1 N potassium thiocyanate where the former is directed in various tests and assays.

Bismuth Nitrate, 0.01 M

$\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$, **485.07**

1000 mL of this solution contains 4.851 g of bismuth nitrate pentahydrate

Dissolve 4.86 g of bismuth nitrate pentahydrate in 60 mL of dilute nitric acid, add 0.01 N nitric acid to make 1000 mL, and standardize the solution as follows.

Accurately measure 25 mL of the prepared bismuth nitrate solution, add 50 mL of water and 1 drop of xylenol orange TS, and titrate the solution with 0.01 M edetate disodium VS until the red color changes to yellow. Calculate the molarity factor.

Bromine, Tenth-Normal (0.1 N)

Br, **79.90**

7.990 g in 1000 mL

Dissolve 3 g of potassium bromate and 15 g of potassium bromide in water to make 1000 mL, and standardize the solution as follows.

Accurately measure about 25 mL of the solution into a 500-mL iodine flask, and dilute with 120 mL of water. Add 5 mL of hydrochloric acid, insert the stopper in the flask, and shake it gently. Then add 5 mL of potassium iodide TS, again insert the stopper, shake the mixture, allow it to stand for 5 minutes, and titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached.

Preserve in dark amber-colored, glass-stoppered bottles.

$$N = \frac{\text{mL Na}_2\text{S}_2\text{O}_3 \times N \text{ Na}_2\text{S}_2\text{O}_3}{\text{mL Br}_2 \text{ Solution}}$$

Ceric Ammonium Nitrate, Twentieth-Normal (0.05 N)

$\text{Ce}(\text{NO}_3)_4 \cdot 2\text{NH}_4\text{NO}_3$, **548.22**

2.741 g in 100 mL

Dissolve 2.75 g of ceric ammonium nitrate in 1 N nitric acid to obtain 100 mL of solution, and filter. Standardize the solution as follows.

Accurately measure 10 mL of freshly standardized 0.1 N ferrous ammonium sulfate VS into a flask, and dilute with water to about 100 mL. Add 1 drop of nitrophenanthroline TS, and titrate with the ceric ammonium nitrate solution to a colorless endpoint.

$$N = \frac{\text{mL Fe}(\text{NH}_4)_2(\text{SO}_4)_2 \times N \text{ Fe}(\text{NH}_4)_2(\text{SO}_4)_2}{\text{mL Ce}(\text{NO}_3)_4 \cdot 2\text{NH}_4\text{NO}_3}$$

Ceric Sulfate, Tenth-Normal (0.1 N)

$\text{Ce}(\text{SO}_4)_2$, **332.24**

33.22 g in 1000 mL

Use commercially available volumetric standard solution. Standardize the solution as follows.

Accurately weigh about 0.2 g of sodium oxalate, primary standard, dried according to the instructions on its label, and dissolve in 75 mL of water. Add, with stirring, 2 mL of sulfuric acid that has previously been mixed with 5 mL of water, mix well, add 10 mL of hydrochloric acid, and heat to between 70° and 75°. Titrate with 0.1 N ceric sulfate to a permanent slight yellow color. Each 6.700 mg of sodium oxalate is equivalent to 1 mL of 0.1 N ceric sulfate.

$$N = \frac{\text{mg Na}_2\text{C}_2\text{O}_4}{67.00 \times \text{mL Ce}(\text{SO}_4)_2 \text{ solution}}$$

Cupric Nitrate, Tenth-Normal (0.1 N)

$\text{Cu}(\text{NO}_3)_2 \cdot 2.5\text{H}_2\text{O}$, **232.59**

23.26 g in 1000 mL

$\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$, **241.60**

24.16 g in 1000 mL

Dissolve 23.3 g of cupric nitrate 2.5 hydrate, or 24.2 g of the trihydrate, in water to make 1000 mL. Standardize the solution as follows.

Transfer 20.0 mL of the solution to a 250-mL beaker. Add 2 mL of 5 M sodium nitrate, 20 mL of ammonium acetate TS, and sufficient water to make 100 mL. Titrate with 0.05 M edetate disodium VS. Determine the endpoint potentiometrically using a cupric ion-double junction reference

electrode system. Perform a blank determination, and make any necessary correction.

$$N = \frac{\text{mL edetate disodium (corrected for the blank)} \times M \text{ edetate disodium}}{20.0}$$

Standard Dichlorophenol–Indophenol Solution

To 50 mg of 2,6-dichlorophenol–indophenol sodium that has been stored in a desiccator over soda lime add 50 mL of water containing 42 mg of sodium bicarbonate, shake vigorously, and when the dye is dissolved, add water to make 200 mL. Filter into an amber, glass-stoppered bottle. Use within 3 days and standardize immediately before use. Standardize the solution as follows.

Accurately weigh 50 mg of USP Ascorbic Acid RS, and transfer to a glass-stoppered, 50-mL volumetric flask with the aid of a sufficient volume of metaphosphoric–acetic acids TS to make 50 mL. Immediately transfer 2 mL of the ascorbic acid solution to a 50-mL conical flask containing 5 mL of the metaphosphoric–acetic acids TS, and titrate rapidly with the dichlorophenol–indophenol solution until a distinct rose-pink color persists for at least 5 seconds. Perform a blank titration by titrating 7 mL of the metaphosphoric–acetic acids TS plus a volume of water equal to the volume of the dichlorophenol solution used in titrating the ascorbic acid solution. Express the concentration of the standard solution in terms of its equivalent in mg of ascorbic acid.

Edetate Disodium, Twentieth-Molar (0.05 M)

$\text{C}_{10}\text{H}_{14}\text{N}_2\text{Na}_2\text{O}_8 \cdot 2\text{H}_2\text{O}$, 372.24
18.61 g in 1000 mL

Dissolve 18.6 g of edetate disodium in water to make 1000 mL, and standardize the solution as follows.

Accurately weigh about 200 mg of chelometric standard calcium carbonate, previously dried at 110° for 2 hours and cooled in a desiccator, or dried according to the label instructions, transfer to a 400-mL beaker, add 10 mL of water, and swirl to form a slurry. Cover the beaker with a watch glass, and introduce 2 mL of diluted hydrochloric acid from a pipet inserted between the lip of the beaker and the edge of the watch glass. Swirl the contents of the beaker to dissolve the calcium carbonate. Wash down the sides of the beaker, the outer surface of the pipet, and the watch glass with water, and dilute with water to about 100 mL. While stirring the solution, preferably with a magnetic stirrer, add about 30 mL of the edetate disodium solution from a 50-mL buret. Add 15 mL of sodium hydroxide TS and 300 mg of hydroxy naphthol blue, and continue the titration with the edetate disodium solution to a blue endpoint.

$$M = \frac{(\text{g CaCO}_3)(1000)}{100.09 \times \text{mL EDTA}}$$

Ferric Ammonium Sulfate, Tenth-Normal (0.1 N)

$\text{FeNH}_4(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$, 482.19
48.22 g in 1000 mL

Dissolve 50 g of ferric ammonium sulfate in a mixture of 300 mL of water and 6 mL of sulfuric acid, dilute with water to 1000 mL, and mix. Standardize the solution as follows.

Accurately measure about 40 mL of the solution into a glass-stoppered flask, add 5 mL of hydrochloric acid, mix, and add a solution of 3 g of potassium iodide in 10 mL of water. Insert the stopper, allow to stand for 10 minutes, then titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. Correct for a blank run on the same quantities of the same reagents.

Store in tight containers, protected from light.

$$N = \frac{\text{mL Na}_2\text{S}_2\text{O}_3 \times N \text{ Na}_2\text{S}_2\text{O}_3}{\text{mL FeNH}_4(\text{SO}_4)_2}$$

Ferrous Ammonium Sulfate, Tenth-Normal (0.1 N)

$\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$, 392.14
39.21 g in 1000 mL

Dissolve 40 g of ferrous ammonium sulfate in a previously cooled mixture of 40 mL of sulfuric acid and 200 mL of water, dilute with water to 1000 mL, and mix. On the day of use, standardize the solution as follows.

Accurately measure 25 to 30 mL of the solution into a flask, add 2 drops of orthophenanthroline TS, and titrate with 0.1 N ceric sulfate VS until the red color is changed to pale blue.

$$N = \frac{\text{mL Ce}^{\text{IV}} \times N \text{ Ce}^{\text{IV}}}{\text{mL Fe}^{\text{II}} \text{ Solution}}$$

Hydrochloric Acid, Alcoholic, Tenth-Molar (0.1 M)

HCl, 36.46

Dilute 9.0 mL of hydrochloric acid to 1000 mL with aldehyde-free alcohol.

Hydrochloric Acid, Half-Normal (0.5 N)

HCl, 36.46

18.23 g in 1000 mL

To a 1000-mL volumetric flask containing 40 mL of water slowly add 43 mL of hydrochloric acid. Cool, and add water to volume. Standardize the solution as follows.

Accurately weigh about 2.5 g of tromethamine, dried according to the label instructions or, if this information is not available, dried at 105° for 3 h. Dissolve in 50 mL of water, and add 2 drops of bromocresol green TS. Titrate with 0.5 N hydrochloric acid to a pale yellow endpoint. Each 60.57 mg of tromethamine is equivalent to 1 mL of 0.5 N hydrochloric acid.

$$N = \frac{\text{mg tromethamine}}{121.14 \times \text{mL HCl}}$$

Hydrochloric Acid, Half-Normal (0.5 N) in Methanol

HCl, 36.46

18.23 g in 1000 mL

To a 1000-mL volumetric flask containing 40 mL of water slowly add 43 mL of hydrochloric acid. Cool, and add methanol to volume. Standardize the solution as follows.

Accurately weigh about 2.5 g of tromethamine, dried according to the label instructions or, if this information is not available, dried at 105° for 3 h. Proceed as directed under *Hydrochloric Acid, Normal (1 N)*, beginning with "Dissolve in 50 mL of water."

$$N = \frac{\text{mg tromethamine}}{121.14 \times \text{mL HCl}}$$

Hydrochloric Acid, Normal (1 N)

HCl, 36.46

36.46 g in 1000 mL

Dilute 85 mL of hydrochloric acid with water to 1000 mL. Standardize the solution as follows.

Accurately weigh about 5.0 g of tromethamine, dried according to the label instructions or, if this information is not available, dried at 105° for 3 h. Dissolve in 50 mL of water, and add 2 drops of bromocresol green TS. Titrate with 1 N

hydrochloric acid to a pale yellow endpoint. Each 121.14 mg of tromethamine is equivalent to 1 mL of 1 N hydrochloric acid.

$$N = \frac{\text{mg tromethamine}}{121.14 \times \text{mL HCl}}$$

Iodine, Tenth-Normal (0.1 N)

I, 126.90

12.69 g in 1000 mL

Dissolve about 14 g of iodine in a solution of 36 g of potassium iodide in 100 mL of water, add 3 drops of hydrochloric acid, dilute with water to 1000 mL, and standardize the solution as follows.

Transfer 25.0 mL of the iodine solution to a 250-mL flask, dilute with water to 100 mL, add 1 mL of 1 N hydrochloric acid, swirl gently to mix, and titrate with 0.1 N sodium thiosulfate VS until the solution has a pale yellow color. Add 2 mL of starch TS and continue titrating until the solution is colorless.

Preserve in amber-colored, glass-stoppered bottles.

$$N = \frac{\text{mL Na}_2\text{S}_2\text{O}_3 \times N \text{ Na}_2\text{S}_2\text{O}_3}{25}$$

Iodine, Twentieth-Normal (0.05 N)

I, 126.90

6.33 g in 1000 mL

Dissolve about 6.5 g of iodine in a solution of 18 g of potassium iodide in 100 mL of water, add 3 drops of hydrochloric acid, dilute with water to 1000 mL, and standardize the solution as follows.

Transfer 50.0 mL of the iodine solution to a 250-mL flask, dilute with water to 100 mL, add 1 mL of 1 N hydrochloric acid, swirl gently to mix, and titrate with 0.1 N sodium thiosulfate VS until the solution has a pale yellow color. Add 2 mL of starch TS, and continue titrating until the solution is colorless.

$$N = \frac{\text{mL Na}_2\text{S}_2\text{O}_3 \times N \text{ Na}_2\text{S}_2\text{O}_3}{50}$$

Iodine, Hundredth-Normal (0.01 N)

I, 126.90

1.269 g in 1000 mL

Dissolve about 1.4 g of iodine in a solution of 3.6 g of potassium iodide in 100 mL of water, add 3 drops of hydrochloric acid, dilute with water to 1000 mL, and standardize the solution as follows.

Transfer 100.0 mL of iodine solution to a 250-mL flask, add 1 mL of 1 N hydrochloric acid, swirl gently to mix, and titrate with 0.1 N sodium thiosulfate VS until the solution has a pale yellow color. Add 2 mL of starch TS, and continue titrating until the solution is colorless.

Preserve in amber-colored, glass-stoppered bottles.

$$N = \frac{\text{mL Na}_2\text{S}_2\text{O}_3 \times N \text{ Na}_2\text{S}_2\text{O}_3}{100}$$

Lead Nitrate, Hundredth-Molar (0.01 M)

Pb(NO₃)₂, 331.21

3.312 g in 1000 mL

Xylenol Orange Triturate—Triturate 1 part of xylenol orange with 99 parts of potassium nitrate.

0.1 M Lead Nitrate—Dissolve 33 g of lead nitrate in 1000 mL of water. Standardize the solution as follows. To 20.0 mL of the lead nitrate solution add 300 mL of water. Add about 50 mg of *Xylenol Orange Triturate*, and add methenamine until the solution becomes violet-pink. Titrate with 0.1 M edetate disodium VS to the yellow endpoint. Calculate the molarity.

Dilute 50.0 mL of 0.1 M Lead Nitrate to 500.0 mL with water.

Lead Perchlorate, Tenth-Molar (0.1 M)

Pb(ClO₄)₂ · 3H₂O, 460.15

46.01 g in 1000 mL

Dissolve 46 g of lead perchlorate in water, and dilute with water to 1000.0 mL. Accurately weigh about 150 mg of sodium sulfate, previously dried at 105° for 4 hours, and dissolve in 50 mL of water. Add 50 mL of a mixture of water and formaldehyde (1:1), and stir for about 1 minute. Determine the endpoint potentiometrically using a lead ion selective electrode. Perform a blank determination, and make any necessary corrections. Each 14.204 mg of sodium sulfate is equivalent to 1 mL of 0.1 M lead perchlorate.

$$M = \frac{\text{mg sodium sulfate}}{142.04 \times \text{mL lead perchlorate}}$$

Lead Perchlorate, Hundredth-Molar (0.01 M)

Pb(ClO₄)₂, 406.10

Accurately pipet 100 mL of commercially available 0.1 M lead perchlorate solution into a 1000-mL volumetric flask, add a sufficient quantity of water to make 1000 mL, and standardize the solution as follows.

Accurately pipet 50 mL of 0.01 M lead perchlorate solution, as prepared above, into a 250-mL conical flask. Add 3 mL of aqueous hexamethylenetetramine solution (2.0 g per 100 mL) and 4 drops of 0.5% xylenol orange indicator prepared by adding 500 mg of xylenol orange to 10 mL of alcohol and diluting with water to 100 mL. (Omit the alcohol if the sodium salt of the indicator is used). Titrate with 0.05 M edetate disodium VS to a yellow endpoint.

$$M = \frac{\text{mL edetate disodium} \times M \text{ edetate disodium}}{50.0}$$

Lithium Methoxide, Fiftieth-Normal (0.02 N) in Methanol

CH₃LiO, 37.97

759.6 mg in 1000 mL

Dissolve 0.12 g of freshly cut lithium metal in 150 mL of methanol, cooling the flask during addition of the metal. When the reaction is complete, add 850 mL of methanol, and mix. Store the solution preferably in the reservoir of an automatic delivery buret suitably protected from carbon dioxide and moisture. Standardize the solution by titration against benzoic acid as described under *Sodium Methoxide, Tenth-Normal (0.1 N) (in Toluene)*, but use only 100 mg of benzoic acid. Each 2.442 mg of benzoic acid is equivalent to 1 mL of 0.02 N lithium methoxide.

[NOTE—Restandardize the solution frequently.]

$$N = \frac{\text{mg benzoic acid}}{121.1 \times \text{mL lithium methoxide (corrected for the blank)}}$$

Lithium Methoxide, Tenth-Normal (0.1 N) in Chlorobenzene

CH₃OLi, 37.97

3.798 g in 1000 mL

Dissolve 700 mg of freshly cut lithium metal in 150 mL of methanol, cooling the flask during addition of the metal. When the reaction is complete, add 850 mL of chlorobenzene. If cloudiness or precipitation occurs, add sufficient methanol to clarify the solution. Store preferably in the reservoir of an automatic delivery buret suitably protected from carbon dioxide and moisture. Standardize the solution by titration against benzoic acid as described under *Sodium Methoxide, Tenth-Normal (0.1 N) (in Toluene)*.

[NOTE—Restandardize the solution frequently.]

$$N = \frac{\text{mg benzoic acid}}{121.1 \times \text{mL lithium methoxide (corrected for the blank)}}$$

Lithium Methoxide, Tenth-Normal (0.1 N) in Methanol

CH_3OLi , 37.97

3.798 g in 1000 mL

Dissolve 700 mg of freshly cut lithium metal in 150 mL of methanol, cooling the flask during addition of the metal. When the reaction is complete, add 850 mL of methanol. If cloudiness or precipitation occurs, add sufficient methanol to clarify the solution. Store preferably in the reservoir of an automatic delivery buret suitably protected from carbon dioxide and moisture. Standardize the solution by titration against benzoic acid as described under *Sodium Methoxide, Tenth-Normal (0.1 N) (in Toluene)*.

[NOTE—Restandardize the solution frequently.]

$$N = \frac{\text{mg benzoic acid}}{121.1 \times \text{mL lithium methoxide (corrected for the blank)}}$$

Lithium Methoxide, Tenth-Normal (0.1 N) in Toluene

CH_3OLi , 37.97

3.798 g in 1000 mL

Dissolve 700 mg of freshly cut lithium metal in 150 mL of methanol, cooling the flask during addition of the metal. When reaction is complete, add 850 mL of toluene. If cloudiness or precipitation occurs, add sufficient methanol to clarify the solution. Store preferably in the reservoir of an automatic delivery buret suitably protected from carbon dioxide and moisture. Standardize the solution by titration against benzoic acid as described under *Sodium Methoxide, Tenth-Normal (0.1 N) (in Toluene)*.

[NOTE—Restandardize the solution frequently.]

$$N = \frac{\text{mg benzoic acid}}{121.1 \times \text{mL lithium methoxide (corrected for the blank)}}$$

Magnesium Chloride, 0.01 M

$\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$, 203.30

2.0330 g in 1000 mL

Dissolve about 2.04 g of magnesium chloride in 1000 mL of freshly boiled and cooled water, and standardize the solution as follows.

Accurately measure 25 mL of the prepared magnesium chloride solution. Add 50 mL of water, 3 mL of ammonia-ammonium chloride buffer TS and 0.04 g of eriochrome black T-sodium chloride reagent. Titrate with 0.05 M edetate disodium VS until the red-purple color of the solution changes to blue-purple.

$$M = \frac{(\text{mL edetate disodium VS}) \times (M \text{ edetate disodium})}{\text{mL magnesium chloride}}$$

Mercuric Nitrate, Tenth-Molar (0.1 M)

$\text{Hg}(\text{NO}_3)_2$, 324.60

32.46 g in 1000 mL

Dissolve about 35 g of mercuric nitrate in a mixture of 5 mL of nitric acid and 500 mL of water, and dilute with water to 1000 mL. Standardize the solution as follows.

Transfer an accurately measured volume of about 20 mL of the solution to a conical flask, and add 2 mL of nitric acid and 2 mL of ferric ammonium sulfate TS. Cool to below 20°, and titrate with 0.1 N ammonium thiocyanate VS to the first appearance of a permanent brownish color.

$$M = \frac{\text{mL NH}_4\text{SCN} \times N \text{ NH}_4\text{SCN}}{\text{mL Hg}(\text{NO}_3)_2 \times 2}$$

Oxalic Acid, Tenth-Normal (0.1 N)

$\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$, 126.07

6.303 g in 1000 mL

Dissolve 6.45 g of oxalic acid in water to make 1000 mL. Standardize by titration against freshly standardized 0.1 N potassium permanganate VS as directed under *Potassium Permanganate, Tenth-Normal (0.1 N)*.

Preserve in glass-stoppered bottles, protected from light.

$$N = \frac{\text{mL KMnO}_4 \times N \text{ KMnO}_4}{\text{mL H}_2\text{C}_2\text{O}_4}$$

Perchloric Acid, Tenth-Normal (0.1 N) in Dioxane

Mix 8.5 mL of perchloric acid with sufficient dioxane to make 1000 mL. Standardize the solution as follows.

Accurately weigh about 700 mg of potassium biphthalate, previously crushed lightly and dried at 120° for 2 hours, and dissolve in 50 mL of glacial acetic acid in a 250-mL flask. Add 2 drops of crystal violet TS, and titrate with the perchloric acid solution until the violet color changes to bluish green. Carry out a blank determination. Each 20.423 mg of potassium biphthalate is equivalent to 1 mL of 0.1 N perchloric acid.

$$N = \frac{\text{g KHC}_8\text{H}_4\text{O}_4}{0.20423 \times \text{mL HClO}_4 \text{ solution (corrected for the blank)}}$$

Perchloric Acid, Tenth-Normal (0.1 N) in Glacial Acetic Acid

HClO_4 , 100.46

10.05 g in 1000 mL

[NOTE—Where called for in the tests and assays, this volumetric solution is specified as "0.1 N perchloric acid." Thus, where 0.1 N or other strength of this volumetric solution is specified, the solution in glacial acetic acid is to be used, unless the words "in dioxane" are stated. [See also *Perchloric Acid, Tenth-Normal (0.1 N) in Dioxane*.]]

Mix 8.5 mL of perchloric acid with 500 mL of glacial acetic acid and 21 mL of acetic anhydride, cool, and add glacial acetic acid to make 1000 mL. Alternatively, the solution may be prepared as follows. Mix 11 mL of 60 percent perchloric acid with 500 mL of glacial acetic acid and 30 mL of acetic anhydride, cool, and add glacial acetic acid to make 1000 mL.

Allow the prepared solution to stand for 1 day for the excess acetic anhydride to be combined, and determine the water content by *Method I* (see *Water Determination* (921)), except to use a test specimen of about 5 g of the 0.1 N perchloric acid that is expected to contain approximately 1 mg of water and the *Reagent* (see *Reagent* under *Method Ia* in *Water Determination* (921)) diluted such that 1 mL is equivalent to about 1 to 2 mg of water. If the water content exceeds 0.5%, add more acetic anhydride. If the solution contains no titratable water, add sufficient water to obtain a content of between 0.02% and 0.5% of water. Allow the solution to stand for 1 day, and again titrate the water con-

tent. The solution so obtained contains between 0.02% and 0.5% of water, indicating freedom from acetic anhydride.

Standardize the solution as follows.

Accurately weigh about 700 mg of potassium biphthalate, previously crushed lightly and dried at 120° for 2 hours, and dissolve it in 50 mL of glacial acetic acid in a 250-mL flask. Add 2 drops of crystal violet TS, and titrate with the perchloric acid solution until the violet color changes to blue-green. Deduct the volume of the perchloric acid consumed by 50 mL of the glacial acetic acid. Each 20.423 mg of potassium biphthalate is equivalent to 1 mL of 0.1 N perchloric acid.

$$N = \frac{\text{g KHC}_8\text{H}_4\text{O}_4}{0.20423 \times \text{mL HClO}_4 \text{ solution (corrected for the blank)}}$$

Potassium Arsenite, Tenth-Normal (0.1 N)

KAsO₂, 146.02

7.301 g in 1000 mL

Dissolve 4.9455 g of arsenic trioxide primary standard, previously dried at 105° for 1 hour, in 75 mL of 1 N potassium hydroxide. Add 40 g of potassium bicarbonate, dissolved in about 200 mL of water, and dilute with water to 1000.0 mL.

Potassium Bromate, Tenth-Normal (0.1 N)

KBrO₃, 167.00

2.784 g in 1000 mL

Dissolve 2.784 g of potassium bromate in water to make 1000 mL, and standardize the solution as follows.

Transfer an accurately measured volume of about 40 mL of the solution to a glass-stoppered flask, add 3 g of potassium iodide, and follow with 3 mL of hydrochloric acid. Allow to stand for 5 minutes, then titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. Correct for a blank run on the same quantities of the same reagents, and calculate the normality.

$$N = \frac{\text{mL Na}_2\text{S}_2\text{O}_3 \times N \text{ Na}_2\text{S}_2\text{O}_3}{\text{mL KBrO}_3 \text{ Solution}}$$

Potassium Bromide-Bromate, Tenth-Normal (0.1 N)

Dissolve 2.78 g of potassium bromate (KBrO₃) and 12.0 g of potassium bromide (KBr) in water, and dilute with water to 1000 mL. Standardize by the procedure set forth for *Potassium Bromate, Tenth-Normal (0.1 N)*.

$$N = \frac{\text{mL Na}_2\text{S}_2\text{O}_3 \times N \text{ Na}_2\text{S}_2\text{O}_3}{\text{mL KBrO}_3/\text{KBr}}$$

Potassium Dichromate, Tenth-Normal (0.1 N)

K₂Cr₂O₇, 294.18

4.903 g in 1000 mL

Dissolve about 5 g of potassium dichromate in 1000 mL of water. Standardize the solution as follows.

Transfer 25.0 mL of this solution to a glass-stoppered, 500-mL flask, add 2 g of potassium iodide (free from iodate), dilute with 200 mL of water, add 5 mL of hydrochloric acid, allow to stand for 10 minutes in a dark place, and titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached. Carry out a blank determination.

$$N = \frac{\text{mL Na}_2\text{S}_2\text{O}_3 \times N \text{ Na}_2\text{S}_2\text{O}_3}{25.0}$$

Potassium Ferricyanide, Twentieth-Molar (0.05 M)

K₃Fe(CN)₆, 329.24

16.46 g in 1000 mL

Dissolve about 17 g of potassium ferricyanide in water to make 1000 mL. Standardize the solution as follows.

Transfer 50.0 mL of this solution to a glass-stoppered, 500-mL flask, dilute with 50 mL of water, add 10 mL of potassium iodide TS and 10 mL of dilute hydrochloric acid, and allow to stand for 1 minute. Then add 15 mL of zinc sulfate solution (1 in 10), and titrate the liberated iodine with 0.1 N sodium thiosulfate VS, adding 3 mL of starch TS as the endpoint is approached.

Protect from light, and restandardize before use.

$$M = \frac{\text{mL Na}_2\text{S}_2\text{O}_3 \times N \text{ Na}_2\text{S}_2\text{O}_3}{50.0}$$

Potassium Hydroxide, Alcoholic, Half-Normal (0.5 N)

28.06 g in 1000 mL

Dissolve about 34 g of potassium hydroxide in 20 mL of water, and add aldehyde-free alcohol to make 1000 mL. Allow the solution to stand in a tightly stoppered bottle for 24 hours. Then quickly decant the clear supernatant into a suitable, tight container, and standardize the solution as follows.

Accurately measure about 25 mL of 0.5 N hydrochloric acid VS. Dilute with 50 mL of water, add 2 drops of phenolphthalein TS, and titrate with the alcoholic potassium hydroxide solution until a permanent, pale pink color is produced.

[NOTE—Store in tightly stoppered bottles, protected from light.]

$$N = \frac{\text{mL HCl} \times N \text{ HCl}}{\text{mL KOH}}$$

Potassium Hydroxide, Alcoholic, Tenth-Molar (0.1 M)

KOH, 56.11

Dilute 20 mL of 0.5 M alcoholic potassium hydroxide to 100.0 mL with aldehyde-free alcohol.

Potassium Hydroxide, Methanolic, Tenth-Normal

(0.1 N)

5.612 g in 1000 mL

Dissolve about 6.8 g of potassium hydroxide in 4 mL of water, and add methanol to make 1000 mL. Allow the solution to stand in a tightly stoppered bottle for 24 hours. Then quickly decant the clear supernatant into a suitable, tight container, and standardize the solution as follows.

Accurately measure about 25 mL of 0.1 N hydrochloric acid VS. Dilute with 50 mL of water, add 2 drops of phenolphthalein TS, and titrate with the methanolic potassium hydroxide solution until a permanent, pale pink color is produced.

[NOTE—Store in tightly stoppered bottles, protected from light.]

$$N = \frac{\text{mL HCl} \times N \text{ HCl}}{\text{mL KOH}}$$

Potassium Hydroxide, Normal (1 N)

KOH, 56.11

56.11 g in 1000 mL

Dissolve 68 g of potassium hydroxide in about 950 mL of water. Add a freshly prepared saturated solution of barium hydroxide until no more precipitate forms. Shake the mixture thoroughly, and allow it to stand overnight in a stoppered bottle. Decant the clear liquid, or filter the solution in

a tight, polyolefin bottle, and standardize by the procedure set forth for *Sodium Hydroxide, Normal (1 N)*.

$$N = \frac{g \text{ KHC}_8\text{H}_4\text{O}_4}{0.20423 \times \text{mL KOH}}$$

Potassium Iodate, Twentieth-Molar (0.05 M)

KIO₃, 214.00

10.70 g in 1000 mL

Dissolve 10.700 g of potassium iodate, previously dried at 110° to constant weight, in water to make 1000.0 mL. Standardize the solution as follows: to 15.0 mL of solution in a 250-mL iodine flask, add 3 g of potassium iodide and 3 mL of hydrochloric acid previously diluted with 10 mL of water. Stopper immediately, and allow to stand in the dark for 5 minutes. Then add 50 mL of cold water, and titrate the liberated iodine with freshly standardized 0.1 N sodium thiosulfate. Add 3 mL of starch indicator solution near the end of the titration, and continue to the absence of the blue-starch-iodine complex.

$$M = \frac{\text{mL} \times N \text{ Na}_2\text{S}_2\text{O}_3}{\text{mL KIO}_3 \times 6}$$

Potassium Permanganate, Tenth-Normal (0.1 N)

KMnO₄, 158.03

3.161 g in 1000 mL

Dissolve about 3.3 g of potassium permanganate in 1000 mL of water in a flask, and boil the solution for about 15 minutes. Insert the stopper in the flask, allow it to stand for at least 2 days, and filter through a fine-porosity, sintered-glass crucible. If necessary, the bottom of the sintered-glass crucible may be lined with a pledget of glass wool. Standardize the solution as follows.

Accurately weigh about 200 mg of sodium oxalate, dried according to the instructions on its label, and dissolve it in 250 mL of water. Add 7 mL of sulfuric acid, heat to about 70°, and then slowly add the permanganate solution from a buret, with constant stirring, until a pale pink color, which persists for 15 seconds, is produced. The temperature at the conclusion of the titration should be not less than 60°. Calculate the normality. Each 6.700 mg of sodium oxalate is equivalent to 1 mL of 0.1 N potassium permanganate.

Since potassium permanganate is reduced on contact with organic substances such as rubber, the solution must be handled in apparatus entirely of glass or other suitably inert material. It should be frequently restandardized. Store in glass-stoppered, amber-colored bottles.

$$N = \frac{g \text{ Na}_2\text{C}_2\text{O}_4}{\text{mL KMnO}_4 \text{ solution} \times 0.06700}$$

Potassium Thiocyanate, Tenth-Normal (0.1 N)

KSCN, 97.18

9.72 g in 1000 mL

Weigh exactly 9.72 g of potassium thiocyanate, previously dried for 2 hours at 110°, transfer to a 1-L volumetric flask, dilute with water to volume, and mix well. Standardize as follows: transfer 40.0 mL of freshly standardized 0.1 N silver nitrate VS to a 250-mL Erlenmeyer flask; and add 100 mL of water, 1 mL of nitric acid, and 2 mL of ferric ammonium sulfate TS. Titrate with the potassium thiocyanate solution, with agitation, to a permanent light pinkish-brown color of the supernatant.

$$N = \frac{\text{mL} \times N \text{ AgNO}_3}{\text{mL KSCN}}$$

Silver Nitrate, Tenth-Normal (0.1 N)

AgNO₃, 169.87

16.99 g in 1000 mL

Dissolve about 17.5 g of silver nitrate in 1000 mL of water, and standardize the solution as follows.

Transfer about 100 mg, accurately weighed, of reagent-grade sodium chloride, previously dried at 110° for 2 hours, to a 150-mL beaker, dissolve in 5 mL of water, and add 5 mL of acetic acid, 50 mL of methanol, and about 0.5 mL of eosin Y TS. Stir, preferably with a magnetic stirrer, and titrate with the silver nitrate solution.

$$N = \frac{\text{mg NaCl}}{\text{mL AgNO}_3 \times 58.44}$$

Sodium Arsenite, Twentieth-Molar (0.05 M)

NaAsO₂, 129.91

6.496 g in 1000 mL

Transfer 4.9455 g of arsenic trioxide, which has been pulverized and dried at 100° to constant weight, to a 1000-mL volumetric flask, dissolve it in 40 mL of 1 N sodium hydroxide, and add 1 N sulfuric acid or 1 N hydrochloric acid until the solution is neutral or only slightly acid to litmus. Add 30 g of sodium bicarbonate, dilute with water to volume, and mix.

Sodium Hydroxide, Alcoholic, Tenth-Normal (0.1 N)

NaOH, 40.00

To 250 mL of alcohol add 2 mL of a 50% (w/v) solution of sodium hydroxide.

Dissolve about 200 mg of benzoic acid, accurately weighed, in 10 mL of alcohol and 2 mL of water. Add 2 drops of phenolphthalein TS, and titrate with the alcoholic sodium hydroxide solution until a permanent pale pink color is produced.

$$N = \frac{\text{mg benzoic acid}}{122.1 \times \text{mL sodium hydroxide}}$$

Sodium Hydroxide, Normal (1 N)

NaOH, 40.00

40.00 g in 1000 mL

Dissolve 162 g of sodium hydroxide in 150 mL of carbon dioxide-free water, cool the solution to room temperature, and filter through hardened filter paper. Transfer 54.5 mL of the clear filtrate to a tight, polyolefin container, and dilute with carbon dioxide-free water to 1000 mL.

Accurately weigh about 5 g of potassium biphthalate, previously crushed lightly and dried at 120° for 2 hours, and dissolve in 75 mL of carbon dioxide-free water. Add 2 drops of phenolphthalein TS, and titrate with the sodium hydroxide solution to the production of a permanent pink color. Each 204.22 mg of potassium biphthalate is equivalent to 1 mL of 1 N sodium hydroxide.

$$N = \frac{g \text{ KHC}_8\text{H}_4\text{O}_4}{0.20422 \times \text{mL NaOH solution}}$$

[NOTES—(1) Solutions of alkali hydroxides absorb carbon dioxide when exposed to air. They should be preserved in bottles having well-fitted, suitable stoppers, provided with a tube filled with a mixture of sodium hydroxide and lime (soda-lime tubes) so that air entering the container must pass through this tube, which will absorb the carbon dioxide. (2) Prepare solutions of lower concentration (e.g., 0.1 N, 0.01 N) by quantitatively diluting accurately measured volumes of the 1 N solution with sufficient carbon dioxide-free water to yield the desired concentration.]

Restandardize the solution frequently.

Sodium Methoxide, Half-Normal (0.5 N) in Methanol

CH_3ONa , 54.02
27.01 g in 1000 mL

Weigh 11.5 g of freshly cut sodium metal, and cut into small cubes. Place about 0.5 mL of anhydrous methanol in a round-bottom, 250-mL flask equipped with a ground-glass joint, add 1 cube of the sodium metal, and, when the reaction has ceased, add the remaining sodium metal to the flask. Connect a water-jacketed condenser to the flask, and slowly add 250 mL of anhydrous methanol, in small portions, through the top of the condenser. Regulate the addition of the methanol so that the vapors are condensed and do not escape through the top of the condenser. After addition of the methanol is complete, connect a drying tube to the top of the condenser, and allow the solution to cool. Transfer the solution to a 1-L volumetric flask, dilute with anhydrous methanol to volume, and mix. Standardize the solution as follows.

Accurately measure about 20 mL of freshly standardized 1 N hydrochloric acid VS into a 250-mL conical flask, add 0.25 mL of phenolphthalein TS, and titrate with the sodium methoxide solution to the first appearance of a permanent pink color.

$$N = \frac{\text{mL HCl} \times N \text{ HCl}}{\text{mL sodium methoxide}}$$

Sodium Methoxide, Tenth-Normal (0.1 N) in Toluene

CH_3ONa , 54.02
5.402 g in 1000 mL

Cool in ice-water 150 mL of methanol contained in a 1000-mL volumetric flask, and add, in small portions, about 2.5 g of freshly cut sodium metal. When the metal has dissolved, add toluene to make 1000 mL, and mix. Store preferably in the reservoir of an automatic delivery buret suitably protected from carbon dioxide and moisture. Standardize the solution as follows.

Accurately weigh about 400 mg of primary standard benzoic acid, and dissolve in 80 mL of dimethylformamide in a flask. Add 3 drops of a 1 in 100 solution of thymol blue in dimethylformamide, and titrate with the sodium methoxide to a blue endpoint. Correct for the volume of the sodium methoxide solution consumed by 80 mL of the dimethylformamide. Each 12.21 mg of benzoic acid is equivalent to 1 mL of 0.1 N sodium methoxide.

$$N = \frac{\text{mg benzoic acid}}{122.1 \times \text{mL sodium methoxide (corrected for the blank)}}$$

[NOTES—(1) To eliminate any turbidity that may form following dilution with toluene, add methanol (25 to 30 mL usually suffices) until the solution is clear. (2) Restandardize the solution frequently.]

Sodium Nitrite, Tenth-Molar (0.1 M)

NaNO_2 , 69.00
6.900 g in 1000 mL

Dissolve 7.5 g of sodium nitrite in water to make 1000 mL, and standardize the solution as follows.

Accurately weigh about 500 mg of USP Sulfanilamide RS, previously dried at 105° for 3 hours, and transfer to a suitable beaker. Add 20 mL of hydrochloric acid and 50 mL of water, stir until dissolved, and cool to 15°. Maintaining the temperature at about 15°, titrate slowly with the sodium nitrite solution, placing the buret tip below the surface of the solution to preclude air oxidation of the sodium nitrite, and stir the solution gently with a magnetic stirrer, but avoid pulling a vortex of air beneath the surface. Use the indicator specified in the individual monograph, or, if a potentiometric procedure is specified, determine the endpoint electrometrically, using platinum–calomel or platinum–platinum electrodes. When the titration is within

1 mL of the endpoint, add the titrant in 0.1-mL portions, and allow 1 minute between additions. Each 17.22 mg of sulfanilamide is equivalent to 1 mL of 0.1000 M sodium nitrite.

$$M = \frac{\text{mg of sulfanilamide}}{172.22 \times \text{mL NaNO}_2}$$

Sodium Tetraphenylboron, Fiftieth-Molar (0.02 M)

$\text{NaB}(\text{C}_6\text{H}_5)_4$, 342.22
6.845 g in 1000 mL

Dissolve an amount of sodium tetraphenylboron, equivalent to 6.845 g of $\text{NaB}(\text{C}_6\text{H}_5)_4$, in water to make 1000 mL, and standardize the solution as follows.

Pipet two 75-mL portions of the solution into separate beakers, and to each add 1 mL of acetic acid and 25 mL of water. To each beaker add, slowly and with constant stirring, 25 mL of potassium biphthalate solution (1 in 20), and allow to stand for 2 hours. Filter one of the mixtures through a filtering crucible, and wash the precipitate with cold water. Transfer the precipitate to a container, add 50 mL of water, shake intermittently for 30 minutes, filter, and use the filtrate as the saturated potassium tetraphenylborate solution in the following standardization procedure. Filter the second mixture through a tared filtering crucible, and wash the precipitate with three 5-mL portions of saturated potassium tetraphenylborate solution. Dry the precipitate at 105° for 1 hour. Each g of potassium tetraphenylborate (KTPB) is equivalent to 955.1 mg of sodium tetraphenylboron.

$$M = \frac{\text{g KTPB} \times 0.9551}{342.22 \times 0.075}$$

[NOTE—Prepare this solution just before use.]

Sodium Thiosulfate, Tenth-Normal (0.1 N)

$\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$, 248.19
24.82 g in 1000 mL

Dissolve about 26 g of sodium thiosulfate and 200 mg of sodium carbonate in 1000 mL of recently boiled and cooled water. Standardize the solution as follows.

Accurately weigh about 210 mg of primary standard potassium dichromate, previously pulverized and dried according to the instructions on its label, if necessary, and dissolve in 100 mL of water in a glass-stoppered, 500-mL flask. Swirl to dissolve the solid, remove the stopper, and quickly add 3 g of potassium iodide, 2 g of sodium bicarbonate, and 5 mL of hydrochloric acid. Insert the stopper gently in the flask, swirl to mix, and allow to stand in the dark for exactly 10 minutes. Rinse the stopper and the inner walls of the flask with water, and titrate the liberated iodine with the sodium thiosulfate solution until the solution is yellowish green in color. Add 3 mL of starch TS, and continue the titration until the blue color is discharged. Perform a blank determination.

Restandardize the solution as frequently as supported by laboratory stability data. In the absence of such data, restandardize the solution weekly.

$$N = \frac{\text{mg K}_2\text{Cr}_2\text{O}_7}{49.04 \times \text{mL Na}_2\text{S}_2\text{O}_3}$$

Sulfuric Acid, Half-Normal (0.5 N) in Alcohol

H_2SO_4 , 98.08
24.52 g in 1000 mL

Add slowly, with stirring, 13.9 mL of sulfuric acid to a sufficient quantity of dehydrated alcohol to make 1000 mL.

Cool, and standardize against tromethamine as described under *Hydrochloric Acid, Half-Normal (0.5 N) in Methanol*.

$$N = \frac{\text{mg tromethamine}}{121.14 \times \text{mL H}_2\text{SO}_4}$$

Sulfuric Acid, Normal (1 N)

H_2SO_4 , **98.08**
49.04 g in 1000 mL

Add slowly, with stirring, 27 mL of sulfuric acid to a sufficient quantity of water to make 1000 mL. Cool and standardize against tromethamine as described under *Hydrochloric Acid, Normal (1 N)*.

Tetrabutylammonium Hydroxide, Tenth-Normal (0.1 N)

$(\text{C}_4\text{H}_9)_4\text{NOH}$, **259.47**
25.95 g in 1000 mL

Dissolve 40 g of tetra-*n*-butylammonium iodide in 90 mL of anhydrous methanol in a glass-stoppered flask. Place in an ice bath, add 20 g of powdered silver oxide, insert the stopper in the flask, and agitate vigorously for 60 minutes. Centrifuge a few mL, and test the supernatant for iodide (see *Iodide* (191)). If the test is positive, add an additional 2 g of silver oxide, and continue to allow to stand for 30 minutes with intermittent agitation. When all of the iodide has reacted, filter through a fine-porosity, sintered-glass funnel. Rinse the flask and the funnel with three 50-mL portions of anhydrous toluene, adding the rinsings to the filtrate. Dilute with a mixture of three volumes of anhydrous toluene and 1 volume of anhydrous methanol to 1000 mL, and flush the solution for 10 minutes with dry, carbon dioxide-free nitrogen. [NOTE—If necessary to obtain a clear solution, further small quantities of anhydrous methanol may be added.] Store in a reservoir protected from carbon dioxide and moisture, and discard after 60 days. Alternatively, the solution may be prepared by diluting a suitable volume of commercially available tetrabutylammonium hydroxide solution in methanol with a mixture of 4 volumes of anhydrous toluene and 1 volume of anhydrous methanol. [NOTE—If necessary to obtain a clear solution, further small quantities of methanol may be added.]

Standardize the solution on the day of use as follows.

Dissolve about 400 mg of primary standard benzoic acid, accurately weighed, in 80 mL of dimethylformamide, add 3 drops of a 1 in 100 solution of thymol blue in dimethylformamide, and titrate to a blue endpoint with the tetrabutylammonium hydroxide solution, delivering the titrant from a buret equipped with a carbon dioxide absorption trap. Perform a blank determination, and make any necessary correction. Each mL of 0.1 N tetrabutylammonium hydroxide is equivalent to 12.21 mg of benzoic acid.

$$N = \frac{\text{mg benzoic acid}}{122.1 \times \text{mL } (\text{C}_4\text{H}_9)_4\text{NOH}}$$

**Tetrabutylammonium Hydroxide in Methanol/
Isopropyl Alcohol, 0.1 N**

Prepare as described for *Tetrabutylammonium Hydroxide, Tenth-Normal (0.1 N)* using isopropyl alcohol instead of toluene, and standardize as described. Alternatively, the solution may be prepared by diluting a suitable volume of commercially available tetrabutylammonium hydroxide solution in methanol with 4 volumes of anhydrous isopropyl alcohol.

$$N = \frac{\text{mg benzoic acid}}{122.1 \times \text{mL } (\text{C}_4\text{H}_9)_4\text{NOH}}$$

Tetramethylammonium Bromide, Tenth-Molar (0.1 M)

$(\text{CH}_3)_4\text{NBr}$, **154.05**
15.41 g in 1000 mL

Dissolve 15.41 g of tetramethylammonium bromide in water to make 1000 mL, and standardize the solution as follows.

Transfer an accurately measured volume of about 40 mL of the solution to a beaker, add 10 mL of diluted nitric acid and 50.0 mL of 0.1 N silver nitrate VS, and mix. Add 2 mL of ferric ammonium sulfate TS, and titrate the excess silver nitrate with 0.1 N ammonium thiocyanate VS.

$$M = \frac{\text{mL AgNO}_3 \times N \text{ AgNO}_3}{\text{mL } (\text{CH}_3)_4\text{NBr}}$$

Tetramethylammonium Chloride, Tenth-Molar (0.1 M)

$(\text{CH}_3)_4\text{NCl}$, **109.60**
10.96 g in 1000 mL

Dissolve 10.96 g of tetramethylammonium chloride in water to make 1000 mL, and standardize the solution as follows.

Transfer an accurately measured volume of about 40 mL of the solution to a flask, add 10 mL of diluted nitric acid and 50.0 mL of 0.1 N silver nitrate VS, and mix. Add 5 mL of nitrobenzene and 2 mL of ferric ammonium sulfate TS, shake, and titrate the excess silver nitrate with 0.1 N ammonium thiocyanate VS.

$$M = \frac{\text{mL AgNO}_3 \times N \text{ AgNO}_3}{\text{mL } (\text{CH}_3)_4\text{NCl}}$$

Titanium Trichloride, Tenth-Normal (0.1 N)

TiCl_3 , **154.23**
15.42 g in 1000 mL

Add 75 mL of titanium trichloride solution (1 in 5) to 75 mL of hydrochloric acid, dilute to 1000 mL, and mix. Standardize the solution as follows, using the special titration apparatus described.

Apparatus—Store the titanium trichloride solution in the reservoir of a closed-system titration apparatus in an atmosphere of hydrogen.

Use a wide-mouth, 500-mL conical flask as the titration vessel, and connect it by means of a tight-fitting rubber stopper to the titration buret, an inlet tube for carbon dioxide, and an exit tube. Arrange for mechanical stirring. All joints must be air-tight. Arrange to have both the hydrogen and the carbon dioxide pass through wash bottles containing titanium trichloride solution (approximately 1 in 50) to remove any oxygen.

If the solution to be titrated is to be heated before or during titration, connect the titration flask with an upright reflux condenser through the rubber stopper.

Standardization—Place an accurately measured volume of about 40 mL of 0.1 N ferric ammonium sulfate VS in the titration flask, and pass in a rapid stream of carbon dioxide until all the air has been removed. Add the titanium trichloride solution from the buret until near the calculated endpoint (about 35 mL), then add through the outlet tube 5 mL of ammonium thiocyanate TS, and continue the titration until the solution is colorless.

$$N = \frac{\text{mL FeNH}_4(\text{SO}_4)_2 \times N \text{ FeNH}_4(\text{SO}_4)_2}{\text{mL TiCl}_3}$$

Zinc Sulfate, Twentieth-Molar (0.05 M)

$\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$, **287.56**
14.4 g in 1000 mL

Dissolve 14.4 g of zinc sulfate in water to make 1 L. Standardize the solution as follows.

Accurately measure about 10 mL of 0.05 M edetate disodium VS into a 125-mL conical flask, and add, in the order given, 10 mL of acetic acid–ammonium acetate buffer TS,

50 mL of alcohol, and 2 mL of dithizone TS. Titrate with the zinc sulfate solution to a clear, rose-pink color.

$$M = \frac{\text{mL edetate disodium} \times M \text{ edetate disodium}}{\text{mL ZnSO}_4}$$

Chromatographic Columns

The following list of packings (L), phases (G), and supports (S) is intended to be a convenient reference for the chromatographer. [NOTE—Particle sizes given in this listing are those generally provided. Where other, usually finer, sizes are required, the individual monograph specifies the desired particle size. Within any category of packings or phases listed below, there may be a wide range of columns available. Where it is necessary to define more specifically the chromatographic conditions, the individual monograph so indicates.]

Packings

L1—Octadecyl silane chemically bonded to porous or nonporous silica or ceramic microparticles, 1.5 to 10 µm in diameter, or a monolithic silica rod.

L2—Octadecyl silane chemically bonded to silica gel of a controlled surface porosity that has been bonded to a solid spherical core, 30 to 50 µm in diameter.

L3—Porous silica particles, 1.5 to 10 µm in diameter, or a monolithic silica rod.

L4—Silica gel of controlled surface porosity bonded to a solid spherical core, 30 to 50 µm in diameter.

L5—Alumina of controlled surface porosity bonded to a solid spherical core, 30 to 50 µm in diameter.

L6—Strong cation-exchange packing—sulfonated fluorocarbon polymer coated on a solid spherical core, 30 to 50 µm in diameter.

L7—Octylsilane chemically bonded to totally porous or superficially porous silica particles, 1.5–10 µm in diameter, or a monolithic silica rod.

L8—An essentially monomolecular layer of aminopropylsilane chemically bonded to totally porous silica gel support, 1.5 to 10 µm in diameter.

L9—Irregular or spherical, totally porous silica gel having a chemically bonded, strongly acidic cation-exchange coating, 3 to 10 µm in diameter.

L10—Nitrile groups chemically bonded to porous silica particles, 1.5 to 10 µm in diameter.

L11—Phenyl groups chemically bonded to porous silica particles, 1.5 to 10 µm in diameter.

L12—A strong anion-exchange packing made by chemically bonding a quaternary amine to a solid silica spherical core, 30 to 50 µm in diameter.

L13—Trimethylsilane chemically bonded to porous silica particles, 3 to 10 µm in diameter.

L14—Silica gel having a chemically bonded, strongly basic quaternary ammonium anion-exchange coating, 5 to 10 µm in diameter.

L15—Hexylsilane chemically bonded to totally porous silica particles, 3 to 10 µm in diameter.

L16—Dimethylsilane chemically bonded to porous silica particles, 5 to 10 µm in diameter.

L17—Strong cation-exchange resin consisting of sulfonated cross-linked styrene–divinylbenzene copolymer in the hydrogen form, 6 to 12 µm in diameter.

L18—Amino and cyano groups chemically bonded to porous silica particles, 3 to 10 µm in diameter.

L19—Strong cation-exchange resin consisting of sulfonated cross-linked styrene–divinylbenzene copolymer in the calcium form, about 9 µm in diameter.

L20—Dihydroxypropane groups chemically bonded to porous silica or hybrid particles, 1.5 to 10 µm in diameter.

L21—A rigid, spherical styrene–divinylbenzene copolymer 3 to 10 µm in diameter.

L22—A cation-exchange resin made of porous polystyrene gel with sulfonic acid groups, about 10 µm in size.

L23—An anion-exchange resin made of porous polymethacrylate or polyacrylate gel with quaternary ammonium groups, 7–12 µm in size.

L24—A semi-rigid hydrophilic gel consisting of vinyl polymers with numerous hydroxyl groups on the matrix surface, 32 to 63 µm in diameter. [NOTE—Available as YMC-Pack PVA-SIL manufactured by YMC Co., Ltd. and distributed by Waters Corp. (www.waters.com).]

L25—Packing having the capacity to separate compounds with a molecular weight range from 100–5000 (as determined by polyethylene oxide), applied to neutral, anionic, and cationic water-soluble polymers. A polymethacrylate resin base, cross-linked with polyhydroxylated ether (surface contained some residual carboxyl functional groups) was found suitable.

L26—Butyl silane chemically bonded to totally porous silica particles, 1.5 to 10 µm in diameter.

L27—Porous silica particles, 30 to 50 µm in diameter.

L28—A multifunctional support, which consists of a high purity, 100 Å, spherical silica substrate that has been bonded with anionic exchanger, amine functionality in addition to a conventional reversed phase C8 functionality.

L29—Gamma alumina, reverse-phase, low carbon percentage by weight, alumina-based polybutadiene spherical particles, 5 µm in diameter with a pore volume of 80 Å.

L30—Ethyl silane chemically bonded to totally porous silica particles, 3 to 10 µm in diameter.

L31—A hydroxide-selective, strong anion-exchange resin—quaternary amine bonded on latex particles attached to a core of 8.5-µm macroporous particles having a pore size of 2000 Å and consisting of ethylvinylbenzene cross-linked with 55% divinylbenzene.

L32—A chiral ligand-exchange packing—L-proline copper complex covalently bonded to irregularly shaped silica particles, 5 to 10 µm in diameter.

L33—Packing having the capacity to separate dextrans by molecular size over a range of 4,000 to 500,000 Da. It is spherical, silica-based, and processed to provide pH stability. [NOTE—Available as TSK-GEL G4000SWxl from Tosoh Bioscience (www.tosohbioscience.com).]

L34—Strong cation-exchange resin consisting of sulfonated cross-linked styrene–divinylbenzene copolymer in the lead form, 7 to 9 µm in diameter.

L35—A zirconium-stabilized spherical silica packing with a hydrophilic (diol-type) molecular monolayer bonded phase having a pore size of 150 Å.

L36—A 3,5-dinitrobenzoyl derivative of L-phenylglycine covalently bonded to 5-µm aminopropyl silica.

L37—Packing having the capacity to separate proteins by molecular size over a range of 2,000 to 40,000 Da. It is a polymethacrylate gel.

L38—A methacrylate-based size-exclusion packing for water-soluble samples.

L39—A hydrophilic polyhydroxymethacrylate gel of totally porous spherical resin.

L40—Cellulose tris-3,5-dimethylphenylcarbamate coated porous silica particles, 5 to 20 μm in diameter.

L41—Immobilized α_1 -acid glycoprotein on spherical silica particles, 5 μm in diameter.

L42—Octylsilane and octadecylsilane groups chemically bonded to porous silica particles, 5 μm in diameter.

L43—Pentafluorophenyl groups chemically bonded to silica particles by a propyl spacer, 1.5 to 10 μm in diameter.

L44—A multifunctional support, which consists of a high purity, 60 Å, spherical silica substrate that has been bonded with a cationic exchanger, sulfonic acid functionality in addition to a conventional reversed phase C8 functionality.

L45—Beta cyclodextrin bonded to porous silica particles, 5 to 10 μm in diameter.

L46—Polystyrene/divinylbenzene substrate agglomerated with quaternary amine functionalized latex beads, about 9 to 11 μm in diameter.

L47—High-capacity anion-exchange microporous substrate, fully functionalized with trimethylamine groups, 8 μm in diameter. [NOTE—Available as CarboPac MA1 and distributed by Dionex Corp. (www.dionex.com).]

L48—Sulfonated, cross-linked polystyrene with an outer layer of submicron, porous, anion-exchange microbeads, 10 to 15 μm in diameter.

L49—A reversed-phase packing made by coating a thin layer of polybutadiene onto spherical porous zirconia particles, 3 to 10 μm in diameter. [NOTE—Available as Zirchrom PBD from www.zirchrom.com.]

L50—Multifunction resin with reversed-phase retention and strong anion-exchange functionalities. The resin consists of ethylvinylbenzene, 55% cross-linked with divinylbenzene copolymer, 3 to 15 μm in diameter, and a surface area not less than 350 m^2 per g. Substrate is coated with quaternary ammonium functionalized latex particles consisting of styrene cross-linked with divinylbenzene. [NOTE—Available as OmniPac PAX-500 and distributed by Dionex Corp. (www.dionex.com).]

L51—Amylose tris-3,5-dimethylphenylcarbamate-coated, porous, spherical, silica particles, 5 to 10 μm in diameter. [NOTE—Available as Chiralpak AD from Chiral Technologies, Inc., (www.chiraltech.com).]

L52—A strong cation-exchange resin made of porous silica with sulfopropyl groups, 5 to 10 μm in diameter. [NOTE—Available as TSK-GEL IC-Cation-SW from Tosoh Bioscience (www.tosohbioscience.com).]

L53—Weak cation-exchange resin consisting of ethylvinylbenzene, 55% cross-linked with divinylbenzene copolymer, 3 to 15 μm diameter. Substrate is surface grafted with carboxylic acid and/or phosphoric acid functionalized monomers. Capacity not less than 500 μEq /column. [NOTE—Available as IonPac CS14 distributed by Dionex Corp. (www.dionex.com).]

L54—A size exclusion medium made of covalent bonding of dextran to highly cross-linked porous agarose beads, about 13 μm in diameter.

[NOTE—Available as Superdex Peptide HR 10/30 from www.gelifesciences.com.]

L55—A strong cation-exchange resin made of porous silica coated with polybutadiene-maleic acid copolymer, about 5 μm in diameter. [NOTE—Available as IC-Pak C M/D from Waters Corp. (www.waters.com).]

L56—Propyl silane chemically bonded to totally porous silica particles, 3 to 10 μm in diameter. [NOTE—Available as Zorbax SB-C3 from Agilent Technologies (www.agilent.com/chem).]

L57—A chiral-recognition protein, ovomucoid, chemically bonded to silica particles, about 5 μm in diameter, with a pore size of 120 Å. [NOTE—Available as Ultron ES-OVM from Agilent Technologies (www.agilent.com/chem).]

L58—Strong cation-exchange resin consisting of sulfonated cross-linked styrene-divinylbenzene copolymer in

the sodium form, about 6 to 30 μm in diameter. [NOTE—Available as Aminex HPX-87N from Bio-Rad Laboratories, (2000/01 catalog, #125-0143) www.bio-rad.com.]

L59—Packing for the size-exclusion separation of proteins (separation by molecular weight) over the range of 5 to 7000 kDa. The packing is a spherical 1.5- to 10- μm silica or hybrid packing with a hydrophilic coating.

L60—Spherical, porous silica gel, 10 μm or less in diameter, the surface of which has been covalently modified with alkyl amide groups and endcapped. [NOTE—Available as Supelcosil LC-ABZ from Supelco (www.sigmaaldrich.com/supelco).]

L61—A hydroxide selective strong anion-exchange resin consisting of a highly cross-linked core of 13- μm microporous particles having a pore size less than 10 Å units and consisting of ethylvinylbenzene cross-linked with 55% divinylbenzene with a latex coating composed of 85-nm diameter microbeads bonded with alkanol quaternary ammonium ions (6%). [NOTE—Available as Ion Pac AS-11 and AG-11 from Dionex (www.dionex.com).]

L62—C30 silane bonded phase on a fully porous spherical silica, 3 to 15 μm in diameter.

L63—Glycopeptide teicoplanin linked through multiple covalent bonds to a 100-Å units spherical silica. [NOTE—Available as Astec Chirobiotic T from Supelco (www.sigmaaldrich.com).]

L64—Strongly basic anion-exchange resin consisting of 8% cross-linked styrene-divinylbenzene copolymer with a quaternary ammonium group in the chloride form, 45 to 180 μm in diameter. [NOTE—A suitable grade is available as AG 1-X8 resin chloride form from www.discover.bio-rad.com.]

L65—Strongly acidic cation-exchange resin consisting of 8% sulfonated cross-linked styrene-divinylbenzene copolymer with a sulfonic acid group in the hydrogen form, 45 to 250 μm in diameter. [NOTE—A suitable grade is available as AG 50W-X2 resin hydrogen form from www.discover.bio-rad.com.]

L66—A crown ether coated on a 5- μm particle size silica gel substrate. The active site is (S)-18-crown-6-ether. [NOTE—Available as Crownpak CR(+) from Daicel (www.daicel.com).]

L67—Porous vinyl alcohol copolymer with a C18 alkyl group attached to the hydroxyl group of the polymer, 2 to 10 μm in diameter. [NOTE—Available as apHera C18 from Supelco (www.sigmaaldrich.com).]

L68—Spherical, porous silica, 10 μm or less in diameter, the surface of which has been covalently modified with alkyl amide groups and not endcapped. [NOTE—Available as SUPELCOSIL SUPLEX pKb-100 from Supelco (www.sigmaaldrich.com).]

L69—Ethylvinylbenzene/divinylbenzene substrate agglomerated with quaternary amine functionalized 130-nm latex beads, about 6.5 μm in diameter. [NOTE—Available as CarboPac PA20 from www.dionex.com.]

L70—Cellulose tris(phenyl carbamate) coated on 5- μm silica. [NOTE—Available as Chiralcel OC-H from www.chiraltech.com.]

L71—A rigid, spherical polymetacrylate, 4 to 6 μm in diameter. [NOTE—Available as RSpak DE-613 from www.shodex.com.]

L72—(S)-phenylglycine and 3,5-dinitroaniline urea linkage covalently bonded to silica.

[NOTE—Available as Sumichiral OA-3300, distributed by www.phenomenex.com.]

L73—A rigid spherical polydivinylbenzene particle, 5 to 10 μm in diameter. [NOTE—Available as Jordi-Gel DBV from www.jordiflp.com.]

L74—A strong anion-exchange resin consisting of a highly cross-linked core of 7- μm macroporous particles having a 100-Å average pore size and consisting of ethylvinylbenzene cross-linked with 55% divinylbenzene and an anion-exchange layer grafted to the surface, which is functionalized with alkyl quaternary ammonium ions. [NOTE—Available as IonPac AS14A from Dionex (www.dionex.com).]

L75—A chiral-recognition protein, bovine serum albumine (BSA), chemically bonded to silica particles, about 7 µm in diameter, with a pore size of 300 Å.

Phases

- G1**—Dimethylpolysiloxane oil.
G2—Dimethylpolysiloxane gum.
G3—50% Phenyl-50% methylpolysiloxane.
G4—Diethylene glycol succinate polyester.
G5—3-Cyanopropylpolysiloxane.
G6—Trifluoropropylmethylpolysiloxane.
G7—50% 3-Cyanopropyl-50% phenylmethylsilicone.
G8—80% Bis(3-cyanopropyl)-20% 3-cyanopropylphenylpolysiloxane (percentages refer to molar substitution).
G9—Methylvinylpolysiloxane.
G10—Polyamide formed by reacting a C₃₆ dicarboxylic acid with 1,3-di-4-piperidylpropane and piperidine in the respective mole ratios of 1.00:0.90:0.20.
G11—Bis(2-ethylhexyl) sebacate polyester.
G12—Phenyldiethanolamine succinate polyester.
G13—Sorbitol.
G14—Polyethylene glycol (av. mol. wt. of 950 to 1050).
G15—Polyethylene glycol (av. mol. wt. of 3000 to 3700).
G16—Polyethylene glycol compound (av. mol. wt. about 15,000). A high molecular weight compound of polyethylene glycol with a diepoxide linker. [NOTE—Available commercially as Polyethylene Glycol Compound 20M, or as Carbowax 20M, from suppliers of chromatographic reagents.]
G17—75% Phenyl-25% methylpolysiloxane.
G18—Polyalkylene glycol.
G19—25% Phenyl-25% cyanopropyl-50% methylsilicone.
G20—Polyethylene glycol (av. mol. wt. of 380 to 420).
G21—Neopentyl glycol succinate.
G22—Bis(2-ethylhexyl) phthalate.
G23—Polyethylene glycol adipate.
G24—Diisodecyl phthalate.
G25—Polyethylene glycol compound TPA. A high molecular weight compound of a polyethylene glycol and a diepoxide that is esterified with terephthalic acid.
 [NOTE—Available commercially as Carbowax 20M-TPA from suppliers of chromatographic reagents.]
G26—25% 2-Cyanoethyl-75% methylpolysiloxane.
G27—5% Phenyl-95% methylpolysiloxane.
G28—25% Phenyl-75% methylpolysiloxane.
G29—3,3'-Thiodipropionitrile.
G30—Tetraethylene glycol dimethyl ether.
G31—Nonylphenoxypoly(ethyleneoxy)ethanol (av. ethyleneoxy chain length is 30); Nonoxynol 30.
G32—20% Phenylmethyl-80% dimethylpolysiloxane.
G33—20% Carborane-80% methylsilicone.
G34—Diethylene glycol succinate polyester stabilized with phosphoric acid.
G35—A high molecular weight compound of a polyethylene glycol and a diepoxide that is esterified with nitroterephthalic acid.
G36—1% Vinyl-5% phenylmethylpolysiloxane.
G37—Polyimide.
G38—Phase G1 containing a small percentage of a tailing inhibitor.
 [NOTE—A suitable grade is available commercially as "SP2100/0.1% Carbowax 1500" from Supelco, Inc. (www.sigmaaldrich.com/supelco).]

G39—Polyethylene glycol (av. mol. wt. about 1500).

G40—Ethylene glycol adipate.

G41—Phenylmethyldimethylsilicone (10% phenyl-substituted).

G42—35% phenyl-65% dimethylpolysiloxane (percentages refer to molar substitution).

G43—6% cyanopropylphenyl-94% dimethylpolysiloxane (percentages refer to molar substitution).

G44—2% low molecular weight petrolatum hydrocarbon grease and 1% solution of potassium hydroxide.

G45—Divinylbenzene-ethylene glycol-dimethylacrylate.

G46—14% Cyanopropylphenyl-86% methylpolysiloxane.

G47—Polyethylene glycol (av. mol. wt. of about 8000).

G48—Highly polar, partially cross-linked cyanopolysiloxane.

Supports

[NOTE—Unless otherwise specified, mesh sizes of 80 to 100 or, alternatively, 100 to 120 are intended.]

S1A—Siliceous earth for gas chromatography has been flux-calcined by mixing diatomite with Na₂CO₃ flux and calcining above 900°. The siliceous earth is acid-washed, then water-washed until neutral, but not base-washed. The siliceous earth may be silanized by treating with an agent such as dimethyldichlorosilane [NOTE—Unless otherwise specified in the individual monograph, silanized support is intended.] to mask surface silanol groups.

S1AB—The siliceous earth as described above is both acid- and base-washed. [NOTE—Unless otherwise specified in the individual monograph, silanized support is intended.]

S1C—A support prepared from crushed firebrick and calcined or burned with a clay binder above 900° with subsequent acid-wash. It may be silanized.

S1NS—The siliceous earth is untreated.

S2—Styrene-divinylbenzene copolymer having a nominal surface area of less than 50 m² per g and an average pore diameter of 0.3 to 0.4 µm.

S3—Copolymer of ethylvinylbenzene and divinylbenzene having a nominal surface area of 500 to 600 m² per g and an average pore diameter of 0.0075 µm.

S4—Styrene-divinylbenzene copolymer with aromatic -O and -N groups, having a nominal surface area of 400 to 600 m² per g and an average pore diameter of 0.0076 µm.

S5—40- to 60-mesh, high-molecular weight tetrafluorethylene polymer.

S6—Styrene-divinylbenzene copolymer having a nominal surface area of 250 to 350 m² per g and an average pore diameter of 0.0091 µm.

S7—Graphitized carbon having a nominal surface area of 12 m² per g.

S8—Copolymer of 4-vinyl-pyridine and styrene-divinylbenzene.

S9—A porous polymer based on 2,6-diphenyl-*p*-phenylene oxide.

S10—A highly polar cross-linked copolymer of acrylonitrile and divinylbenzene.

S11—Graphitized carbon having a nominal surface area of 100 m² per g modified with small amounts of petrolatum and polyethylene glycol compound.

S12—Graphitized carbon having a nominal surface area of 100 m² per g.

Reference Tables

CONTAINERS FOR DISPENSING CAPSULES AND TABLETS

The following table is provided as a reminder for the pharmacist engaged in the typical dispensing situation who already is acquainted with the *Packaging and Storage* requirements set forth in the individual monographs. It lists the capsules and tablets that are official in the *United States Pharmacopeia* and indicates the relevant tight (T), well-closed (W), and light-resistant (LR) specifications applicable to containers in which the drug that is repackaged should be dispensed.

This table is not intended to replace, nor should it be interpreted as replacing, the definitive requirements stated in the individual monographs.

Container Specifications for Capsules and Tablets

Monograph Title	Container Specification
Abacavir Tablets	W
Acebutolol Hydrochloride Capsules	T
Acepromazine Maleate Tablets	T, LR
Acetaminophen Capsules	T
Acetaminophen Tablets, Extended-Release	T
Acetaminophen Tablets	T
Acetaminophen and Aspirin Tablets	T
Acetaminophen, Aspirin, and Caffeine Tablets	T
Acetaminophen and Caffeine Tablets	T
Acetaminophen and Salts of Chlorpheniramine, Dextromethorphan, and Phenylpropanolamine, Capsules Containing at Least Three of the Following—	T
Acetaminophen and Salts of Chlorpheniramine, Dextromethorphan, and Phenylpropanolamine, Tablets Containing at Least Three of the Following—	T
Acetaminophen and Salts of Chlorpheniramine, Dextromethorphan, and Pseudoephedrine, Capsules Containing at Least Three of the Following—	T
Acetaminophen and Salts of Chlorpheniramine, Dextromethorphan, and Pseudoephedrine, Tablets Containing at Least Three of the Following—	T
Acetaminophen, Chlorpheniramine Maleate, and Dextromethorphan Hydrobromide Tablets	T
Acetaminophen and Codeine Phosphate Capsules	T, LR
Acetaminophen and Codeine Phosphate Tablets	T, LR
Acetaminophen and Diphenhydramine Citrate Tablets	T
Acetaminophen, Diphenhydramine Hydrochloride, and Pseudoephedrine Hydrochloride Tablets	T
Acetaminophen and Pseudoephedrine Hydrochloride Tablets	T
Acetaminophen and Tramadol Hydrochloride Tablets	T
Acetazolamide Tablets	T
Acetohexamide Tablets	W
Acetohydroxamic Acid Tablets	T
Acitretin Capsules	W, LR

Container Specifications for Capsules and Tablets (Continued)

Monograph Title	Container Specification
Acyclovir Capsules	T
Acyclovir Tablets	T
Albendazole Tablets	T
Albuterol Tablets	T, LR
Alendronate Sodium Tablets	T
Add the following:	
▲ Alfuzosin Hydrochloride Tablets, Extended-Release	LR▲ ^{USP36}
Allopurinol Tablets	W
Alprazolam Tablets	T, LR
Alprazolam Tablets, Extended-Release	T, LR
Alprazolam Tablets, Orally Disintegrating	T
Altretamine Capsules	T, LR
Alumina and Magnesia Tablets	W
Alumina, Magnesia, and Calcium Carbonate Tablets	W
Alumina, Magnesia, Calcium Carbonate, and Simethicone Tablets	W
Alumina, Magnesia, and Simethicone Tablets	W
Alumina and Magnesium Carbonate Tablets	T
Alumina, Magnesium Carbonate, and Magnesium Oxide Tablets	T
Alumina and Magnesium Trisilicate Tablets	W
Aluminum Carbonate Gel, Dried Basic, Capsules	W
Aluminum Carbonate Gel, Dried Basic, Tablets	W
Aluminum Hydroxide Gel, Dried, Capsules	W
Aluminum Hydroxide Gel, Dried, Tablets	W
Amantadine Hydrochloride Capsules	T
Amiloride Hydrochloride Tablets	W
Amiloride Hydrochloride and Hydrochlorothiazide Tablets	W
Aminobenzoate Potassium Capsules	W
Aminobenzoate Potassium Tablets	W
Aminocaproic Acid Tablets	T
Aminogluthethimide Tablets	T, LR
Aminopentamide Sulfate Tablets	W
Aminophylline Tablets	T
Aminophylline Tablets, Delayed-Release	T
Aminosalicylate Sodium Tablets	T, LR
Aminosalicylic Acid Tablets	T, LR
Amitriptyline Hydrochloride Tablets	W
Amlodipine Besylate Tablets	T, LR
Ammonium Chloride Tablets, Delayed-Release	T
Amodiaquine Hydrochloride Tablets	T
Amoxapine Tablets	W
Amoxicillin Capsules	T
Amoxicillin Tablets	T
Amoxicillin and Clavulanate Potassium Tablets	T
Amphetamine Sulfate Tablets	W
Ampicillin Capsules	T
Ampicillin Tablets	T
Anagrelide Capsules	T, LR
Anileridine Hydrochloride Tablets	T, LR
Apomorphine Hydrochloride Tablets	T, LR

DESCRIPTION AND SOLUBILITY

Description and Relative Solubility of USP and NF Articles

The "description" and "solubility" statements pertaining to an article (formerly included in the individual monograph) are general in nature. The information is provided for those who use, prepare, and dispense drugs, solely to indicate descriptive and solubility properties of an article complying with monograph standards. The properties are not in themselves standards or tests for purity even though they may indirectly assist in the preliminary evaluation of the integrity of an article.

Taste and Odor

Organoleptic characteristics are indicated in many instances because they may be useful and descriptive properties of substances. However, they are not meant to be applied as tests for identifying materials.

The inclusion of odor or taste among other descriptive properties may aid in identifying the causative agent following accidental exposure to or contact with a substance. This information is provided as a warning or to make an individual aware of sensations that may be encountered. The use of odor or taste as a test for identification or content is strongly discouraged.

The characteristic odor of a volatile substance becomes apparent immediately on opening a container of it. The odor may be agreeable (e.g., Peppermint Oil), unpleasant (e.g., Sulfur Dioxide), or potentially hazardous on prolonged exposure (e.g., Coal Tar). Moreover, an unexpected odor may be encountered if the characteristics of a substance are not known or if a container is incorrectly labeled. Consequently, containers of such substances should be opened cautiously, preferably in a well-ventilated fume hood. A characteristic taste or sensation produced in the oral cavity likewise is apparent if traces of residue materials on fingers are inadvertently brought into contact with the tongue or adjacent mucosal tissues.

Solubility

Only where a special, quantitative solubility test is given in the individual monograph, and is designated by a test heading, is it a test for purity.

The approximate solubilities of Pharmacopeial and National Formulary substances are indicated by the descriptive terms in the accompanying table. The term "miscible" as used in this Pharmacopeia pertains to a substance that yields a homogeneous mixture when mixed in any proportion with the designated solvent.

Descriptive Term	Parts of Solvent Required for 1 Part of Solute
Very soluble	Less than 1
Freely soluble	From 1 to 10
Soluble	From 10 to 30
Sparingly soluble	From 30 to 100
Slightly soluble	From 100 to 1000
Very slightly soluble	From 1000 to 10,000
Practically insoluble, or Insoluble	10,000 and over

Soluble Pharmacopeial and National Formulary articles, when brought into solution, may show traces of physical impurities, such as minute fragments of filter paper, fibers,

and other particulate matter, unless limited or excluded by definite tests or other specifications in the individual monographs.

Abacavir Sulfate: White to off-white powder. Soluble in water, in ethyl acetate, in absolute alcohol, and in methanol.

Acacia: Is practically odorless and produces a mucilaginous sensation on the tongue. Insoluble in alcohol. Optical rotation varies depending on the source of Acacia. For example, specific rotation values, calculated on the anhydrous basis and determined on a 1.0% (w/v) solution, usually are between -25° and -35° for *Acacia senegal* and between $+35^{\circ}$ and $+60^{\circ}$ for *Acacia seyal*. *NF category:* Emulsifying and/or solubilizing agent; suspending and/or viscosity-increasing agent; tablet binder.

Acebutolol Hydrochloride: White or almost white, crystalline powder. Soluble in alcohol and in water; very slightly soluble in acetone and in methylene chloride; practically insoluble in ether. Melts at about 141° to 144° .

Acesulfame Potassium: A white, crystalline powder or colorless crystals. Soluble in water; very slightly soluble in acetone and in alcohol. *NF category:* Sweetening agent.

Acetaminophen: White, odorless, crystalline powder, having a slightly bitter taste. Freely soluble in alcohol; soluble in boiling water and in 1 N sodium hydroxide.

Acetazolamide: White to faintly yellowish-white, crystalline, odorless powder. Sparingly soluble in practically boiling water; slightly soluble in alcohol; very slightly soluble in water.

Acetic Acid: Clear, colorless liquid, having a strong, characteristic odor, and a sharply acid taste. Specific gravity is about 1.045. Miscible with water, with alcohol, and with glycerin. *NF category:* Acidifying agent; buffering agent.

Glacial Acetic Acid: Clear, colorless liquid, having a pungent, characteristic odor and, when well diluted with water, an acid taste. Boils at about 118° . Specific gravity is about 1.05. Miscible with water, with alcohol, and with glycerin. *NF category:* Acidifying agent.

Acetohexamide: White, crystalline, practically odorless powder. Soluble in pyridine and in dilute solutions of alkali hydroxides; slightly soluble in alcohol and in chloroform; practically insoluble in water and in ether.

Acetohydroxamic Acid: White, slightly hygroscopic, crystalline powder. Melts, after drying at about 80° for 2 to 4 hours, at about 88° . Freely soluble in water and in alcohol; very slightly soluble in chloroform.

Acetone: Transparent, colorless, mobile, volatile liquid, having a characteristic odor. A solution (1 in 2) is neutral to litmus. Miscible with water, with alcohol, with ether, with chloroform, and with most volatile oils. *NF category:* Solvent.

Acetylcholine Chloride: White or off-white crystals or crystalline powder. Very soluble in water; freely soluble in alcohol; insoluble in ether. Is decomposed by hot water and by alkalies.

Acetylcysteine: White, crystalline powder, having a slight acetic odor. Freely soluble in water and in alcohol; practically insoluble in chloroform and in ether.

Acetyltributyl Citrate: Clear, practically colorless, oily liquid. Freely soluble in alcohol, in isopropyl alcohol, in acetone, and in toluene; insoluble in water. *NF category:* Plasticizer.

Acetyltriethyl Citrate: Clear, practically colorless, oily liquid. Freely soluble in alcohol, in isopropyl alcohol, in ace-

tone, and in toluene; insoluble in water. *NF category*: Plasticizer.

Acitretin: Yellow or greenish, crystalline powder. Sparingly soluble in tetrahydrofuran; slightly soluble in acetone and in alcohol; very slightly soluble in cyclohexane; practically insoluble in water.

Acyclovir: White to off-white, crystalline powder. Melts at temperatures higher than 250°, with decomposition. Soluble in diluted hydrochloric acid; slightly soluble in water; insoluble in alcohol.

Add the following:

• **Adapalene**: White or almost white powder. Soluble in tetrahydrofuran; sparingly soluble in ethanol; practically insoluble in water. ● (RB 1-Dec-2012)

Ademetionine Disulfate Tosylate: White powder. Freely soluble in water.

Adenine: White crystals or crystalline powder. Is odorless and tasteless. Sparingly soluble in boiling water; slightly soluble in alcohol; very slightly soluble in water; practically insoluble in ether and in chloroform.

Adenosine: White, odorless, crystalline powder. Slightly soluble in water; practically insoluble in alcohol. Melts at about 235°.

Adipic Acid: A white, crystalline powder. Freely soluble in alcohol and in methanol; soluble in boiling water and in acetone; slightly soluble in water. *NF category*: Buffering agent.

Agar: Odorless or has a slight odor, and produces a mucilaginous sensation on the tongue. Soluble in boiling water; insoluble in cold water. *NF category*: Suspending and/or viscosity-increasing agent.

Alamic Acid: *NF category*: Suspending and/or viscosity-increasing agent.

Alanine: White, odorless crystals or crystalline powder, having a slightly sweet taste. Freely soluble in water; slightly soluble in 80% alcohol; insoluble in ether.

Albendazole: White to faintly yellowish powder. Freely soluble in anhydrous formic acid; very slightly soluble in ether and in methylene chloride; practically insoluble in alcohol and in water.

Albumin Human: Practically odorless, moderately viscous, clear, brownish fluid.

rAlbumin Human: Clear, slightly viscous, and colorless to yellow amber in color. *NF category*: Vehicle (sterile).

Albuterol: White, crystalline powder. Soluble in alcohol; sparingly soluble in water. Melts at about 156°.

Albuterol Sulfate: White or practically white powder. Freely soluble in water; slightly soluble in alcohol, in chloroform, and in ether.

Alcohol: Clear, colorless, mobile, volatile liquid. Has a characteristic odor and produces a burning sensation on the tongue. Is readily volatilized even at low temperatures, and boils at about 78°. Is flammable. Miscible with water and with practically all organic solvents. *NF category*: Solvent.

Dehydrated Alcohol: Clear, colorless, mobile, volatile liquid. Has a characteristic odor and produces a burning sensation on the tongue. Is readily volatilized even at low temperatures, and boils at about 78°. Is flammable. Miscible with water and with practically all organic solvents.

Diluted Alcohol: Clear, colorless, mobile liquid, having a characteristic odor and producing a burning sensation on the tongue. *NF category*: Solvent.

Rubbing Alcohol: Transparent, colorless, or colored as desired, mobile, volatile liquid. Has an extremely bitter taste and, in the absence of added odorous constituents, a characteristic odor. Is flammable.

Alendronate Sodium: White, free-flowing powder. Soluble in water; very slightly soluble in dimethyl sulfoxide, in

methyl alcohol, and in propylene glycol; practically insoluble in acetone, in acetonitrile, in alcohol, in chloroform, and in isopropyl alcohol.

Alfadex: A white or almost white, amorphous or crystalline powder. Freely soluble in water and in propylene glycol; practically insoluble in ethanol and in methylene chloride.

Alfentanil Hydrochloride: White to almost white powder. Freely soluble in methanol, in alcohol, and in chloroform; soluble in water; sparingly soluble in acetone. Melting point range, crystals from acetone: 136° – 143° (anhydrous) and reported as crystals from aqueous hydrochloric acid: 116° – 126° (monohydrate).

Alfentanil Injection: Clear, colorless solution.

Alfuzosin Hydrochloride: White to almost white powder, slightly hygroscopic. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in methylene chloride.

Alginic Acid: White to yellowish white, fibrous powder. Is odorless, or practically odorless, and is tasteless. Soluble in alkaline solutions; insoluble in water and in organic solvents. *NF category*: Suspending and/or viscosity-increasing agent; tablet binder; tablet disintegrant.

Alkyl (C12-15) Benzoate: Clear, practically colorless, oily liquid. Soluble in acetone, in alcohol, in isopropyl alcohol, in ethyl acetate, in isopropyl myristate, in isopropyl palmitate, in lanolin, in mineral oil, in vegetable oils, and in volatile silicones; insoluble in water, in glycerin, and in propylene glycol. *NF category*: Vehicle (oleaginous); emollient.

Allantoin: White, crystalline powder. Slightly soluble in water; very slightly soluble in alcohol. Melts at about 225°, with decomposition.

Allopurinol: Fluffy white to off-white powder, having only a slight odor. Soluble in solutions of potassium and sodium hydroxides; very slightly soluble in water and in alcohol; practically insoluble in chloroform and in ether.

Allyl Isothiocyanate: Colorless to pale yellow, very refractive, liquid. Pungent irritating odor, acrid taste. [Caution: Lachrymator.] Miscible with alcohol, with carbon disulfide, and with ether. Slightly soluble in water.

Almond Oil: Clear, pale straw-colored or colorless, oily liquid, having a bland taste. Remains clear at –10°, and does not congeal until cooled to almost –20°. Slightly soluble in alcohol. Miscible with ether, with chloroform, with benzene, and with solvent hexane. *NF category*: Flavors and perfumes; vehicle (oleaginous).

Aloe: Has a characteristic, somewhat sour and disagreeable, odor.

Alprazolam: A white to off-white, crystalline powder. Melts at about 225°. Freely soluble in chloroform; soluble in alcohol; sparingly soluble in acetone; slightly soluble in ethyl acetate; insoluble in water.

Alprostadil: A white to off-white, crystalline powder. Melts at about 110°. Freely soluble in alcohol; soluble in water and in acetone; slightly soluble in ethyl acetate; very slightly soluble in chloroform and in ether.

Altretamine: White, crystalline powder. Soluble in chloroform; insoluble in water.

Ammonium Alum: Large, colorless crystals, crystalline fragments, or white powder. Is odorless, and has a sweetish, strongly astringent taste. Its solutions are acid to litmus. Very soluble in boiling water; freely soluble in water; freely soluble in glycerin; insoluble in alcohol.

Potassium Alum: Large, colorless crystals, crystalline fragments, or white powder. Is odorless, and has a sweetish, strongly astringent taste. Its solutions are acid to litmus. Very soluble in boiling water; freely soluble in water; freely soluble in glycerin; insoluble in alcohol.

Aluminum Acetate Topical Solution: Clear, colorless liquid having a faint odor of acetic acid, and a sweetish, astringent taste. Specific gravity is about 1.02.

Aluminum Chloride: White, or yellowish-white, deliquescent, crystalline powder. Is practically odorless, and has a sweet, very astringent taste. Its solutions are acid to litmus. Very soluble in water; freely soluble in alcohol; soluble in glycerin.

Aluminum Hydroxide Gel: White, viscous suspension, from which small amounts of clear liquid may separate on standing.

Dried Aluminum Hydroxide Gel: White, odorless, tasteless, amorphous powder. Soluble in dilute mineral acids and in solutions of fixed alkali hydroxides; insoluble in water and in alcohol.

Aluminum Monostearate: Fine, white to yellowish-white, bulky powder, having a faint, characteristic odor. Insoluble in water, in alcohol, and in ether. *NF category:* Suspending and/or viscosity-increasing agent.

Aluminum Oxide: Occurs as a white or almost white, amorphous powder. It is very slightly soluble in dilute mineral acids and in solutions of alkali hydroxides. It is practically insoluble in water.

Aluminum Phosphate Gel: White, viscous suspension from which small amounts of water separate on standing.

Aluminum Subacetate Topical Solution: Clear, colorless or faintly yellow liquid, having an odor of acetic acid and an acid reaction to litmus. Gradually becomes turbid on standing, through separation of a more basic salt.

Aluminum Sulfate: White, crystalline powder, shining plates, or crystalline fragments. Is stable in air. Is odorless, and has a sweet taste, becoming mildly astringent. Freely soluble in water; insoluble in alcohol.

Amantadine Hydrochloride: White or practically white, crystalline powder, having a bitter taste. Freely soluble in water; soluble in alcohol and in chloroform.

Amifostine: White, crystalline powder. Freely soluble in water.

Amikacin: White, crystalline powder. Sparingly soluble in water.

Amikacin Sulfate: White, crystalline powder. Freely soluble in water.

Amiloride Hydrochloride: Yellow to greenish-yellow, odorless or practically odorless powder. Freely soluble in dimethyl sulfoxide; sparingly soluble in methanol; slightly soluble in water; insoluble in ether, in ethyl acetate, in acetone, and in chloroform.

Amino Methacrylate Copolymer: Colorless to yellowish granules. Soluble in acetone, in isopropyl alcohol, and in diluted acids; practically insoluble in water. The solutions are clear to slightly cloudy. *NF category:* Coating agent; polymer membrane; tablet binder.

Aminobenzoate Potassium: White, crystalline powder. The pH of a 1 in 100 solution in water is about 7. Very soluble in water; soluble in alcohol; practically insoluble in ether.

Aminobenzoic Acid: White or slightly yellow, odorless crystals or crystalline powder. Discolors on exposure to air or light. Freely soluble in alcohol and in solutions of alkali hydroxides and carbonates; sparingly soluble in ether; slightly soluble in water and in chloroform.

Aminobenzoic Acid Topical Solution: Straw-colored solution having the odor of alcohol.

Aminocaproic Acid: Fine, white, crystalline powder. Is odorless, or practically odorless. Its solutions are neutral to litmus. Melts at about 205°. Freely soluble in water, in acids, and in alkalies; slightly soluble in methanol and in alcohol; practically insoluble in chloroform and in ether.

Aminogluthethimide: Fine, white, or creamy white, crystalline powder. Soluble in most organic solvents; very slightly soluble in water. Forms water-soluble salts with strong acids.

Aminohippuric Acid: White, crystalline powder. Discolors on exposure to light. Melts at about 195°, with decomposition. Freely soluble in alkaline solutions, with some decomposition, and in diluted hydrochloric acid; sparingly soluble in water and in alcohol; very slightly soluble in benzene, in carbon tetrachloride, in chloroform, and in ether.

Aminopentamide Sulfate: White, crystalline powder. Freely soluble in water and in alcohol; very slightly soluble in chloroform; practically insoluble in ether.

Aminophylline: White or slightly yellowish granules or powder, having a slight ammoniacal odor and a bitter taste. Upon exposure to air, it gradually loses ethylenediamine and absorbs carbon dioxide with the liberation of free theophylline. Its solutions are alkaline to litmus. One g dissolves in 25 mL of water to give a clear solution; 1 g dissolved in 5 mL of water crystallizes upon standing, but redissolves when a small amount of ethylenediamine is added. Insoluble in alcohol and in ether.

Aminophylline Tablets: May have a faint ammoniacal odor.

Aminosalicylate Sodium: White to cream-colored, crystalline powder. Is practically odorless, and has a sweet, saline taste. Its solutions decompose slowly and darken in color. Freely soluble in water; sparingly soluble in alcohol; very slightly soluble in ether and in chloroform.

Aminosalicylic Acid: White or practically white, bulky powder, that darkens on exposure to light and air. Is odorless, or has a slight acetous odor. Soluble in alcohol; slightly soluble in water and in ether; practically insoluble in benzene.

Amiodarone Hydrochloride: White or almost white, fine, crystalline powder. Freely soluble in methylene chloride; soluble in methanol; sparingly soluble in alcohol; very slightly soluble in water.

Amitriptyline Hydrochloride: White or practically white, odorless or practically odorless, crystalline powder or small crystals. Freely soluble in water, in alcohol, in chloroform, and in methanol; insoluble in ether.

Amlodipine Besylate: A white or almost white powder. Freely soluble in methanol; sparingly soluble in alcohol; slightly soluble in 2-propanol and in water.

Strong Ammonia Solution: Clear, colorless liquid, having an exceedingly pungent, characteristic odor. Specific gravity is about 0.90. *NF category:* Alkalizing agent.

Aromatic Ammonia Spirit: Practically colorless liquid when recently prepared, but gradually acquiring a yellow color on standing. Has the taste of ammonia, has an aromatic and pungent odor, and is affected by light. Specific gravity is about 0.90.

Ammonio Methacrylate Copolymer: Colorless, clear to white-opaque granules or a white powder, both with a faint amine-like odor. Soluble to freely soluble in methanol, in alcohol, and in isopropyl alcohol, each of which contains small amounts of water; soluble to freely soluble in acetone, in ethyl acetate, and in methylene chloride. The solutions are clear to slightly cloudy. Insoluble in petroleum ether and in water. *NF category:* Coating agent; tablet binder; polymer membrane.

Ammonio Methacrylate Copolymer Dispersion: Milky-white liquids of low viscosity with a faint characteristic odor. Miscible with water in any proportion, the milky-white appearance being retained. A clear or slightly cloudy solution is obtained on mixing one part with five parts of acetone, alcohol, or isopropyl alcohol. When mixed with methanol in a ratio of 1:5, Ammonio Methacrylate Copolymer Dispersion Type A dissolves completely, and Ammonio Methacrylate Copolymer Dispersion Type B dissolves only partially. *NF category:* Coating agent; polymer membrane; tablet binder.

Ammonium Carbonate: White powder, or hard, white or translucent masses, having a strong odor of ammonia, without empyreuma, and a sharp, ammoniacal taste. Its solutions are alkaline to litmus. On exposure to air, it loses

ammonia and carbon dioxide, becoming opaque, and is finally converted into friable porous lumps or a white powder of ammonium bicarbonate. Freely soluble in water, but is decomposed by hot water. *NF category:* Alkalizing agent; buffering agent.

Ammonium Chloride: Colorless crystals or white, fine or coarse, crystalline powder. Has a cool, saline taste, and is somewhat hygroscopic. Freely soluble in water and in glycerin, and even more so in boiling water; sparingly soluble in alcohol.

Ammonium Molybdate: Colorless or slightly greenish or yellowish crystals. Soluble in water; practically insoluble in alcohol.

Ammonium Phosphate: Colorless or white granules or powder, having a saline taste. Freely soluble in water; practically insoluble in acetone and in alcohol. *NF category:* Buffering agent.

Ammonium Sulfate: Colorless or white crystals or granules that decompose at temperatures above 280°. One g is soluble in about 1.5 mL of water. It is insoluble in alcohol. The pH of a 0.1 M solution is between 4.5 and 6.0.

Amobarbital Sodium: White, friable, granular powder. Is odorless, has a bitter taste, and is hygroscopic. Its solutions decompose on standing, heat accelerating the decomposition. Very soluble in water; soluble in alcohol; practically insoluble in ether and in chloroform.

Amodiaquine: Very pale yellow to light tan-yellow, odorless powder. Sparingly soluble in 1.0 N hydrochloric acid; slightly soluble in alcohol; practically insoluble in water.

Amodiaquine Hydrochloride: Yellow, crystalline powder. Is odorless and has a bitter taste. Soluble in water; sparingly soluble in alcohol; very slightly soluble in benzene, in chloroform, and in ether.

Amoxapine: White to yellowish crystalline powder. Freely soluble in chloroform; soluble in tetrahydrofuran; sparingly soluble in methanol and in toluene; slightly soluble in acetone; practically insoluble in water.

Amoxicillin: White, practically odorless, crystalline powder. Slightly soluble in water and in methanol; insoluble in benzene, in carbon tetrachloride, and in chloroform.

Amphetamine Sulfate: White, odorless, crystalline powder, having a slightly bitter taste. Its solutions are acid to litmus, having a pH of 5 to 6. Freely soluble in water; slightly soluble in alcohol; practically insoluble in ether.

Amphotericin B: Yellow to orange powder; odorless or practically so. Soluble in dimethylformamide, in dimethyl sulfoxide, and in propylene glycol; slightly soluble in methanol; insoluble in water, in anhydrous alcohol, in ether, in benzene, and in toluene.

Amphotericin B for Injection: It yields a colloidal dispersion in water.

Ampicillin: White, practically odorless, crystalline powder. Slightly soluble in water and in methanol; insoluble in benzene, in carbon tetrachloride, and in chloroform.

Ampicillin Sodium: White to off-white, odorless or practically odorless, crystalline powder. Is hygroscopic. Very soluble in water and in isotonic sodium chloride and dextrose solutions.

Amprolium ($C_{14}H_{19}ClN_4 \cdot HCl$): White to light yellow powder. Freely soluble in water, in methanol, in alcohol, and in dimethylformamide; sparingly soluble in dehydrated alcohol; practically insoluble in isopropyl alcohol, in butyl alcohol, and in acetone.

Amyl Nitrite: Clear, yellowish liquid, having a peculiar, ethereal, fruity odor. Is volatile even at low temperatures, and is flammable. Boils at about 96°. Practically insoluble in water. Miscible with alcohol and with ether.

Amylene Hydrate: Clear, colorless liquid, having a camphoraceous odor. Its solutions are neutral to litmus. Freely

soluble in water. Miscible with alcohol, with chloroform, with ether, and with glycerin. *NF category:* Solvent.

Anagrelide Hydrochloride: Off-white to pale pinkish powder. Sparingly soluble in dimethylsulfoxide and dimethylformamide; very slightly soluble in water.

Anastrozole: White to off-white crystalline powder. Very soluble in acetonitrile; freely soluble in methanol, in acetone, in alcohol, and in tetrahydrofuran.

Anethole: Colorless or faintly yellow liquid at or above 23°. Has a sweet taste and the aromatic odor of anise. Is affected by light. Freely soluble in alcohol; very slightly soluble in water. Readily miscible with ether and with chloroform. *NF category:* Flavors and perfumes.

Anileridine: White to yellowish-white, odorless to practically odorless, crystalline powder. Is oxidized on exposure to air and light, becoming darker in color. It exhibits polymorphism, and of two crystalline forms observed, one melts at about 80° and the other at about 89°. Freely soluble in alcohol and in chloroform; soluble in ether, although it may show turbidity; very slightly soluble in water.

Anileridine Hydrochloride: White or nearly white, odorless, crystalline powder. Is stable in air. Melts at about 270°, with decomposition. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in ether, and in chloroform.

Antazoline Phosphate: White to off-white, crystalline powder, having a bitter taste. Soluble in water; sparingly soluble in methanol; practically insoluble in benzene and in ether.

Anthralin: Yellowish-brown, crystalline powder. Is odorless and tasteless. Soluble in chloroform, in acetone, in benzene, and in solutions of alkali hydroxides; slightly soluble in alcohol, in ether, and in glacial acetic acid; insoluble in water.

Anticoagulant Citrate Dextrose Solution: Clear, colorless, odorless liquid. Is dextrorotatory.

Anticoagulant Citrate Phosphate Dextrose Solution: Clear, colorless to slightly yellow, odorless liquid. Is dextrorotatory.

Anticoagulant Sodium Citrate Solution: Clear and colorless liquid.

Antihemophilic Factor: White or yellowish powder. On constitution is opalescent with a slight blue tinge or is a yellowish liquid.

Cryoprecipitated Antihemophilic Factor: Yellowish, frozen solid. On thawing becomes a very viscous, yellow, gummy liquid.

Antimony Potassium Tartrate: Colorless, odorless, transparent crystals, or white powder. The crystals effloresce upon exposure to air and do not readily rehydrate even on exposure to high humidity. Its solutions are acid to litmus. Freely soluble in boiling water; soluble in water and in glycerin; insoluble in alcohol.

Antimony Sodium Tartrate: Colorless, odorless, transparent crystals, or white powder. The crystals effloresce upon exposure to air. Freely soluble in water; insoluble in alcohol.

Antipyrine: Colorless crystals, or white, crystalline powder. Is odorless and has a slightly bitter taste. Its solutions are neutral to litmus. Very soluble in water; freely soluble in alcohol and in chloroform; sparingly soluble in ether.

Antivenin (Crotalidae) Polyvalent: Solid exhibiting the characteristic structure of a freeze-dried solid; light cream in color.

Antivenin (Micrurus Fulvius): Solid exhibiting the characteristic structure of a freeze-dried solid; light cream in color.

Apomorphine Hydrochloride: Minute, white or grayish-white, glistening crystals or white powder. Is odorless. It gradually acquires a green color on exposure to light and air. Its solutions are neutral to litmus. Soluble in water at

80°; sparingly soluble in water and in alcohol; very slightly soluble in chloroform and in ether.

Apraclonidine Hydrochloride: White to off-white, odorless to practically odorless powder. Soluble in methanol; sparingly soluble in water and in alcohol; insoluble in chloroform, in ethyl acetate, and in hexanes.

Arginine: White, practically odorless crystals. Freely soluble in water; sparingly soluble in alcohol; insoluble in ether.

Arginine Hydrochloride: White crystals or crystalline powder, practically odorless. Freely soluble in water.

Aromatic Elixir: *NF category:* Vehicle (flavored and/or sweetened).

Arsanilic Acid: White to off-white, crystalline powder. Melts at about 232°. Soluble in hot water, in amyl alcohol, and in solutions of alkali carbonates; sparingly soluble in concentrated mineral acids; slightly soluble in cold water, in alcohol, and in acetic acid; insoluble in acetone, in benzene, in chloroform, in ether, and in dilute mineral acids.

Articaine Hydrochloride: White or almost white, crystalline powder. Freely soluble in water and in alcohol.

Ascorbic Acid: White or slightly yellow crystals or powder. On exposure to light it gradually darkens. In the dry state, is reasonably stable in air, but in solution rapidly oxidizes. Melts at about 190°. Freely soluble in water; sparingly soluble in alcohol; insoluble in chloroform, in ether, and in benzene. *NF category:* Antioxidant.

Ascorbyl Palmitate: White to yellowish white powder, having a characteristic odor. Soluble in alcohol; very slightly soluble in water and in vegetable oils. *NF category:* Antioxidant.

Asparagine: White crystals or a crystalline powder. Soluble in water; practically insoluble in alcohol and in ether. Its solutions are acid to litmus. It melts at about 234°.

Aspartame: White, odorless, crystalline powder, having a sweet taste. Sparingly soluble in water; slightly soluble in alcohol. Melts at about 246°. The pH of an 8 in 1000 solution is about 5. *NF category:* Sweetening agent.

Aspartame Acesulfame: White, odorless, crystalline powder. Slightly soluble in water and in ethanol. *NF category:* Sweetening agent.

Aspartic Acid: White or almost white, crystalline powder, or colorless crystals. Soluble in dilute solutions of alkali hydroxides and in dilute mineral acids; slightly soluble in water; practically insoluble in alcohol and in ether.

Aspirin: White crystals, commonly tabular or needle-like, or white, crystalline powder. Is odorless or has a faint odor. Is stable in dry air; in moist air it gradually hydrolyzes to salicylic and acetic acids. Freely soluble in alcohol; soluble in chloroform and in ether; sparingly soluble in absolute ether; slightly soluble in water.

Atenolol: White or practically white, odorless powder. Melting point 146° – 148° (crystals from ethyl acetate). Freely soluble in methanol; sparingly soluble in alcohol; slightly soluble in water and in isopropanol.

Atorvastatin Calcium: White to off-white crystalline powder. Freely soluble in methanol; slightly soluble in alcohol; very slightly soluble in distilled water, in pH 7.4 phosphate buffer, and in acetonitrile; insoluble in aqueous solutions of pH 4 and below.

Atovaquone: Yellow powder. Freely soluble in *N*-methyl-2-pyrrolidone and in tetrahydrofuran; soluble in chloroform; sparingly soluble in acetone, in di-*n*-butyl adipate, in dimethyl sulfoxide, and in polyethylene glycol 400; slightly soluble in alcohol, in 1,3-butanediol, in ethyl acetate, in glycerin, in octanol, and in polyethylene glycol 200; very slightly soluble in 0.1 N sodium hydroxide; insoluble in water.

Atracurium Besylate: White to yellowish-white powder, slightly hygroscopic. Very soluble in acetonitrile, in alcohol, and in methylene chloride; soluble in water.

Atropine: White crystals, usually needle-like, or white, crystalline powder. Its saturated solution is alkaline to phenolphthalein TS. Is optically inactive, but usually contains some levorotatory hyoscyamine. Freely soluble in alcohol and in chloroform; soluble in glycerin and in ether; slightly soluble in water; sparingly soluble in water at 80°.

Atropine Sulfate: Colorless crystals, or white, crystalline powder. Odorless; effloresces in dry air; is slowly affected by light. Very soluble in water; freely soluble in alcohol and even more so in boiling alcohol; freely soluble in glycerin.

Activated Attapulgate: Cream-colored, micronized, nonswelling powder, free from gritty particles. The high heat treatment used in its preparation causes it to yield only moderately viscous aqueous suspensions, its dispersion consisting mainly of particle groups. Insoluble in water. *NF category:* Suspending and/or viscosity-increasing agent.

Colloidal Activated Attapulgate: Cream-colored, micronized, nonswelling powder, free from gritty particles. Yields viscous aqueous suspensions, as a result of dispersion into its constituent ultimate particles. Insoluble in water. *NF category:* Suspending and/or viscosity-increasing agent.

Aurothioglucose: Yellow, odorless or practically odorless powder. Is stable in air. An aqueous solution is unstable on long standing. The pH of its 1 in 100 solution is about 6.3. Freely soluble in water; practically insoluble in acetone, in alcohol, in chloroform, and in ether.

Azatadine Maleate: White to light cream-colored, odorless powder. Melts at about 153°. Freely soluble in water, in alcohol, in chloroform, and in methanol; practically insoluble in benzene and in ether.

Azathioprine: Pale yellow, odorless powder. Soluble in dilute solutions of alkali hydroxides; sparingly soluble in dilute mineral acids; very slightly soluble in alcohol and in chloroform; insoluble in water.

Azathioprine Sodium for Injection: Bright yellow, hygroscopic, amorphous mass or cake.

Azithromycin: White or almost white powder. Freely soluble in anhydrous ethanol and in methylene chloride; practically insoluble in water.

Aztreonam: White, odorless, crystalline powder. Soluble in dimethylformamide and in dimethyl sulfoxide; slightly soluble in methanol; very slightly soluble in dehydrated alcohol; practically insoluble in ethyl acetate, in chloroform, and in toluene.

Bacampicillin Hydrochloride: White or practically white powder. Is hygroscopic. Freely soluble in alcohol and in chloroform; soluble in methylene chloride and in water; very slightly soluble in ether.

Bacitracin: White to pale buff powder, odorless or having a slight odor. Is hygroscopic. Its solutions deteriorate rapidly at room temperature. Is precipitated from its solutions and is inactivated by salts of many of the heavy metals. Freely soluble in water; soluble in alcohol, in methanol, and in glacial acetic acid, the solution in the organic solvents usually showing some insoluble residue; insoluble in acetone, in chloroform, and in ether.

Bacitracin Zinc: White to pale tan powder, odorless or having a slight odor. Is hygroscopic. Sparingly soluble in water.

Baclofen: White to off-white, crystalline powder. Is odorless or practically so. Slightly soluble in water; very slightly soluble in methanol; insoluble in chloroform.

Balsalazide Disodium: Orange to yellow powder. Freely soluble in water and in isotonic saline; sparingly soluble in methanol and in alcohol; practically insoluble in all other organic solvents.

Adhesive Bandage: The compress of Adhesive Bandage is substantially free from loose threads or ravelings. The adhesive strip may be perforated, and the back may be coated with a water-repellent film.

Gauze Bandage: One continuous piece, tightly rolled, in various widths and lengths and substantially free from loose threads and ravelings.

Barium Hydroxide Lime: White or grayish-white granules. May have a color if an indicator has been added. *NF category:* Sorbent, carbon dioxide.

Barium Sulfate: Fine, white, odorless, tasteless, bulky powder, free from grittiness. Practically insoluble in water, in organic solvents, and in solutions of acids and of alkalis.

Barium Sulfate for Suspension: White or colored, bulky or granular powder.

BCG Vaccine: White to creamy white, dried mass, having the characteristic texture of material dried in the frozen state.

Beclomethasone Dipropionate: White to cream white, odorless powder. Very soluble in chloroform; freely soluble in acetone and in alcohol; very slightly soluble in water.

Behenoyl Polyoxylglycerides: Waxy solid or fine powder. Soluble in methylene chloride; insoluble in alcohol; dispersible in water. *NF category:* Tablet and/or capsule lubricant.

Belladonna Leaf: When moistened, its odor is slight, somewhat tobacco-like. Its taste is somewhat bitter and acrid.

Benazepril Hydrochloride: White to off-white, crystalline powder. Soluble in water, in methanol, and in alcohol.

Bendroflumethiazide: White to cream-colored, finely divided, crystalline powder. Is odorless, or has a slight odor. Melts at about 220°. Freely soluble in alcohol and in acetone; practically insoluble in water.

Benoxinate Hydrochloride: White, or slightly off-white, crystals or crystalline powder. Is odorless, or has a slight characteristic odor, has a salty taste, and exhibits local anesthetic properties when placed upon the tongue. Its solutions are neutral to litmus, and it melts at about 158°. Very soluble in water; freely soluble in chloroform and in alcohol; insoluble in ether.

Bentonite: Very fine, odorless, pale buff or cream-colored to grayish powder, free from grit. Has a slightly earthy taste. Is hygroscopic. Insoluble in water, but swells to approximately twelve times its volume when added to water; insoluble in, and does not swell in, organic solvents. *NF category:* Suspending and/or viscosity-increasing agent.

Purified Bentonite: Odorless, tasteless, fine (micronized) powder or small flakes that are creamy when viewed on their flat surfaces and tan to brown when viewed on their edges. Insoluble in water and in alcohol. Swells when added to water or glycerin. *NF category:* Suspending and/or viscosity-increasing agent.

Bentonite Magma: *NF category:* Suspending and/or viscosity-increasing agent.

Change to read:

Benzaldehyde: Colorless, strongly refractive liquid.

▲ *NF31* Is affected by light. Slightly soluble in water. Miscible with alcohol, with ether, and with fixed and volatile oils. ▲ The specific gravity is 1.041–1.046 at 25° (see *Specific Gravity* (841)), and the refractive index is 1.544–1.546 at 20° (see *Refractive Index* (831)). ▲ *NF31* *NF category:* Flavors and perfumes.

Benzaldehyde Elixir, Compound: *NF category:* Flavored and/or sweetened vehicle.

Benzalkonium Chloride: White or yellowish-white, thick gel or gelatinous pieces. Usually has a mild, aromatic odor. Its aqueous solution has a bitter taste, foams strongly when shaken, and usually is slightly alkaline. Very soluble in water and in alcohol. Anhydrous form freely soluble in benzene, and slightly soluble in ether. *NF category:* Antimicrobial preservative; wetting and/or solubilizing agent.

Benzalkonium Chloride Solution: Clear liquid; colorless or slightly yellow unless a color has been added. Has an aromatic odor and a bitter taste. *NF category:* Antimicrobial preservative.

Benzethonium Chloride: White crystals, having a mild odor. Its solution (1 in 100) is slightly alkaline to litmus. Soluble in water, in alcohol, and in chloroform; slightly soluble in ether. *NF category:* Antimicrobial preservative; wetting and/or solubilizing agent.

Benzethonium Chloride Solution: Odorless, clear liquid, slightly alkaline to litmus.

Benzethonium Chloride Tincture: Clear liquid, having the characteristic odor of acetone and of alcohol.

Benzocaine: Small, white crystals or white, crystalline powder. Is odorless, is stable in air, and exhibits local anesthetic properties when placed upon the tongue. Freely soluble in alcohol, in chloroform, and in ether; sparingly soluble in almond oil and in olive oil; very slightly soluble in water. Dissolves in dilute acids.

Benzoic Acid: White crystals, scales, or needles. Has a slight odor, usually suggesting benzaldehyde or benzoin. Somewhat volatile at moderately warm temperatures. Freely volatile in steam. Freely soluble in alcohol, in chloroform, and in ether; slightly soluble in water. *NF category:* Antimicrobial preservative.

Benzoin: Sumatra Benzoin has an aromatic and balsamic odor. When heated it does not emit a pinaceous odor. When Sumatra Benzoin is digested with boiling water, the odor suggests cinnamates or storax. Its taste is aromatic and slightly acrid. Siam Benzoin has an agreeable, balsamic, vanilla-like odor. Its taste is aromatic and slightly acrid.

Benzonate: Clear, pale yellow, viscous liquid, having a faint, characteristic odor. Has a bitter taste, and exhibits local anesthetic properties when placed upon the tongue. Miscible with water in all proportions. Freely soluble in chloroform, in alcohol, and in benzene.

Hydrous Benzoyl Peroxide: White, granular powder, having a characteristic odor. Soluble in acetone, in chloroform, and in ether; sparingly soluble in water and in alcohol.

Benzoyl Peroxide Gel: A soft, white gel, having a characteristic odor.

Benzoyl Peroxide Lotion: White, viscous, creamy lotion, having a characteristic odor.

Benzotropine Mesylate: White, slightly hygroscopic, crystalline powder. Very soluble in water; freely soluble in alcohol; very slightly soluble in ether.

Benzyl Alcohol: Clear, colorless, oily liquid. Boils at about 206°, without decomposition. Is neutral to litmus. Freely soluble in 50% alcohol; sparingly soluble in water. Miscible with alcohol, with ether, and with chloroform. The specific gravity is between 1.042 and 1.047. *NF category:* Antimicrobial preservative.

Benzyl Benzoate: Clear, colorless, oily liquid having a slight aromatic odor and producing a sharp, burning sensation on the tongue. Practically insoluble in water and in glycerin. Miscible with alcohol, with ether, and with chloroform. *NF category:* Solvent.

Beta Carotene: Red or reddish-brown to violet-brown crystals or crystalline powder. Soluble in carbon disulfide, in benzene, and in chloroform; sparingly soluble in ether, in solvent hexane, and in vegetable oils; practically insoluble in methanol and in alcohol; insoluble in water and in acids and in alkalis.

Betadex: White, practically odorless, fine crystalline powder having a slightly sweet taste. Sparingly soluble in water. *NF category:* Sequestering agent.

Betadex Sulfobutyl Ether Sodium: White to off-white, amorphous powder. Freely soluble in water; sparingly soluble in methanol; practically insoluble in ethanol, in *n*-hexane, in 1-butanol, in acetonitrile, in 2-propanol, and in ethyl

acetate. *NF category:* Complexing agent; sequestering agent; wetting and/or solubilizing agent.

Betahistine Hydrochloride: White to almost yellow, crystalline powder. Very hygroscopic. Melts between 151° and 154°. Very soluble in water; freely soluble in alcohol; practically insoluble in isopropyl alcohol.

Betaine Hydrochloride: White, crystalline powder. Soluble in water and in alcohol; practically insoluble in chloroform and in ether.

Betamethasone: White to practically white, odorless, crystalline powder. Melts at about 240°, with some decomposition. Sparingly soluble in acetone, in alcohol, in dioxane, and in methanol; very slightly soluble in chloroform and in ether; insoluble in water.

Betamethasone Acetate: White to creamy white, odorless powder. Sinters and resolidifies at about 165°, and remelts at about 200° or 220°, with decomposition (see *Melting Range or Temperature* (741)). Freely soluble in acetone; soluble in alcohol and in chloroform; practically insoluble in water.

Betamethasone Benzoate: White to practically white, practically odorless powder. Melts at about 220°, with decomposition. Soluble in alcohol, in methanol, and in chloroform; insoluble in water.

Betamethasone Dipropionate: White to cream-white, odorless powder. Freely soluble in acetone and in chloroform; sparingly soluble in alcohol; insoluble in water.

Betamethasone Sodium Phosphate: White to practically white, odorless powder. Is hygroscopic. Freely soluble in water and in methanol; practically insoluble in acetone and in chloroform.

Betamethasone Valerate: White to practically white, odorless powder. Melts at about 190°, with decomposition. Freely soluble in acetone and in chloroform; soluble in alcohol; slightly soluble in benzene and in ether; practically insoluble in water.

Betaxolol Hydrochloride: White, crystalline powder. Freely soluble in water, in alcohol, in chloroform, and in methanol.

Bethanechol Chloride: Colorless or white crystals or white, crystalline powder, usually having a slight, amine-like odor. Is hygroscopic. Exhibits polymorphism, and of two crystalline forms observed, one melts at about 211° and the other melts at about 219°. Freely soluble in water and in alcohol; insoluble in chloroform and in ether.

Bicalutamide: Fine, white to off-white powder. Freely soluble in tetrahydrofuran and in acetone; soluble in acetonitrile; sparingly soluble in methanol; slightly soluble in alcohol.

Biotin: Practically white, crystalline powder. Very slightly soluble in water and in alcohol; insoluble in other common organic solvents.

Biperiden: White, practically odorless, crystalline powder. Freely soluble in chloroform; sparingly soluble in alcohol; practically insoluble in water.

Biperiden Hydrochloride: White, practically odorless, crystalline powder. Melts at about 275°, with decomposition. Is optically inactive. Sparingly soluble in methanol; slightly soluble in water, in ether, in alcohol, and in chloroform.

Bisacodyl: White to off-white, crystalline powder, in which the number of particles having a longest diameter smaller than 50 µm predominate. Soluble in chloroform and in benzene; sparingly soluble in alcohol and in methanol; slightly soluble in ether; practically insoluble in water.

Milk of Bismuth: Thick, white, opaque suspension that separates on standing. Is odorless and practically tasteless. Miscible with water and with alcohol.

Bismuth Citrate: White, amorphous or crystalline powder. Stable in air. Melts at about 300°, with decomposition.

Soluble in ammonia TS and in solutions of alkali citrates; insoluble in water and in alcohol.

Bismuth Subcarbonate: White or almost white powder. Practically insoluble in water, in alcohol, and in ether. Dissolves in dilute acids with effervescence.

Bismuth Subgallate: Amorphous, bright yellow powder. Is odorless and tasteless. Is stable in air, but is affected by light. Dissolves readily with decomposition in warm, moderately dilute hydrochloric, nitric, or sulfuric acid; readily dissolved by solutions of alkali hydroxides, forming a clear, yellow liquid that rapidly assumes a deep red color. Practically insoluble in water, in alcohol, in chloroform, and in ether; insoluble in very dilute mineral acids.

Bismuth Subnitrate: White, slightly hygroscopic powder. Practically insoluble in water and in alcohol; readily dissolved by hydrochloric acid or by nitric acid.

Bismuth Subsalcylate: Fine to off-white, microcrystalline, odorless, tasteless powder. Practically insoluble in water, in alcohol, and in ether. Reacts with alkalies and mineral acids.

Bisoprolol Fumarate: White, crystalline powder. Very soluble in water and in methanol; freely soluble in chloroform, in glacial acetic acid, and in alcohol; slightly soluble in acetone and in ethyl acetate.

Bleomycin Sulfate: Cream-colored, amorphous powder. Very soluble in water.

Anti-A Blood Grouping Serum: Liquid Serum is a clear or slightly opalescent fluid unless artificially colored blue. Dried Serum is light yellow to deep cream color, unless artificially colored as indicated for liquid Serum. The liquid Serum may develop slight turbidity on storage. The dried Serum may show slight turbidity upon reconstitution for use.

Anti-B Blood Grouping Serum: Liquid Serum is a clear or slightly opalescent fluid unless artificially colored yellow. Dried Serum is light yellow to deep cream color, unless artificially colored as indicated for liquid Serum. The liquid Serum may develop a slight turbidity on storage. The dried Serum may show slight turbidity upon reconstitution for use.

Blood Grouping Serums Anti-D, Anti-C, Anti-E, Anti-c, Anti-e: The liquid Serums are clear, slightly yellowish fluids, that may develop slight turbidity on storage. The dried Serums are light yellow to deep cream color.

Blood Group Specific Substances A, B, and AB: Clear solution that may have a slight odor because of the preservative.

Red Blood Cells: Dark red in color when packed. May show a slight creamy layer on the surface and a small supernatant layer of yellow or opalescent plasma. Also supplied in deep-frozen form with added cryoprotective substance to extend storage time.

Whole Blood: Deep red, opaque liquid from which the corpuscles readily settle upon standing for 24 to 48 hours, leaving a clear, yellowish or pinkish supernatant layer of plasma.

Boric Acid: Colorless, odorless scales of a somewhat pearly luster, or crystals, or white powder that is slightly unctuous to the touch. Is stable in air. Freely soluble in glycerin, in boiling water, and in boiling alcohol; soluble in water and in alcohol. *NF category:* Buffering agent.

Botulism Antitoxin: Transparent or slightly opalescent liquid, practically colorless, and practically odorless or having an odor because of the antimicrobial agent.

Bretylum Tosylate: White, crystalline powder. Is hygroscopic. Freely soluble in water, in methanol, and in alcohol; practically insoluble in ether, in ethyl acetate, and in hexane.

Brinzolamide: White or almost white powder. Slightly soluble in alcohol and in methanol; insoluble in water.

Bromocriptine Mesylate: White or slightly colored, fine crystalline powder, odorless or having a weak, characteristic odor.

Bromodiphenhydramine Hydrochloride: White to pale buff, crystalline powder, having no more than a faint odor. Freely soluble in water and in alcohol; soluble in isopropyl alcohol; insoluble in ether and in solvent hexane.

Brompheniramine Maleate: White, odorless, crystalline powder. Freely soluble in water; soluble in alcohol and in chloroform; slightly soluble in ether and in benzene.

Budesonide: White to off-white, odorless, crystalline powder. Freely soluble in chloroform; sparingly soluble in alcohol; practically insoluble in water and in heptane.

Bumetanide: Practically white powder. Soluble in alkaline solutions; slightly soluble in water.

Bupivacaine Hydrochloride: White, odorless, crystalline powder. Melts at about 248°, with decomposition. Freely soluble in water and in alcohol; slightly soluble in chloroform and in acetone.

Bupivacaine Hydrochloride Injection: Clear, colorless solution.

Bupivacaine Hydrochloride and Epinephrine Injection: Clear, colorless solution.

Bupropion Hydrochloride: White powder. Soluble in water, in 0.1 N hydrochloric acid, and in alcohol.

Busulfan: White, crystalline powder. Sparingly soluble in acetone; slightly soluble in alcohol; very slightly soluble in water.

Buspiron Hydrochloride: White crystalline powder. Very soluble in water; freely soluble in methanol and in methylene chloride; sparingly soluble in ethanol and in acetonitrile; very slightly soluble in ethyl acetate; practically insoluble in hexanes.

Butabarbital: White, odorless, crystalline powder. Soluble in alcohol, in chloroform, in ether, and in solutions of alkali hydroxides and carbonates; very slightly soluble in water.

Butabarbital Sodium: White powder, having a bitter taste. Freely soluble in water and in alcohol; practically insoluble in absolute ether.

Butalbital: White, crystalline, odorless powder, having a slightly bitter taste. Is stable in air. Its saturated solution is acid to litmus. Freely soluble in alcohol, in ether, and in chloroform; soluble in boiling water, and in solutions of fixed alkalis and alkali carbonates; slightly soluble in cold water.

Butamben: White, crystalline powder. Is odorless and tasteless. Soluble in dilute acids, in alcohol, in chloroform, in ether, and in fixed oils; very slightly soluble in water. Is slowly hydrolyzed when boiled with water.

Butane: Colorless, flammable gas (boiling temperature is about -0.5°). One volume of water dissolves 0.15 volume, and 1 volume of alcohol dissolves 18 volumes at 17° and 770 mm; 1 volume of ether or chloroform at 17° dissolves 25 or 30 volumes, respectively. Vapor pressure at 21° is about 1620 mm of mercury (17 psig). *NF category:* Aerosol propellant.

Butoconazole Nitrate: White to off-white, crystalline powder. Melts at about 160°. Sparingly soluble in methanol; slightly soluble in acetonitrile, in acetone, in dichloromethane, and in tetrahydrofuran; very slightly soluble in ethyl acetate; practically insoluble in water.

Butorphanol Tartrate: White powder. Its solutions are slightly acidic. Melts between 217° and 219°, with decomposition. Soluble in dilute acids; sparingly soluble in water; slightly soluble in methanol; insoluble in alcohol, in chloroform, in ethyl acetate, in ethyl ether, and in hexane.

Butyl Alcohol: Clear, colorless, mobile liquid, having a characteristic, penetrating vinous odor. Soluble in water. Miscible with alcohol, with ether, and with many other organic solvents. *NF category:* Solvent.

Butylated Hydroxyanisole: White or slightly yellow, waxy solid, having a faint, characteristic odor. Freely soluble in alcohol, in propylene glycol, in chloroform, and in ether; insoluble in water. *NF category:* Antioxidant.

Butylated Hydroxytoluene: White, crystalline solid, having a faint, characteristic odor. Freely soluble in alcohol, in chloroform, and in ether; insoluble in water and in propylene glycol. *NF category:* Antioxidant.

Butylparaben: Small, colorless crystals or white powder. Freely soluble in acetone, in alcohol, in ether, and in propylene glycol; very slightly soluble in water and in glycerin. *NF category:* Antimicrobial preservative.

Cabergoline: White or almost white, crystalline powder. Freely soluble in alcohol (96%); slightly soluble in 0.1 M hydrochloric acid; very slightly soluble in hexane; practically insoluble in water.

Caffeine: White powder or white, glistening needles, usually matted together. Is odorless and has a bitter taste. Its solutions are neutral to litmus. The hydrate is efflorescent in air. Freely soluble in chloroform; sparingly soluble in water and in alcohol; slightly soluble in ether.

Calamine: Pink, odorless, practically tasteless, fine powder. Soluble in mineral acids; insoluble in water.

Calcitriol: White or almost white crystals. Freely soluble in alcohol; soluble in ether and in fatty oils; practically insoluble in water. It is sensitive to air, heat, and light.

Calcium Acetate: White, odorless or almost odorless, hygroscopic, crystalline powder. When heated to above 160°, it decomposes to calcium carbonate and acetone. Freely soluble in water; slightly soluble in methanol; practically insoluble in acetone, in dehydrated alcohol, and in benzene.

Calcium Ascorbate: White to slightly yellow, practically odorless powder. Freely soluble in water (approximately 50 g per 100 mL); slightly soluble in alcohol; insoluble in ether.

Calcium Carbonate: Fine, white, odorless, tasteless, microcrystalline powder. Is stable in air. Practically insoluble in water. Its solubility in water is increased by the presence of any ammonium salt or of carbon dioxide. The presence of any alkali hydroxide reduces its solubility. Insoluble in alcohol. Dissolves with effervescence in 1 N acetic acid, in 3 N hydrochloric acid, and in 2 N nitric acid. *NF category:* Tablet and/or capsule diluent.

Calcium Chloride: White, hard, odorless fragments or granules. Is deliquescent. Very soluble in boiling water; freely soluble in water, in alcohol, and in boiling alcohol. *NF category:* Desiccant.

Calcium Citrate: White, odorless, crystalline powder. Freely soluble in diluted 3 N hydrochloric acid and in diluted 2 N nitric acid; slightly soluble in water; insoluble in alcohol.

Calcium Gluceptate: White to faintly yellow, amorphous powder. Is stable in air, but the hydrous forms may lose part of their water of hydration on standing. Freely soluble in water; insoluble in alcohol and in many other organic solvents.

Calcium Gluconate: White, crystalline, odorless, tasteless granules or powder. Is stable in air. Its solutions are neutral to litmus. Freely soluble in boiling water; sparingly (and slowly) soluble in water; insoluble in alcohol.

Calcium Hydroxide: White powder. Has an alkaline, slightly bitter taste. Soluble in glycerin and in syrup; slightly soluble in water; very slightly soluble in boiling water; insoluble in alcohol.

Calcium Hydroxide Solution: Clear, colorless liquid having an alkaline taste. Is alkaline to litmus.

Calcium Lactate: White, practically odorless granules or powder. The pentahydrate is somewhat efflorescent and at 120° becomes anhydrous. The pentahydrate is soluble in water; it is practically insoluble in alcohol.

Calcium Levulinate: White, crystalline or amorphous, powder, having a faint odor suggestive of burnt sugar. Has a bitter, salty taste. Freely soluble in water; slightly soluble in alcohol; insoluble in ether and in chloroform.

Calcium Pantothenate: Slightly hygroscopic, white powder. Is odorless and has a bitter taste. Freely soluble in water; soluble in glycerin; practically insoluble in alcohol, in chloroform, and in ether.

Racemic Calcium Pantothenate: White, slightly hygroscopic powder, having a faint, characteristic odor, and a bitter taste. Is stable in air. Its solutions are neutral or alkaline to litmus. Is optically inactive. Freely soluble in water; soluble in glycerin; practically insoluble in alcohol, in chloroform, and in ether.

Dibasic Calcium Phosphate: White, odorless, tasteless powder. Is stable in air. Soluble in 3 N hydrochloric acid and in 2 N nitric acid; practically insoluble in water; insoluble in alcohol. *NF category:* Tablet and/or capsule diluent.

Tribasic Calcium Phosphate: White, odorless, tasteless powder. Is stable in air. Freely soluble in 3 N hydrochloric acid and in 2 N nitric acid; practically insoluble in water; insoluble in alcohol. *NF category:* Tablet and/or capsule diluent.

Calcium Polycarbophil: White to creamy white powder. Insoluble in water, in dilute acids, in dilute alkalies, and in common organic solvents.

Calcium Propionate: Occurs as a white crystalline solid. One g dissolves in about 3 mL of water. *NF category:* Antimicrobial preservative.

Calcium Saccharate: White, odorless, tasteless, crystalline powder. Soluble in dilute mineral acids and in solutions of calcium gluconate; slightly soluble in boiling water; very slightly soluble in alcohol, and in cold water; practically insoluble in ether and in chloroform.

Calcium Silicate: White to off-white, free-flowing powder that remains so after absorbing relatively large amounts of water or other liquids. Insoluble in water. Forms a gel with mineral acids. *NF category:* Glidant and/or anticaking agent.

Calcium Stearate: Fine, white to yellowish-white, bulky powder having a slight, characteristic odor. Is unctuous, and is free from grittiness. Insoluble in water, in alcohol, and in ether. *NF category:* Tablet and/or capsule lubricant.

Calcium Sulfate: Fine, white to slightly yellow-white, odorless powder. Soluble in 3 N hydrochloric acid; slightly soluble in water. *NF category:* Desiccant; tablet and/or capsule diluent.

Calcium Undecylenate: Fine, white powder, having a characteristic odor and no grit. Slightly soluble in hot alcohol; practically insoluble in water, in ether, in chloroform, in acetone, and in cold alcohol.

Camphor: Colorless or white crystals, granules, or crystalline masses; or colorless to white, translucent, tough masses. Has a penetrating, characteristic odor and a pungent, aromatic taste. Specific gravity is about 0.99. Slowly volatilizes at ordinary temperatures. Slightly soluble in water; very soluble in alcohol, in chloroform, and in ether; freely soluble in carbon disulfide, in solvent hexane, and in fixed and volatile oils.

Candelilla Wax: A hard, yellowish-brown-opaque to translucent wax. Its specific gravity is about 0.983. Soluble in chloroform and in toluene; insoluble in water.

Candesartan Cilexetil: White to off-white powder. Sparingly soluble in methanol; practically insoluble in water.

Canola Oil: Clear, pale yellow, slightly viscous liquid. Practically insoluble in water and in alcohol. Miscible with light petroleum (bp: 40° to 60°). *NF category:* Solvent; vehicle (oleaginous).

Capecitabine: White to off-white crystalline powder. Freely soluble in methanol; soluble in acetonitrile and in alcohol; sparingly soluble in water.

Capreomycin Sulfate: White to practically white, amorphous powder. Freely soluble in water; practically insoluble in most organic solvents.

Add the following:

▲ **Caprylic Acid:** Clear, colorless or slightly yellowish, oily liquid. Very soluble in acetone and in alcohol; very slightly soluble in water. It dissolves in dilute solutions of alkali hydroxides. *NF category:* Emulsifying and/or solubilizing agent.▲ *NF31*

Caprylocaproyl Polyoxylglycerides: Pale yellow, oily liquids. Dispersible in hot water; freely soluble in methylene chloride. *NF category:* Ointment base; solvent.

Capsaicin: Off-white powder. Melts at about 65°. Soluble in alcohol, in benzene, in chloroform; slightly soluble in carbon disulfide; practically insoluble in cold water.

Capsicum Oleoresin: Dark red, oily liquid. Soluble in alcohol, in acetone, in ether, in chloroform, and in volatile oils; soluble with opalescence in fixed oils.

Captopril: White to off-white, crystalline powder, which may have a characteristic, sulfide-like odor. Melts in the range of 104° to 110°. Freely soluble in water, in methanol, in alcohol, and in chloroform.

Caramel: Thick, dark brown liquid having the characteristic odor of burnt sugar, and a pleasant, bitter taste. One part dissolved in 1000 parts of water yields a clear solution having a distinct yellowish-orange color. The color of this solution is not changed and no precipitate is formed after exposure to sunlight for 6 hours. When spread in a thin layer on a glass plate, it appears homogeneous, reddish-brown, and transparent. Miscible with water. Soluble in dilute alcohol up to 55% (v/v). Immiscible with ether, with chloroform, with acetone, with benzene, and with solvent hexane. *NF category:* Color.

Carbachol: White powder. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in chloroform and in ether.

Carbamazepine: White to off-white powder. Soluble in alcohol and in acetone; practically insoluble in water.

Carbamide Peroxide Topical Solution: Clear, colorless, viscous liquid, having a characteristic odor and taste.

Carbenicillin Disodium: White to off-white, crystalline powder. Freely soluble in water; soluble in alcohol; practically insoluble in chloroform and in ether.

Carbenicillin Indanyl Sodium: White to off-white powder. Soluble in water and in alcohol.

Carbidopa: White to creamy white, odorless or practically odorless, powder. Freely soluble in 3 N hydrochloric acid; slightly soluble in water, and in methanol; practically insoluble in alcohol, in acetone, in chloroform, and in ether.

Carbinoxamine Maleate: White, odorless, crystalline powder. Very soluble in water; freely soluble in alcohol and in chloroform; very slightly soluble in ether.

Carbol-Fuchsin Topical Solution: Dark purple liquid, which appears purplish red when spread in a thin film.

Carbomer 910: White, fluffy powder, having a slight, characteristic odor. Is hygroscopic. The pH of a 1 in 100 dispersion is about 3. When neutralized with alkali hydroxides or with amines, it dissolves in water, in alcohol, and in glycerin. *NF category:* Suspending and/or viscosity-increasing agent.

Carbomer 934: See *Carbomer 910*.

Carbomer 934P: See *Carbomer 910*.

Carbomer 940: See *Carbomer 910*.

Carbomer 941: See *Carbomer 910*.

Carbomer 1342: See *Carbomer 910*.

Carbomer Copolymer: White, hygroscopic powder. It swells in water when a dispersion of it is neutralized with

sodium hydroxide to a pH within the range of 7.3 to 7.8. *NF category:* Emulsifying and/or solubilizing agent; suspending and/or viscosity increasing agent; tablet binder.

Carbomer Homopolymer: White, fluffy hygroscopic powder, having a slight, characteristic odor. The pH of a 1 in 100 dispersion in water is about 3. When neutralized with alkali hydroxides or with amines, it swells giving the appearance of dissolving in water; when neutralized with lower amines and alkanolamines, it swells giving the appearance of dissolving in methanol or glycerin; when neutralized with ethoxylated long-chain (C_{14} – C_{18}) amines, it swells giving the appearance of dissolving in ethanol. *NF category:* Tablet binder; suspending and/or viscosity-increasing agent.

Carbomer Interpolymer: White, hygroscopic powder. It swells in water when a dispersion of it is neutralized with sodium hydroxide to a pH within the range of 5.5 to 9. *NF category:* Emulsifying and/or solubilizing agent; suspending and/or viscosity increasing agent; tablet binder.

Carbon Dioxide: Odorless, colorless gas. Its solutions are acid to litmus. One L at 0° and at a pressure of 760 mm of mercury weighs 1.977 g. One volume dissolves in about 1 volume of water. *NF category:* Air displacement.

Carboprost Tromethamine: White to off-white powder. Soluble in water.

Carboxymethylcellulose Calcium: White to yellowish-white powder. Is hygroscopic. Practically insoluble in alcohol, in acetone, in ether, in chloroform, and in benzene. It swells with water to form a suspension; the pH of the suspension, obtained by shaking 1 g with 100 mL of water, is between 4.5 and 6.0. *NF category:* Suspending and/or viscosity-increasing agent.

Carboxymethylcellulose Sodium: White to cream-colored powder or granules. The powder is hygroscopic. Is easily dispersed in water to form colloidal solutions. Insoluble in alcohol, in ether, and in most other organic solvents. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; tablet binder.

Carboxymethylcellulose Sodium 12: Colorless or white to off-white powder or granules. Is odorless. Water solubility depends on degree of substitution (easily dispersed in water at all temperatures, forming a clear, colloidal solution). Insoluble in acetone, in alcohol, in ether, and in toluene. *NF category:* Suspending and/or viscosity-increasing agent.

Enzymatically-Hydrolyzed Carboxymethylcellulose Sodium: White or slightly yellowish or grayish, odorless, slightly hygroscopic granular or fibrous powder. Soluble in water; insoluble in alcohol. *NF category:* Coating agent; suspending and/or viscosity-increasing agent.

Low-Substituted Carboxymethylcellulose Sodium: A white or almost white powder or short fibers. Practically insoluble in acetone, in alcohol, and in toluene. It swells in water to form a gel.

Carisoprodol: White, crystalline powder, having a mild, characteristic odor and a bitter taste. Freely soluble in alcohol, in chloroform, and in acetone; very slightly soluble in water.

Carmellose: White powder. Practically insoluble in ethanol (99.5%). Swells with water to form a suspension. Becomes viscous in sodium hydroxide TS. Is hygroscopic. *NF category:* Suspending and/or viscosity increasing agent.

Carmustine: Light yellow powder. Freely soluble in ether.

Carprofen: White crystalline powder. Freely soluble in ether, in acetone, in ethyl acetate, and in sodium hydroxide TS or sodium carbonate TS; practically insoluble in water.

Carrageenan: Yellowish or tan to white, coarse to fine powder. Is practically odorless and has a mucilaginous taste. Soluble in water at a temperature of about 80°, forming a viscous, clear or slightly opalescent solution that flows readily. Disperses in water more readily if first moistened with alcohol, with glycerin, or with a saturated solution of su-

crose in water. *NF category:* Suspending and/or viscosity-increasing agent.

Carvedilol: White or nearly white, crystalline powder. Slightly soluble in alcohol; practically insoluble in water and in dilute acids.

Casanthranol: Light tan to brown, amorphous, hygroscopic powder. Freely soluble in water, with some residue; partially soluble in methanol and in hot isopropyl alcohol; practically insoluble in acetone.

Cascara Sagrada: Has a distinct odor and a bitter and slightly acid taste.

Castor Oil: Pale yellowish or almost colorless, transparent, viscid liquid. Has a faint, mild odor; is free from foreign and rancid odor; and has a bland, characteristic taste. Soluble in alcohol. Miscible with dehydrated alcohol, with glacial acetic acid, with chloroform, and with ether. *NF category:* Plasticizer.

Hydrogenated Castor Oil: White, crystalline wax. Insoluble in water and in most common organic solvents. *NF category:* Stiffening agent.

Cefaclor: White to off-white, crystalline powder. Slightly soluble in water; practically insoluble in methanol, in chloroform, and in benzene.

Cefadroxil: White to off-white, crystalline powder. Slightly soluble in water; practically insoluble in alcohol, in chloroform, and in ether.

Cefamandole Nafate: White, odorless, crystalline solid. Soluble in water and in methanol; practically insoluble in ether, in chloroform, in benzene, and in cyclohexane.

Cefazolin: White to slightly off-white, odorless, crystalline powder. Melts at about 198° to 200°, with decomposition. Soluble in dimethylformamide and in pyridine; sparingly soluble in acetone; slightly soluble in alcohol, in methanol, and in water; very slightly soluble in ethyl acetate, in isopropyl alcohol, and in methyl isobutyl ketone; practically insoluble in benzene, in chloroform, in ether, and in methylene chloride.

Cefazolin Sodium: White to off-white, practically odorless, crystalline powder, or white to off-white solid. Freely soluble in water, in saline TS, and in dextrose solutions; very slightly soluble in alcohol; practically insoluble in chloroform and in ether.

Cefdinir: White to light-yellow crystalline powder. Sparingly soluble in 0.1 M phosphate buffer (pH 7) solution; practically insoluble in water, in alcohol, and in diethyl ether.

Cefepime Hydrochloride: White to off-white, crystalline, nonhygroscopic solid. Freely soluble in water.

Cefepime for Injection: White to pale yellow powder. Freely soluble in water.

Cefixime: White to light yellow, crystalline powder. Soluble in methanol and in propylene glycol; slightly soluble in alcohol, in acetone, and in glycerin; very slightly soluble in 70% sorbitol and in octanol; practically insoluble in ether, in ethyl acetate, in hexane, and in water.

Cefmenoxime Hydrochloride: White to light orange-yellow crystals or crystalline powder. Freely soluble in formamide; slightly soluble in methanol; very slightly soluble in water; practically insoluble in dehydrated alcohol and in ether.

Cefmetazole Sodium: White solid. Very soluble in water and in methanol; soluble in acetone; practically insoluble in chloroform.

Cefonicid Sodium: White to off-white solid. Freely soluble in water, in 0.9% sodium chloride solution, and in 5% dextrose solution; soluble in methanol; very slightly soluble in dehydrated alcohol.

Cefoperazone Sodium: White to pale buff crystalline powder. Freely soluble in water; soluble in methanol; slightly soluble in dehydrated alcohol; insoluble in acetone, in ethyl acetate, and in ether.

Ceforanide: White to off-white powder. Very soluble in 1 N sodium hydroxide; practically insoluble in water, in methanol, in chloroform, and in ether.

Cefotaxime Sodium: Off-white to pale yellow crystalline powder. Freely soluble in water; practically insoluble in organic solvents.

Cefoxitin Sodium: White to off-white, granules or powder, having a slight characteristic odor. Is somewhat hygroscopic. Very soluble in water; soluble in methanol; sparingly soluble in dimethylformamide; slightly soluble in acetone; insoluble in ether and in chloroform.

Cefpodoxime Proxetil: White to light brownish-white powder. Odorless or having a faint odor, and has a bitter taste. Freely soluble in dehydrated alcohol; soluble in acetonitrile and in methanol; slightly soluble in ether; very slightly soluble in water.

Ceftazidime: White to cream-colored, crystalline powder. Soluble in alkali and in dimethyl sulfoxide; slightly soluble in dimethylformamide, in methanol, and in water; insoluble in acetone, in alcohol, in chloroform, in dioxane, in ether, in ethyl acetate, and in toluene.

Ceftizoxime Sodium: White to pale yellow crystalline powder. Freely soluble in water.

Ceftriaxone Sodium: White to yellowish-orange crystalline powder. Freely soluble in water; sparingly soluble in methanol; very slightly soluble in alcohol.

Cefuroxime Axetil: White to almost white powder. The amorphous form is freely soluble in acetone; soluble in chloroform, in ethyl acetate, and in methanol; slightly soluble in dehydrated alcohol; insoluble in ether and in water. The crystalline form is freely soluble in acetone; sparingly soluble in chloroform, in ethyl acetate, and in methanol; slightly soluble in dehydrated alcohol; insoluble in ether and in water.

Cefuroxime Sodium: White or faintly yellow powder. Freely soluble in water; soluble in methanol; very slightly soluble in alcohol, in ether, in ethyl acetate, and in chloroform.

Celecoxib: White or almost white, crystalline or amorphous powder. Soluble to freely soluble in ethanol; soluble in methylene chloride; practically insoluble in water.

Cellulurate: Fine white or almost white powder or granules. Available in a range of viscosities, acetyl and butyl contents. Slightly hygroscopic; soluble in acetone, in methylene chloride, in pyridine, and in dimethyl sulfoxide; practically insoluble in water and in alcohol. *NF category:* Coating agent; polymer membrane.

Cellacefate: Free-flowing, white powder. May have a slight odor of acetic acid. Soluble in acetone and in dioxane; insoluble in water and in alcohol. *NF category:* Coating agent.

Cellulose Acetate: Fine, white powder or free-flowing pellets. Available in a range of viscosities and acetyl contents. High viscosity, which reflects high molecular weight, decreases solubility slightly. High acetyl content cellulose acetates generally have more limited solubility in commonly used organic solvents than low acetyl content cellulose acetates, but are more soluble in methylene chloride. All acetyl content cellulose acetates are soluble in dioxane and in dimethylformamide; insoluble in alcohol and in water. *NF category:* Coating agent; polymer membrane.

Microcrystalline Cellulose: Fine, white or almost white powder. It consists of free-flowing, nonfibrous particles. Practically insoluble in sodium hydroxide solution (1 in 20); insoluble in water, in dilute acids, and in most organic solvents. *NF category:* Tablet binder; tablet disintegrant; tablet and/or capsule diluent.

Silicified Microcrystalline Cellulose: White or almost white, very fine to moderately fine powder. It is a free-flowing material that may be compacted into self-binding tablets that disintegrate rapidly in water. Slightly soluble in sodium hydroxide solution (1 in 20); practically insoluble in

water, in acetone, in ethanol, in toluene, and in diluted acid. *NF category:* Tablet binder; tablet disintegrant; tablet and/or capsule diluent.

Microcrystalline Cellulose and Carboxymethylcellulose Sodium: Tasteless, odorless, white to off-white, coarse to fine powder. Swells in water, producing, when dispersed, a white, opaque dispersion or gel. Insoluble in organic solvents and in dilute acids. *NF category:* Suspending and/or viscosity-increasing agent.

Oxidized Cellulose: In the form of gauze or lint. Is slightly off-white in color, is acidic to the taste, and has a slight, charred odor. Soluble in dilute alkalies; insoluble in water and in acids.

Oxidized Regenerated Cellulose: A knit fabric, usually in the form of sterile strips. Slightly off-white, having a slight odor. Soluble in dilute alkalies; insoluble in water and in dilute acids.

Powdered Cellulose: White or almost white powder. Exhibits degrees of fineness ranging from a free-flowing dense powder to a coarse, fluffy, nonflowing material. Slightly soluble in sodium hydroxide solution (1 in 20); insoluble in water, in dilute acids, and in nearly all organic solvents. *NF category:* Filtering aid; sorbent; tablet and/or capsule diluent.

Cellulose Sodium Phosphate: Free-flowing cream-colored, odorless, tasteless powder. Insoluble in water, in dilute acids, and in most organic solvents.

Cephalexin: White to off-white, crystalline powder. Slightly soluble in water; practically insoluble in alcohol, in chloroform, and in ether.

Cephalexin Hydrochloride: White to off-white, crystalline powder. Soluble to the extent of 10 mg per mL in water, in acetone, in acetonitrile, in alcohol, in dimethylformamide, and in methanol; practically insoluble in chloroform, in ether, in ethyl acetate, and in isopropyl alcohol.

Cephalothin Sodium: White to off-white, practically odorless, crystalline powder. Freely soluble in water, in saline TS, and in dextrose solutions; insoluble in most organic solvents.

Cephapirin Benzathine: White, crystalline powder. Soluble in 0.1 N hydrochloric acid; practically insoluble in water, in ether, and in toluene; insoluble in alcohol.

Cephapirin Sodium: White to off-white, crystalline powder, odorless or having a slight odor. Very soluble in water; insoluble in most organic solvents.

Cephradine: White to off-white, crystalline powder. Sparingly soluble in water; very slightly soluble in alcohol and in chloroform; practically insoluble in ether.

Cetirizine Hydrochloride: White to almost white powder. Freely soluble in water; practically insoluble in acetone and in methylene chloride.

Cetostearyl Alcohol: Unctuous, white flakes or granules, having a faint, characteristic odor, and a bland, mild taste. Soluble in alcohol and in ether; insoluble in water. *NF category:* Stiffening agent.

Cetrimonium Bromide: A white to creamy white, voluminous, free-flowing powder, with a characteristic faint odor and bitter, soapy taste. Freely soluble in water and in alcohol; practically insoluble in ether. *NF category:* Antimicrobial preservative.

Cetyl Alcohol: Unctuous, white flakes, granules, cubes, or castings. Has a faint characteristic odor and a bland, mild taste. Usually melts in the range between 45° and 50°. Soluble in alcohol and in ether, the solubility increasing with an increase in temperature; insoluble in water. *NF category:* Stiffening agent.

Cetyl Esters Wax: White to off-white, somewhat translucent flakes, having a crystalline structure and a pearly luster when caked. Has a faint odor and a bland, mild taste, free from rancidity, and has a specific gravity of about 0.83 at 50°. Soluble in boiling alcohol, in ether, in chloroform,

and in fixed and volatile oils; slightly soluble in cold solvent hexane; practically insoluble in cold alcohol; insoluble in water. *NF category:* Stiffening agent.

Cetyl Palmitate: White crystals or flakes. Freely soluble in alcohol and in ether; practically insoluble in water. *NF category:* Stiffening agent.

Cetylpyridinium Chloride: White powder, having a slight, characteristic odor. Very soluble in water, in alcohol, and in chloroform; slightly soluble in benzene and in ether. *NF category:* Antimicrobial preservative; wetting and/or solubilizing agent.

Cetylpyridinium Chloride Topical Solution: Clear liquid. Is colorless unless a color has been added; has an aromatic odor and a bitter taste.

Activated Charcoal: Fine, black, odorless, tasteless powder, free from gritty matter. *NF category:* Sorbent.

Chitosan: White or almost white powder or granules. Soluble in aqueous solutions of glycolic acid, of formic acid, of acetic acid, of hydrochloric acid, and of lactic acid; practically insoluble in organic solvents and in water. *NF category:* Coating agent; film-forming agent; suspending and/or viscosity-increasing agent; vehicle (solid carrier).

Chloral Hydrate: Colorless, transparent, or white crystals having an aromatic, penetrating, and slightly acrid odor, and a slightly bitter, caustic taste. Melts at about 55°, and slowly volatilizes when exposed to air. Very soluble in water and in olive oil; freely soluble in alcohol, in chloroform, and in ether.

Chlorambucil: Off-white, slightly granular powder. Freely soluble in acetone; soluble in dilute alkali; very slightly soluble in water.

Chloramphenicol: Fine, white to grayish-white or yellowish-white, needle-like crystals or elongated plates. Its solutions are practically neutral to litmus. Is reasonably stable in neutral or moderately acid solutions. Its alcohol solution is dextrorotatory and its ethyl acetate solution is levorotatory. Freely soluble in alcohol, in propylene glycol, in acetone, and in ethyl acetate; slightly soluble in water.

Chloramphenicol Palmitate: Fine, white, unctuous, crystalline powder, having a faint odor and a bland, mild taste. Freely soluble in acetone and in chloroform; soluble in ether; sparingly soluble in alcohol; very slightly soluble in solvent hexane; insoluble in water.

Chloramphenicol Sodium Succinate: Light yellow powder. Freely soluble in water and in alcohol.

Chlordiazepoxide: Yellow, practically odorless, crystalline powder. Is sensitive to sunlight. Melts at about 240°. Sparingly soluble in chloroform and in alcohol; insoluble in water.

Chlordiazepoxide Hydrochloride: White or practically white, odorless, crystalline powder. Is affected by sunlight. Soluble in water; sparingly soluble in alcohol; insoluble in solvent hexane.

Chlorhexidine Acetate: A white or almost white, microcrystalline powder. Soluble in alcohol; sparingly soluble in water; slightly soluble in glycerol and in propylene glycol.

Chlorhexidine Gluconate Solution: Almost colorless or pale yellow, clear liquid. Miscible with glacial acetic acid and with water; miscible with three times its volume of acetone and with five times its volume of dehydrated alcohol; further addition of acetone or dehydrated alcohol yields a white turbidity.

Chlorhexidine Hydrochloride: White or almost white, crystalline powder. Sparingly soluble in propylene glycol and in water; very slightly soluble in alcohol.

Chlorobutanol: Colorless to white crystals, having a characteristic, somewhat camphoraceous, odor and taste. Anhydrous form melts at about 95°, and hydrous form melts at about 76°. Freely soluble in alcohol, in ether, in chloroform, and in volatile oils; soluble in glycerin; slightly soluble in water. *NF category:* Antimicrobial preservative.

Chlorocresol: Colorless or practically colorless crystals or crystalline powder, having a characteristic, nontarry odor. Is volatile in steam. Very soluble in alcohol; soluble in ether, in terpenes, in fixed oils, and in solutions of alkali hydroxides; slightly soluble in water and more soluble in hot water. *NF category:* Antimicrobial preservative.

Chloroprocaine Hydrochloride: White, crystalline powder. Is odorless, and is stable in air. Its solutions are acid to litmus. Exhibits local anesthetic properties when placed upon the tongue. Soluble in water; slightly soluble in alcohol; very slightly soluble in chloroform; practically insoluble in ether.

Chloroquine: White or slightly yellow, crystalline powder. Is odorless, and has a bitter taste. Soluble in dilute acids, in chloroform, and in ether; very slightly soluble in water.

Chloroquine Hydrochloride Injection: Colorless liquid.

Chloroquine Phosphate: White, crystalline powder. Is odorless, has a bitter taste, and is discolored slowly on exposure to light. Its solutions have a pH of about 4.5. Exists in two polymorphic forms, one melting between 193° and 195° and the other between 210° and 215° (see *Melting Range or Temperature* (741)); mixture of the forms melts between 193° and 215°. Freely soluble in water; practically insoluble in alcohol, in chloroform, and in ether.

Chlorothiazide: White or practically white, crystalline, odorless powder. Melts at about 340°, with decomposition. Freely soluble in dimethylformamide and in dimethyl sulfoxide; slightly soluble in methanol and in pyridine; practically insoluble in ether, in benzene, and in chloroform; very slightly soluble in water.

Chloroxylenol: White crystals or crystalline powder, having a characteristic odor. Is volatile in steam. Freely soluble in alcohol, in ether, in terpenes, in fixed oils, and in solutions of alkali hydroxides; very slightly soluble in water.

Chlorpheniramine Maleate: White, odorless, crystalline powder. Its solutions have a pH between 4 and 5. Freely soluble in water; soluble in alcohol and in chloroform; slightly soluble in ether and in benzene.

Chlorpromazine: White, crystalline solid, having an amine-like odor. Darkens on prolonged exposure to light. Melts at about 60°. Freely soluble in alcohol, in benzene, in chloroform, in ether, and in dilute mineral acids; practically insoluble in water and in dilute alkali hydroxides.

Chlorpromazine Hydrochloride: White or slightly creamy white, odorless, crystalline powder. Darkens on prolonged exposure to light. Very soluble in water; freely soluble in alcohol and in chloroform; insoluble in ether and in benzene.

Chlorpropamide: White, crystalline powder, having a slight odor. Soluble in alcohol; sparingly soluble in chloroform; practically insoluble in water.

Chlortetracycline Hydrochloride: Yellow, crystalline powder. Is odorless, and has a bitter taste. Is stable in air, but is slowly affected by light. Soluble in solutions of alkali hydroxides and carbonates; sparingly soluble in water; slightly soluble in alcohol; practically insoluble in acetone, in chloroform, in dioxane, and in ether.

Chlorthalidone: White to yellowish-white, crystalline powder. Melts at a temperature above 215°, with decomposition. Soluble in methanol; slightly soluble in alcohol; practically insoluble in water, in ether, and in chloroform.

Chlorzoxazone: White or practically white, practically odorless, crystalline powder. Soluble in solutions of alkali hydroxides and ammonia; sparingly soluble in alcohol, in isopropyl alcohol, and in methanol; slightly soluble in water.

Cholecalciferol: White, odorless crystals. Is affected by air and by light. Melts at about 85°. Soluble in alcohol, in chloroform, and in fatty oils; insoluble in water.

Cholesterol: White or faintly yellow, practically odorless, pearly leaflets, needles, powder, or granules. Ac-

quires a yellow to pale tan color on prolonged exposure to light. Soluble in acetone, in chloroform, in dioxane, in ether, in ethyl acetate, in solvent hexane, and in vegetable oils; sparingly soluble in dehydrated alcohol; slightly (and slowly) soluble in alcohol; insoluble in water. *NF category:* Emulsifying and/or solubilizing agent.

Cholestyramine Resin: White to buff-colored, hygroscopic, fine powder. Is odorless or has not more than a slight amine-like odor. Insoluble in water, in alcohol, in chloroform, and in ether.

Choline Bitartrate: White, hygroscopic, crystalline powder. Clear, colorless liquid in solution. Melts between 148° and 153°. Is odorless, or may have a faint trimethylamine odor. Freely soluble in water; slightly soluble in alcohol; insoluble in ether and in chloroform.

Choline Chloride: Colorless or white crystals or crystalline powder, usually having a slight odor of trimethylamine. Clear and colorless in solution. Hygroscopic. Soluble in alcohol and in water.

Sodium Chromate Cr 51 Injection: Clear, slightly yellow solution.

Chromic Chloride: Dark green, odorless, slightly deliquescent crystals. Soluble in water and in alcohol; slightly soluble in acetone; practically insoluble in ether.

Chymotrypsin: White to yellowish-white, crystalline or amorphous, odorless, powder. An amount equivalent to 100,000 USP Units is soluble in 10 mL of water and in 10 mL of saline TS.

Ciclopirox: White to slightly yellowish-white, crystalline powder. Freely soluble in ethanol and in methylene chloride; soluble in ether; slightly soluble in water.

Ciclopirox Olamine: White to slightly yellowish-white, crystalline powder. Very soluble in alcohol and in methylene chloride; slightly soluble in water; practically insoluble in cyclohexane.

Cilastatin Sodium: White to tan-colored powder. Soluble in water and in methanol.

Cilostazol: White to off-white crystals. Freely soluble in chloroform; slightly soluble in methanol and in alcohol; practically insoluble in water.

Cimetidine: White to off-white, crystalline powder; odorless, or having a slight mercaptan odor. Freely soluble in methanol; soluble in alcohol and in polyethylene glycol 400; sparingly soluble in isopropyl alcohol; slightly soluble in water and in chloroform; practically insoluble in ether.

Cinoxacin: White to yellowish-white, crystalline solid. Is odorless, and has a bitter taste and a lingering aftertaste. Soluble in alkaline solution; insoluble in water and in most common organic solvents.

Ciprofloxacin Hydrochloride: Faintly yellowish to light yellow crystals. Sparingly soluble in water; slightly soluble in acetic acid and in methanol; very slightly soluble in dehydrated alcohol; practically insoluble in acetone, in acetonitrile, in ethyl acetate, in hexane, and in methylene chloride.

Cisapride: White or almost white powder. Freely soluble in dimethylformamide; soluble in methylene chloride; sparingly soluble in methanol; practically insoluble in water.

Change to read:

Citalopram Hydrobromide: White to almost white, crystalline powder. Soluble in alcohol; sparingly soluble in water ▲ and in dehydrated alcohol.▲ *USP36*

Anhydrous Citric Acid: Colorless, translucent crystals, or white, granular to fine, crystalline powder. Melts at about 153°, with decomposition. Very soluble in water; freely soluble in alcohol; very slightly soluble in ether. *NF category:* Acidifying agent; buffering agent.

Citric Acid Monohydrate: Colorless, translucent crystals, or white, granular to fine, crystalline powder. Efflores-

cent in dry air. Very soluble in water; freely soluble in alcohol; very slightly soluble in ether. *NF category:* Acidifying agent; buffering agent.

Clarithromycin: White to off-white, crystalline powder. Soluble in acetone; slightly soluble in dehydrated alcohol, in methanol, and in acetonitrile, and in phosphate buffer at pH values of 2 to 5; practically insoluble in water.

Clavulanate Potassium: White to off-white powder. Is moisture-sensitive. Freely soluble in water, but stability in aqueous solution is not good, optimum stability at a pH of 6.0 to 6.3; soluble in methanol, with decomposition.

Clemastine Fumarate: White to off-white, odorless powder. Its solutions are acid to litmus. Slightly soluble in methanol; very slightly soluble in water, and in chloroform.

Clenbuterol Hydrochloride: White or almost white, crystalline powder. Soluble in water and in alcohol; slightly soluble in acetone. It melts with decomposition at 173°.

Clidinium Bromide: White to nearly white, practically odorless, crystalline powder. Is optically inactive. Melts at about 242°. Soluble in water and in alcohol; slightly soluble in benzene and in ether.

Clindamycin Hydrochloride: White or practically white, crystalline powder. Is odorless or has a faint mercaptan-like odor. Is stable in the presence of air and light. Its solutions are acidic and are dextrorotatory. Freely soluble in water, in dimethylformamide, and in methanol; soluble in alcohol; practically insoluble in acetone.

Clindamycin Palmitate Hydrochloride: White to off-white amorphous powder, having a characteristic odor. Very soluble in ethyl acetate and in dimethylformamide; freely soluble in water, in benzene, in ether, in chloroform, and in alcohol.

Clindamycin Phosphate: White to off-white, hygroscopic, crystalline powder. Is odorless or practically odorless, and has a bitter taste. Freely soluble in water; slightly soluble in dehydrated alcohol; very slightly soluble in acetone; practically insoluble in chloroform, in benzene, and in ether.

Clioquinol: Voluminous, spongy, yellowish-white to brownish-yellow powder, having a slight, characteristic odor. Darkens on exposure to light. Melts at about 180°, with decomposition. Soluble in hot ethyl acetate and in hot glacial acetic acid; practically insoluble in water and in alcohol.

Clobetasol Propionate: White to cream, crystalline powder. Soluble in acetone, in dimethyl sulfoxide, in chloroform, in methanol, and in dioxane; sparingly soluble in ethanol; slightly soluble in benzene and in diethyl ether; practically insoluble in water.

Clocortolone Pivalate: White to yellowish-white, odorless powder. Melts at about 230°, with decomposition. Freely soluble in chloroform and in dioxane; soluble in acetone; sparingly soluble in alcohol; slightly soluble in benzene and in ether.

Clofazimine: Dark red crystals. Melts at about 217°, with decomposition. Soluble in chloroform and in benzene; sparingly soluble in alcohol, in acetone, and in ethyl acetate; practically insoluble in water.

Clofibrate: Colorless to pale yellow liquid having a characteristic odor. Soluble in acetone, in alcohol, in benzene, and in chloroform; insoluble in water.

Clomiphene Citrate: White to pale yellow, essentially odorless powder. Freely soluble in methanol; sparingly soluble in alcohol; slightly soluble in water and in chloroform; insoluble in ether.

Clomipramine Hydrochloride: White to faintly yellow, crystalline powder. Very soluble in water.

Clonazepam: Light yellow powder, having a faint odor. Sparingly soluble in acetone and in chloroform; slightly soluble in alcohol and in ether; insoluble in water.

Clonidine: White to almost white, crystalline powder. Melting point is about 130°. Freely soluble in methanol and in alcohol.

Change to read:

Clopidogrel Bisulfate: White to off-white powder.

▲ Freely soluble at pH 1; practically insoluble at neutral pH. ▲ *USP36*

Cloprostenol Sodium: White or almost white, amorphous powder. Is hygroscopic. Freely soluble in water, in alcohol, and in methanol; practically insoluble in acetone.

Clorazepate Dipotassium: Light yellow, crystalline powder. Darkens on exposure to light. Soluble in water but, upon standing, may precipitate from the solution; slightly soluble in alcohol and in isopropyl alcohol; practically insoluble in acetone, in benzene, in chloroform, in ether, and in methylene chloride.

Clorsulon: White to off-white powder. Freely soluble in acetonitrile and in methanol; slightly soluble in water; very slightly soluble in methylene chloride.

Clotrimazole: White to pale yellow, crystalline powder. Melts at about 142°, with decomposition. Freely soluble in methanol, in acetone, in chloroform, and in alcohol; practically insoluble in water.

Cloxacillin Benzathine: White or almost white, almost odorless, crystals or crystalline powder. Soluble in chloroform and in methanol; sparingly soluble in acetone; slightly soluble in water, in alcohol, and in isopropyl alcohol.

Cloxacillin Sodium: White, odorless, crystalline powder. Freely soluble in water; soluble in alcohol; slightly soluble in chloroform.

Clozapine: Yellow, crystalline powder. Soluble in chloroform, in acetone, and in alcohol; sparingly soluble in acetonitrile; insoluble in water.

Coal Tar: Nearly black, viscous liquid, heavier than water, having a characteristic, naphthalene-like odor, and producing a sharp, burning sensation on the tongue. Slightly soluble in water, to which it imparts its characteristic odor and taste and a faintly alkaline reaction; partially soluble in acetone, in alcohol, in carbon disulfide, in chloroform, in ether, in methanol, and in solvent hexane; soluble in benzene and nitrobenzene.

Cyanocobalamin Co 57 Capsules: May contain a small amount of solid or solids, or may appear empty.

Cyanocobalamin Co 57 Oral Solution: Clear, colorless to pink solution.

Cocaine: Colorless to white crystals or white, crystalline powder. Is levorotatory in 3 N hydrochloric acid solution. Its saturated solution is alkaline to litmus. Very soluble in warm alcohol; freely soluble in alcohol, in chloroform, and in ether; soluble in olive oil; sparingly soluble in mineral oil; slightly soluble in water.

Cocaine Hydrochloride: Colorless crystals or white, crystalline powder. Very soluble in water; freely soluble in alcohol; soluble in chloroform and in glycerin; insoluble in ether.

Coccidioidin: Clear, practically colorless or amber-colored liquid.

Cocoa Butter: Yellowish-white solid, having a faint, agreeable odor, and a bland, chocolate-like taste if the cocoa butter is obtained by pressing. If obtained by extraction, the taste is bland. Is usually brittle at temperatures below 25°. Freely soluble in ether and in chloroform; soluble in boiling dehydrated alcohol; slightly soluble in alcohol. *NF category:* Suppository base.

Coconut Oil: Clear, white to light yellow-tan, viscous liquid. Freely soluble in methylene chloride and in light petroleum (bp: 65° to 70°); very slightly soluble in alcohol;

practically insoluble in water. *NF category:* Coating agent; emulsifying and/or solubilizing agent.

Hydrogenated Coconut Oil: White to yellowish, fatty solid to semi-solid. Freely soluble in ether; very slightly soluble in alcohol; practically insoluble in water. *NF category:* Coating agent; tablet binder; tablet and/or capsule lubricant.

Cod Liver Oil: Thin, oily liquid, having a characteristic, slightly fishy but not rancid odor, and a fishy taste. Freely soluble in ether, in chloroform, in carbon disulfide, and in ethyl acetate; slightly soluble in alcohol.

Codeine: Colorless or white crystals or white, crystalline powder. It effloresces slowly in dry air, and is affected by light. In acid or alcohol solutions it is levorotatory. Its saturated solution is alkaline to litmus. Very soluble in chloroform; freely soluble in alcohol; sparingly soluble in ether; slightly soluble in water. When heated in an amount of water insufficient for complete solution, it melts to oily drops that crystallize on cooling.

Codeine Phosphate: Fine, white, needle-shaped crystals, or white, crystalline powder. Is odorless. Is affected by light. Its solutions are acid to litmus. Very soluble in hot water; freely soluble in water; slightly soluble in alcohol but more so in boiling alcohol.

Codeine Sulfate: White crystals, usually needle-like, or white, crystalline powder. Is affected by light. Freely soluble in water at 80°; soluble in water; very slightly soluble in alcohol; insoluble in chloroform and in ether.

Colchicine: Pale yellow to pale greenish-yellow, amorphous scales, or powder or crystalline powder. Is odorless or nearly so, and darkens on exposure to light. Freely soluble in alcohol and in chloroform; soluble in water; slightly soluble in ether.

Colestipol Hydrochloride: Yellow to orange beads. Swells but does not dissolve in water or dilute aqueous solutions of acid or alkali. Insoluble in the common organic solvents.

Colistimethate Sodium: White to slightly yellow, odorless, fine powder. Freely soluble in water; soluble in methanol; insoluble in acetone and in ether.

Colistin Sulfate: White to slightly yellow, odorless, fine powder. Freely soluble in water; slightly soluble in methanol; insoluble in acetone and in ether.

Collodion: Clear, or slightly opalescent, viscous liquid. Is colorless, or slightly yellowish, and has the odor of ether.

Flexible Collodion: Clear, or slightly opalescent, viscous liquid. Is colorless or slightly yellow, and has the odor of ether. The strong odor of camphor becomes noticeable as the ether evaporates.

Copovidone: White to yellowish-white powder or flakes. Is hygroscopic. Freely soluble in water, in alcohol, and in methylene chloride; practically insoluble in ether. *NF category:* Tablet binder; coating agent.

Corn Oil: Clear, light yellow, oily liquid, having a faint, characteristic odor and taste. Slightly soluble in alcohol. Miscible with ether, with chloroform, with benzene, and with solvent hexane. *Specific gravity* (841): Between 0.914 and 0.921. *NF category:* Solvent; vehicle (oleaginous).

Corn Syrup: Clear, white to light yellow, viscous liquid. Is miscible in all proportions with water. *NF category:* Suspending and/or viscosity-increasing agent; sweetening agent; tablet and/or capsule diluent; tablet binder; tonicity agent.

Corn Syrup Solids: Sweet, white to light yellow powder or granules. Soluble in water. *NF category:* Coating agent; flavored and/or sweetened vehicle; humectant; solid carrier; suspending and/or viscosity-increasing agent; sweetening agent; tablet and/or capsule diluent; tablet binder; tonicity agent.

Corticotropin Injection: Colorless or light straw-colored liquid.

Corticotropin for Injection: White or practically white, soluble, amorphous solid having the characteristic appearance of substances prepared by freeze-drying.

Repository Corticotropin Injection: Colorless or light straw-colored liquid, which may be quite viscid at room temperature. Is odorless or has an odor of an antimicrobial agent.

Corticotropin Zinc Hydroxide Injectable Suspension: Flocculent, white, aqueous suspension, free from large particles following moderate shaking.

Cortisone Acetate: White or practically white, odorless, crystalline powder. Is stable in air. Melts at about 240°, with some decomposition (see *Melting Range or Temperature* <741>). Freely soluble in chloroform; soluble in dioxane; sparingly soluble in acetone; slightly soluble in alcohol; insoluble in water.

Purified Cotton: White, soft, fine filament-like hairs appearing under the microscope as hollow, flattened, and twisted bands, striate and slightly thickened at the edges. Is practically odorless and practically tasteless. Soluble in ammoniated cupric oxide TS; insoluble in ordinary solvents.

Cottonseed Oil: Pale yellow, oily liquid. Is odorless or nearly so, and has a bland taste. At temperatures below 10° particles of solid fat may separate from the Oil, and at about 0° to -5° the Oil becomes a solid or nearly so. *Specific gravity* (841): Between 0.915 and 0.921. Slightly soluble in alcohol. Miscible with ether, with chloroform, with solvent hexane, and with carbon disulfide. *NF category:* Solvent; vehicle (oleaginous).

Hydrogenated Cottonseed Oil: A white mass or powder that melts to a clear, pale yellow liquid when heated. Freely soluble in methylene chloride and in toluene; very slightly soluble in alcohol; practically insoluble in water.

Creatinine: White crystals or crystalline powder; odorless. Soluble in water; slightly soluble in alcohol; practically insoluble in acetone, in ether, and in chloroform. *NF category:* Bulking agent for freeze-drying.

Cresol: Colorless, or yellowish to brownish-yellow, or pinkish, highly refractive liquid, becoming darker with age and on exposure to light. Has a phenol-like, sometimes empyreumatic odor. A saturated solution of it is neutral or only slightly acid to litmus. Sparingly soluble in water, usually forming a cloudy solution; dissolves in solutions of fixed alkali hydroxides. Miscible with alcohol, with ether, and with glycerin. *NF category:* Antimicrobial preservative.

Cromolyn Sodium: White, odorless, crystalline powder. Is tasteless at first, with a slightly bitter aftertaste. Is hygroscopic. Soluble in water; insoluble in alcohol and in chloroform.

Cromolyn Sodium for Inhalation: White to creamy white, odorless, hygroscopic, and very finely divided powder.

Croscarmellose Sodium: White, free-flowing powder. Partially soluble in water; insoluble in alcohol, in ether, and in other organic solvents. *NF category:* Tablet disintegrant.

Crospovidone: White to creamy-white, hygroscopic powder, having a faint odor. Insoluble in water and in ordinary organic solvents. *NF category:* Tablet disintegrant.

Crotamiton: Colorless to slightly yellowish oil, having a faint amine-like odor. Soluble in alcohol and in methanol.

Cupric Chloride: Bluish green, deliquescent crystals. Freely soluble in water; soluble in alcohol; slightly soluble in ether.

Cupric Sulfate: Deep blue, triclinic crystals or blue, crystalline granules or powder. It effloresces slowly in dry air. Its solutions are acid to litmus. Very soluble in boiling water; freely soluble in water and in glycerin; slightly soluble in alcohol.

Cyanocobalamin: Dark red crystals or amorphous or crystalline red powder. In the anhydrous form, it is very hygroscopic and when exposed to air it may absorb about

12% of water. Soluble in alcohol; sparingly soluble in water; insoluble in acetone, in chloroform, and in ether.

Cyclandelate: White, crystalline powder. Very soluble in acetonitrile, in alcohol, and in ether; practically insoluble in water. Melts at about 58°.

Cyclizine Hydrochloride: White, crystalline powder or small, colorless crystals. Is odorless or nearly so, and has a bitter taste. Melts indistinctly at about 285°, with decomposition. Sparingly soluble in chloroform; slightly soluble in water and in alcohol; insoluble in ether.

Cyclobenzaprine Hydrochloride: White to off-white, odorless, crystalline powder. Freely soluble in water, in alcohol, and in methanol; sparingly soluble in isopropanol; slightly soluble in chloroform and in methylene chloride; insoluble in hydrocarbons.

Cyclopentolate Hydrochloride: White, crystalline powder, which upon standing develops a characteristic odor. Its solutions are acid to litmus. Melts at about 138°, the melt appearing opaque. Very soluble in water; freely soluble in alcohol; insoluble in ether.

Cyclophosphamide: White, crystalline powder. Liquefies upon loss of its water of crystallization. Soluble in water and in alcohol.

Cyclopropane: Colorless gas having a characteristic odor. Has a pungent taste. One L at a pressure of 760 mm and a temperature of 0° weighs about 1.88 g. One volume dissolves in about 2.7 volumes of water at 15°. Freely soluble in alcohol; soluble in fixed oils.

Cycloserine: White to pale yellow, crystalline powder. Is odorless or has a faint odor. Is hygroscopic and deteriorates upon absorbing water. Its solutions are dextrorotatory. Freely soluble in water.

Cyclosporine: White to almost white powder. Soluble in acetone, in alcohol, in methanol, in ether, in chloroform, and in methylene chloride; slightly soluble in saturated hydrocarbons; practically insoluble in water.

Cyproheptadine Hydrochloride: White to slightly yellow, odorless or practically odorless, crystalline powder. Freely soluble in methanol; soluble in chloroform; sparingly soluble in alcohol; slightly soluble in water; practically insoluble in ether.

Cyromazine: White or off-white, odorless, crystalline powder. Slightly soluble in methanol and in water.

Cysteine Hydrochloride: White crystals or crystalline powder. Soluble in water, in alcohol, and in acetone.

Cytarabine: Odorless, white to off-white, crystalline powder. Freely soluble in water; slightly soluble in alcohol and in chloroform.

Dactinomycin: Bright red, crystalline powder. Is somewhat hygroscopic and is affected by light and by heat. Freely soluble in alcohol; soluble in water at 10° and slightly soluble in water at 37°; very slightly soluble in ether.

Danazol: White to pale yellow, crystalline powder. Melts at about 225°, with some decomposition. Freely soluble in chloroform; soluble in acetone; sparingly soluble in alcohol and in benzene; slightly soluble in ether; practically insoluble or insoluble in water and in hexane.

Change to read:

Dantrolene Sodium: Fine orange to orange-brown powder. Sparingly soluble in ▲ dimethylformamide and in glycerine; sparingly soluble to practically insoluble in acetone.▲ USP36

Dapsone: White or creamy white, crystalline powder. Is odorless and has a slightly bitter taste. Freely soluble in alcohol; soluble in acetone and in dilute mineral acids; very slightly soluble in water.

Daunorubicin Hydrochloride: Orange-red, crystalline, hygroscopic powder. Freely soluble in water and in metha-

nol; slightly soluble in alcohol; very slightly soluble in chloroform; practically insoluble in acetone.

Deferoxamine Mesylate: White to off-white powder. Freely soluble in water; slightly soluble in methanol.

Dehydrocholic Acid: White, fluffy, odorless powder, having a bitter taste. Soluble in glacial acetic acid and in solutions of alkali hydroxides and carbonates; sparingly soluble in chloroform (the solutions in alcohol and in chloroform usually are slightly turbid); slightly soluble in alcohol and in ether; practically insoluble in water.

Dehydroacetic Acid: White or nearly white, crystalline powder. Soluble in aqueous solutions of alkalies; very slightly soluble in water. One g of sample dissolves in about 35 mL of alcohol and in 5 mL of acetone. *NF category:* Antimicrobial preservative.

Demecarium Bromide: White or slightly yellow, slightly hygroscopic, crystalline powder. Freely soluble in water and in alcohol; soluble in ether; sparingly soluble in acetone.

Demeclocycline: Yellow, crystalline, odorless powder, having a bitter taste. Soluble in alcohol; sparingly soluble in water. Dissolves readily in 3 N hydrochloric acid and in alkaline solutions.

Demeclocycline Hydrochloride: Yellow, crystalline, odorless powder, having a bitter taste. Sparingly soluble in water and in solutions of alkali hydroxides and carbonates; slightly soluble in alcohol; practically insoluble in acetone and in chloroform.

Denatonium Benzoate: Very soluble in chloroform and in methanol; freely soluble in water and in alcohol; very slightly soluble in ether. *NF category:* Alcohol denaturant.

Desipramine Hydrochloride: White to off-white, crystalline powder. Melts at about 213°. Freely soluble in methanol and in chloroform; soluble in water and in alcohol; insoluble in ether.

Desmopressin Acetate: White, fluffy powder. Soluble in water, in alcohol, and in acetic acid.

Desoximetasone: White to practically white, odorless, crystalline powder. Freely soluble in alcohol, in acetone, and in chloroform; insoluble in water.

Desoxycholic Acid: Occurs as a white, crystalline powder. Freely soluble in alcohol; soluble in acetone and in solutions of alkali hydroxides and carbonates; slightly soluble in chloroform and in ether; practically insoluble in water. *NF category:* Emulsifying and/or solubilizing agent.

Desoxycorticosterone Acetate: White or creamy white, crystalline powder. Is odorless, and is stable in air. Sparingly soluble in alcohol, in acetone, and in dioxane; slightly soluble in vegetable oils; practically insoluble in water.

Dexamethasone: White to practically white, odorless, crystalline powder. Is stable in air. Melts at about 250°, with some decomposition. Sparingly soluble in acetone, in alcohol, in dioxane, and in methanol; slightly soluble in chloroform; very slightly soluble in ether; practically insoluble in water.

Dexamethasone Acetate: Clear, white to off-white, odorless powder. Freely soluble in methanol, in acetone, and in dioxane; practically insoluble in water.

Dexamethasone Sodium Phosphate: White or slightly yellow, crystalline powder. Is odorless or has a slight odor of alcohol, and is exceedingly hygroscopic. Freely soluble in water; slightly soluble in alcohol; very slightly soluble in dioxane; insoluble in chloroform and in ether.

Dexbrompheniramine Maleate: White, odorless, crystalline powder. Exists in two polymorphic forms, one melting between 106° and 107° and the other between 112° and 113°. Mixtures of the forms may melt between 105° and 113°. The pH of a solution (1 in 100) is about 5. Freely soluble in water; soluble in alcohol and in chloroform.

Dexchlorpheniramine Maleate: White, odorless, crystalline powder. Freely soluble in water; soluble in alcohol and in chloroform; slightly soluble in benzene and in ether.

Dexpanthenol: Clear, viscous, somewhat hygroscopic liquid, having a slight, characteristic odor. Some crystallization may occur on standing. Freely soluble in water, in alcohol, in methanol, and in propylene glycol; soluble in chloroform and in ether; slightly soluble in glycerin.

Dextran 1: A white to off-white powder. Is hygroscopic. Very soluble in water; sparingly soluble in alcohol.

Dextrates: Free-flowing, porous, white, odorless, spherical granules consisting of aggregates of microcrystals, having a sweet taste and producing a cooling sensation in the mouth. May be compressed directly into self-binding tablets. Freely soluble in water (heating increases its solubility in water); soluble in dilute acids and alkalies and in basic organic solvents such as pyridine; insoluble in the common organic solvents. *NF category:* Sweetening agent; tablet and/or capsule diluent.

Dextrin: Free-flowing, white, yellow, or brown powder. Its solubility in water varies; it is usually very soluble, but often contains an insoluble portion. *NF category:* Tablet binder; tablet and/or capsule diluent.

Dextroamphetamine Sulfate: White, odorless, crystalline powder. Soluble in water; slightly soluble in alcohol; insoluble in ether.

Dextromethorphan: Practically white to slightly yellow, odorless, crystalline powder. Eleven mg of Dextromethorphan is equivalent to 15 mg of dextromethorphan hydrobromide monohydrate. Freely soluble in chloroform; practically insoluble in water.

Dextromethorphan Hydrobromide: Practically white crystals or crystalline powder, having a faint odor. Melts at about 126°, with decomposition. Freely soluble in alcohol and in chloroform; sparingly soluble in water; insoluble in ether.

Dextrose: Colorless crystals or white, crystalline or granular powder. Is odorless, and has a sweet taste. Very soluble in boiling water; freely soluble in water; soluble in boiling alcohol; slightly soluble in alcohol. *NF category:* Sweetening agent; tonicity agent; vehicle (flavored and/or sweetened).

Dextrose Excipient: Colorless crystals or white, crystalline or granular powder. Is odorless and sweet-tasting. Very soluble in boiling water; freely soluble in water; sparingly soluble in boiling alcohol; slightly soluble in alcohol. *NF category:* Sweetening agent; tablet and/or capsule diluent.

Diacetylated Monoglycerides: Clear liquid. Very soluble in 80% (w/w) aqueous alcohol, in vegetable oils, and in mineral oils; sparingly soluble in 70% alcohol. *NF category:* Plasticizer.

Diatrizoate Meglumine: White, odorless powder. Freely soluble in water.

Diatrizoate Meglumine Injection: Clear, colorless to pale yellow, slightly viscous liquid.

Diatrizoate Meglumine and Diatrizoate Sodium Injection: Clear, colorless to pale yellow, slightly viscous liquid. May crystallize at room temperature or below.

Diatrizoate Sodium: White, odorless powder. Soluble in water; slightly soluble in alcohol; practically insoluble in acetone and in ether.

Diatrizoate Sodium Injection: Clear, colorless to pale yellow, slightly viscous liquid.

Diatrizoate Sodium Solution: Clear, pale yellow to light brown liquid.

Diatrizoic Acid: White, odorless powder. Soluble in dimethylformamide and in alkali hydroxide solutions; very slightly soluble in water and in alcohol.

Diazepam: Off-white to yellow, practically odorless, crystalline powder. Freely soluble in chloroform; soluble in alcohol; practically insoluble in water.

Diazoxide: White or cream-white crystals or crystalline powder. Very soluble in strong alkaline solutions; freely solu-

ble in dimethylformamide; sparingly soluble to practically insoluble in water and in most organic solvents.

Dibucaine: White to off-white powder, having a slight, characteristic odor. Darkens on exposure to light. Soluble in 1 N hydrochloric acid and in ether; slightly soluble in water.

Dibucaine Hydrochloride: Colorless or white to off-white crystals or white to off-white, crystalline powder. Is odorless, is somewhat hygroscopic, and darkens on exposure to light. Its solutions have a pH of about 5.5. Freely soluble in water, in alcohol, in acetone, and in chloroform.

Dibutyl Phthalate: A clear, oily liquid, colorless or very slightly yellow. Practically insoluble in water. Miscible with alcohol and with ether.

Dibutyl Sebacate: Colorless, oily liquid of very mild odor. Soluble in alcohol, in isopropyl alcohol, and in mineral oil; very slightly soluble in propylene glycol; practically insoluble in water and in glycerin. *NF category:* Plasticizer.

Dichloralphenazone: White, microcrystalline powder. Has a slight odor characteristic of chloral hydrate. Decomposed by dilute alkali, liberating chloroform. Freely soluble in water, in alcohol, and in chloroform; soluble in dilute acids.

Dichlorodifluoromethane: Clear, colorless gas, having a faint, ethereal odor. Its vapor pressure at 25° is about 4880 mm of mercury (80 psig). *NF category:* Aerosol propellant.

Dichlorotetrafluoroethane: Clear, colorless gas, having a faint, ethereal odor. Its vapor pressure at 25° is about 1620 mm of mercury (17 psig). Usually contains between 6% and 10% of its isomer, CCl₂F-CF₃. *NF category:* Aerosol propellant.

Diclazuril: White to yellow powder. Sparingly soluble in dimethylformamide; practically insoluble in water, in alcohol, and in methylene chloride.

Diclofenac Potassium: White to off-white or slightly yellowish crystalline powder, slightly hygroscopic. Freely soluble in methanol; soluble in alcohol; sparingly soluble in water; slightly soluble in acetone.

Diclofenac Sodium: White to off-white, hygroscopic, crystalline powder. Melts at about 284°. Freely soluble in methanol; soluble in ethanol; sparingly soluble in water; practically insoluble in chloroform and in ether.

Dicloxacillin Sodium: White to off-white, crystalline powder. Freely soluble in water.

Dicyclomine Hydrochloride: Fine, white, crystalline powder. Is practically odorless and has a very bitter taste. Freely soluble in alcohol and in chloroform; soluble in water; very slightly soluble in ether.

Dicyclomine Hydrochloride Injection: Colorless solution, which may have the odor of a preservative.

Didanosine: White to off-white, crystalline powder. Very soluble in dimethyl sulfoxide; practically insoluble or insoluble in acetone and in methanol.

Dienestrol: Colorless, white or practically white, needle-like crystals, or white or practically white, crystalline powder. Is odorless. Soluble in alcohol, in acetone, in ether, in methanol, in propylene glycol, and in solutions of alkali hydroxides; slightly soluble in chloroform and in fatty oils; practically insoluble in water.

Diethanolamine: White or clear, colorless crystals, deliquescent in moist air; or colorless liquid. Miscible with water, with alcohol, with acetone, with chloroform, and with glycerin. Slightly soluble to insoluble in benzene, in ether, and in petroleum ether. *NF category:* Alkalizing agent; emulsifying and/or solubilizing agent.

Diethylcarbamazine Citrate: White, crystalline powder. Melts at about 136°, with decomposition. Is odorless or has a slight odor; is slightly hygroscopic. Very soluble in water; sparingly soluble in alcohol; practically insoluble in acetone, in chloroform, and in ether.

Diethylene Glycol Monoethyl Ether: Clear, colorless liquid. Is hygroscopic. Miscible with water, with acetone, and with alcohol; partially miscible with vegetable oils; immiscible with mineral oils. Specific gravity about 0.991. *NF category:* Ointment base; solvent.

Diethylene Glycol Stearates: White or almost white, waxy solid. Soluble in acetone and in hot alcohol; practically insoluble in water. *NF category:* Emulsifying and/or solubilizing agent.

Diethyl Phthalate: Colorless, practically odorless, oily liquid. Insoluble in water. Miscible with alcohol, with ether, and with other usual organic solvents. *NF category:* Plasticizer.

Diethylpropion Hydrochloride: White to off-white, fine crystalline powder. Is odorless, or has a slight characteristic odor. It melts at about 175°, with decomposition. Freely soluble in water, in chloroform, and in alcohol; practically insoluble in ether.

Add the following:

▲ **Diethyl Sebacate:** A colorless to slightly yellow liquid. Miscible with alcohol, with ether, with other organic solvents, and with most fixed oils; insoluble or practically insoluble in water. *NF category:* Flavors and perfumes. ▲ *NF31*

Diethylstilbestrol: White, odorless, crystalline powder. Soluble in alcohol, in chloroform, in ether, in fatty oils, and in dilute alkali hydroxides; practically insoluble in water.

Diethyltoluamide: Colorless liquid, having a faint, pleasant odor. Boils at about 111° under a pressure of 1 mm of mercury. Practically insoluble in water and in glycerin. Miscible with alcohol, with isopropyl alcohol, with ether, with chloroform, and with carbon disulfide.

Diflorasone Diacetate: White to pale yellow, crystalline powder. Soluble in methanol and in acetone; sparingly soluble in ethyl acetate; slightly soluble in toluene; very slightly soluble in ether; insoluble in water.

Diflunisal: White to off-white, practically odorless powder. Freely soluble in alcohol and in methanol; soluble in acetone and in ethyl acetate; slightly soluble in chloroform, in carbon tetrachloride, and in methylene chloride; insoluble in hexane and in water.

Digitoxin: White or pale buff, odorless, microcrystalline powder. Sparingly soluble in chloroform; slightly soluble in alcohol; very slightly soluble in ether; practically insoluble in water.

Digoxin: Clear to white, odorless crystals or white, odorless crystalline powder. Freely soluble in pyridine; slightly soluble in diluted alcohol and in chloroform; practically insoluble in water and in ether.

Dihydroergotamine Mesylate: White to slightly yellowish powder, or off-white to faintly red powder, having a faint odor. Soluble in alcohol; slightly soluble in water and in chloroform.

Dihydrostreptomycin Sulfate: White or almost white, amorphous or crystalline powder. Amorphous form is hygroscopic. Freely soluble in water; practically insoluble in acetone, in chloroform, and in methanol.

Dihydroxycholesterol: Colorless or white, odorless crystals, or white, odorless, crystalline powder. Freely soluble in ether and in chloroform; soluble in alcohol; sparingly soluble in vegetable oils; practically insoluble in water.

Dihydroxyacetone: White to off-white crystalline powder. The monomeric form is freely soluble in water, in alcohol, and in ether. The dimeric form is freely soluble in water; soluble in alcohol; and sparingly soluble in ether.

Dihydroxyaluminum Aminoacetate: White, odorless powder having a faintly sweet taste. Soluble in dilute mineral acids and in solutions of fixed alkalies; insoluble in water and in organic solvents.

Dihydroxyaluminum Aminoacetate Magma: White, viscous suspension, from which small amounts of water may separate on standing.

Dihydroxyaluminum Sodium Carbonate: Fine, white, odorless powder. Soluble in dilute mineral acids with the evolution of carbon dioxide; practically insoluble in water and in organic solvents.

Diloxanide Furoate: White or almost white, crystalline powder. Freely soluble in chloroform; slightly soluble in alcohol and in ether; very slightly soluble in water.

Diltiazem Hydrochloride: White, odorless, crystalline powder or small crystals. Freely soluble in chloroform, in formic acid, in methanol, and in water; sparingly soluble in dehydrated alcohol; insoluble in ether. Melts at about 210°, with decomposition.

Dimenhydrinate: White, crystalline, odorless powder. Freely soluble in alcohol and in chloroform; sparingly soluble in ether; slightly soluble in water.

Dimercaprol: Colorless or practically colorless liquid, having a disagreeable, mercaptan-like odor. Soluble in water, in alcohol, in benzyl benzoate, and in methanol.

Dimercaprol Injection: Yellow, viscous solution having a pungent, disagreeable odor. Specific gravity is about 0.978.

Dimethicone: A clear, colorless, and odorless liquid. Soluble in chlorinated hydrocarbons, in benzene, in toluene, in xylene, in *n*-hexane, in petroleum spirits, in ether, and in amyl acetate; very slightly soluble in isopropyl alcohol; insoluble in water, in methanol, in alcohol, and in acetone. *NF* category: Antifoaming agent; water repelling agent.

Dimethyl Sulfoxide: Clear, colorless, odorless, hygroscopic liquid. Melts at about 18.4°. Boils at about 189°. Soluble in water; practically insoluble in acetone, in alcohol, in benzene, in chloroform, and in ether.

Dinoprostone: White to off-white, crystalline powder. Freely soluble in acetone, in alcohol, in ether, in ethyl acetate, in isopropyl alcohol, in methanol, and in methylene chloride; soluble in toluene and in diisopropyl ether; practically insoluble in hexanes.

Dinoprost Tromethamine: White to off-white, crystalline powder. Very soluble in water; freely soluble in dimethylformamide; soluble in methanol; slightly soluble in chloroform.

Dioxybenzone: Yellow powder. Freely soluble in alcohol and in toluene; practically insoluble in water.

Diphenhydramine Hydrochloride: White, odorless, crystalline powder. Slowly darkens on exposure to light. Its solutions are practically neutral to litmus. Freely soluble in water, in alcohol, and in chloroform; sparingly soluble in acetone; very slightly soluble in benzene and in ether.

Diphenoxylate Hydrochloride: White, odorless, crystalline powder. Its saturated solution has a pH of about 3.3. Freely soluble in chloroform; soluble in methanol; sparingly soluble in alcohol and in acetone; slightly soluble in water and in isopropanol; practically insoluble in ether and in solvent hexane.

Diphtheria and Tetanus Toxoids Adsorbed: Turbid, and white, slightly gray, or slightly pink suspension, free from evident clumps after shaking.

Dipivefrin Hydrochloride: White, crystalline powder or small crystals, having a faint odor. Very soluble in water.

Dipyridamole: Intensely yellow, crystalline powder or needles. Very soluble in methanol, in alcohol, and in chloroform; slightly soluble in water; very slightly soluble in acetone and in ethyl acetate.

Dirithromycin: White or practically white powder. Very soluble in methanol and in methylene chloride; very slightly soluble in water.

Disopyramide Phosphate: White or practically white, odorless powder. Melts at about 205°, with decomposition.

Freely soluble in water; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

Disulfiram: White to off-white, odorless, crystalline powder. Soluble in acetone, in alcohol, in carbon disulfide, and in chloroform; very slightly soluble in water.

Divalproex Sodium: White to off-white powder. Very soluble in chloroform; freely soluble in methanol and in ethyl ether; soluble in acetone; practically insoluble in acetonitrile.

Dobutamine Hydrochloride: White to practically white, crystalline powder. Soluble in alcohol and in pyridine; sparingly soluble in water and in methanol.

Docetaxel: White or almost white, crystalline powder. Freely soluble in acetone; soluble in methanol; practically insoluble in water.

Docosate Calcium: White, amorphous solid, having the characteristic odor of octyl alcohol. It is free of the odor of other solvents. Very soluble in alcohol, in polyethylene glycol 400, and in corn oil; very slightly soluble in water.

Docosate Potassium: White, amorphous solid, having a characteristic odor suggestive of octyl alcohol. Very soluble in solvent hexane; soluble in alcohol and in glycerin; sparingly soluble in water.

Docosate Sodium: White, wax-like, plastic solid, having a characteristic odor suggestive of octyl alcohol, but no odor of other solvents. Very soluble in solvent hexane; freely soluble in alcohol and in glycerin; sparingly soluble in water. *NF* category: Wetting and/or solubilizing agent.

Dofetilide: White to off-white powder. Soluble in 0.1 N sodium hydroxide, in acetone, and in 0.1 N hydrochloric acid; very slightly soluble in water and in isopropyl alcohol.

Dolasetron Mesylate: White to off-white powder. Freely soluble in water and in propylene glycol; slightly soluble in alcohol and in saline TS.

Donepezil Hydrochloride: White crystalline powder. Freely soluble in chloroform; soluble in water and glacial acetic acid; slightly soluble in alcohol and acetonitrile; practically insoluble in ethyl acetate and *n*-hexane.

Dopamine Hydrochloride: White to off-white, crystalline powder. May have a slight odor of hydrochloric acid. Melts at about 240°, with decomposition. Freely soluble in water and in aqueous solutions of alkali hydroxides; soluble in methanol; insoluble in ether and in chloroform.

Dorzolamide Hydrochloride: White to off-white, crystalline powder. Soluble in water.

Doxapram Hydrochloride: White to off-white, odorless, crystalline powder. Melts at about 220°. Soluble in water and in chloroform; sparingly soluble in alcohol; practically insoluble in ether.

Doxazosin Mesylate: White to tan-colored powder. Freely soluble in formic acid; very slightly soluble in methanol and in water.

Doxorubicin Hydrochloride: Red-orange, hygroscopic, crystalline or amorphous powder. Soluble in water, in isotonic sodium chloride solution, and in methanol; practically insoluble in chloroform, in ether, and in other organic solvents.

Doxycycline: Yellow, crystalline powder. Freely soluble in dilute acid and in alkali hydroxide solutions; very slightly soluble in alcohol and in water; practically insoluble in chloroform and in ether.

Doxycycline Hyclate: Yellow, crystalline powder. Soluble in water and in solutions of alkali hydroxides and carbonates; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

Doxylamine Succinate: White or creamy white powder, having a characteristic odor. Very soluble in water and in alcohol; freely soluble in chloroform; very slightly soluble in ether and in benzene.

Dronabinol: Light yellow resinous oil that is sticky at room temperature and hardens upon refrigeration. Insoluble in water.

Droperidol: White to light tan, amorphous or microcrystalline powder. Freely soluble in chloroform; slightly soluble in alcohol and in ether; practically insoluble in water. Melts at about 145°.

Drospirenone: White to off-white powder. Freely soluble in methylene chloride; soluble in acetone and in methanol; sparingly soluble in ethyl acetate and in alcohol; practically insoluble in hexane and in water.

Duloxetine Hydrochloride: White to brownish-white solid. Slightly soluble in water.

Absorbable Dusting Powder: White, odorless powder.

Dyclonine Hydrochloride: White crystals or white crystalline powder, which may have a slight odor. Exhibits local anesthetic properties when placed upon the tongue. Soluble in water, in acetone, in alcohol, and in chloroform.

Dydrogesterone: White to pale yellow, crystalline powder. Sparingly soluble in alcohol; practically insoluble in water.

Dyphylline: White, odorless, extremely bitter, amorphous or crystalline solid. Freely soluble in water; sparingly soluble in alcohol and in chloroform; practically insoluble in ether.

Ecamsule Solution: Clear yellow liquid.

Echothiophate Iodide: White, crystalline, hygroscopic solid having a slight mercaptan-like odor. Its solutions have a pH of about 4. Freely soluble in water and in methanol; soluble in dehydrated alcohol; practically insoluble in other organic solvents.

Echothiophate Iodide for Ophthalmic Solution: White, amorphous powder.

Econazole Nitrate: White or practically white, crystalline powder, having not more than a slight odor. Soluble in methanol; sparingly soluble in chloroform; slightly soluble in alcohol; very slightly soluble in water and in ether.

Edetate Calcium Disodium: White, crystalline granules or white, crystalline powder. Is odorless, is slightly hygroscopic, and has a faint, saline taste. Is stable in air. Freely soluble in water. *NF category:* Chelating agent; complexing agent.

Edetate Disodium: White, crystalline powder. Soluble in water. *NF category:* Chelating agent; complexing agent.

Edetic Acid: White, crystalline powder. Melts above 220°, with decomposition. Soluble in solutions of alkali hydroxides; very slightly soluble in water. *NF category:* Chelating agent; complexing agent.

Edrophonium Chloride: White, odorless, crystalline powder. Its solution (1 in 10) is practically colorless. Very soluble in water; freely soluble in alcohol; insoluble in chloroform and in ether.

Efavirenz: White to slightly pink crystalline powder. Soluble in methanol; practically insoluble in water.

Emedastine Fumarate: White to faintly yellow, crystalline powder. Soluble in water.

Emetine Hydrochloride: White or very slightly yellowish, odorless, crystalline powder. Is affected by light. Freely soluble in water and in alcohol.

Enalapril Maleate: Off-white, crystalline powder. Melts at about 144°. Freely soluble in methanol and in dimethylformamide; soluble in alcohol; sparingly soluble in water; slightly soluble in semipolar organic solvents; practically insoluble in nonpolar organic solvents.

Enalaprilat: White to nearly white, hygroscopic, crystalline powder. Sparingly soluble in methanol and in dimethylformamide; slightly soluble in water and in isopropyl alcohol; very slightly soluble in acetone, in alcohol, and in hexane; practically insoluble in acetonitrile and in chloroform.

Enflurane: Clear, colorless, stable, volatile liquid, having a mild, sweet odor. Is nonflammable. Slightly soluble in water. Miscible with organic solvents, with fats, and with oils.

Enrofloxacin: Pale yellow to light yellow crystalline powder. Very slightly soluble in water at pH 7.

Entacapone: Greenish yellow to yellow powder. Sparingly soluble in acetone and in methanol; slightly soluble in ethanol, chloroform, isopropanol, and ether; very slightly soluble in toluene; practically insoluble in water.

Ephedrine: Unctuous, practically colorless solid or white crystals or granules. Gradually decomposes on exposure to light. Melts between 33° and 40°, the variability in the melting point being the result of differences in the moisture content, anhydrous Ephedrine having a lower melting point than the hemihydrate of Ephedrine. Its solutions are alkaline to litmus. Soluble in water, in alcohol, in chloroform, and in ether; sparingly and slowly soluble in mineral oil, the solution becoming turbid if the Ephedrine contains more than about 1% of water.

Ephedrine Hydrochloride: Fine, white, odorless crystals or powder. Is affected by light. Freely soluble in water; soluble in alcohol; insoluble in ether.

Ephedrine Sulfate: Fine, white, odorless crystals or powder. Darkens on exposure to light. Freely soluble in water; sparingly soluble in alcohol.

Ephedrine Sulfate Nasal Solution: Clear, colorless solution. Is neutral or slightly acid to litmus.

Epinephrine: White to practically white, odorless, microcrystalline powder or granules, gradually darkening on exposure to light and air. With acids, it forms salts that are readily soluble in water, and the base may be recovered by the addition of ammonia water or alkali carbonates. Its solutions are alkaline to litmus. Very slightly soluble in water and in alcohol; insoluble in ether, in chloroform, and in fixed and volatile oils.

Epinephrine Injection: Practically colorless, slightly acid liquid. Gradually turns dark on exposure to light and air.

Epinephrine Inhalation Solution: Practically colorless, slightly acid liquid. Gradually turns dark on exposure to light and air.

Epinephrine Nasal Solution: Nearly colorless, slightly acid liquid. Gradually turns dark on exposure to light and air.

Epinephrine Ophthalmic Solution: Colorless to faint yellow solution. Gradually turns dark on exposure to light and air.

Epinephrine Bitartrate: White, or grayish-white or light brownish-gray, odorless, crystalline powder. Slowly darkens on exposure to air and light. Its solutions are acid to litmus, having a pH of about 3.5. Freely soluble in water; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

Epinephrine Bitartrate for Ophthalmic Solution: White to off-white solid.

Epinephryl Borate Ophthalmic Solution: Clear, pale yellow liquid, gradually darkening on exposure to light and air.

Epirubicin Hydrochloride: Orange-red powder. Soluble in water and in methanol; slightly soluble in anhydrous ethanol; practically insoluble in acetone.

Eprinomectin: White to off-white powder. Insoluble in cold water.

Ergocalciferol: White, odorless crystals. Is affected by air and by light. Soluble in alcohol, in chloroform, in ether, and in fatty oils; insoluble in water.

Ergocalciferol Oral Solution: Clear liquid having the characteristics of the solvent used in preparing the Solution.

Ergoloid Mesylates: White to off-white, microcrystalline or amorphous, practically odorless powder. Soluble in meth-

anol and in alcohol; sparingly soluble in acetone; slightly soluble in water.

Ergonovine Maleate: White to grayish-white or faintly yellow, odorless, microcrystalline powder. Darkens with age and on exposure to light. Sparingly soluble in water; slightly soluble in alcohol; insoluble in ether and in chloroform.

Ergotamine Tartrate: Colorless crystals or white to yellowish-white, crystalline powder. Is odorless. Melts at about 180°, with decomposition. One g dissolves in about 3200 mL of water; in the presence of a slight excess of tartaric acid 1 g dissolves in about 500 mL of water. Slightly soluble in alcohol.

Erythorbic Acid: White or slightly yellow crystals or powder. It gradually darkens when exposed to light. In the dry state, it is reasonably stable in air, but in solution, it rapidly deteriorates in the presence of air. It melts between 164° and 171° with decomposition. One g is soluble in about 2.5 mL of water and in about 20 mL of alcohol. Slightly soluble in glycerin. *NF category:* Antimicrobial preservative; antioxidant.

Erythritol: White or almost white, crystalline powder or free-flowing granules. It is stable to heat and is nonhygroscopic. Freely soluble in water; very slightly soluble in alcohol. *NF category:* Humectant; sweetening agent.

Erythromycin: White or slightly yellow, crystalline powder. Is odorless or practically odorless. Soluble in alcohol, in chloroform, and in ether; slightly soluble in water.

Erythromycin Estolate: White, crystalline powder. Is odorless or practically odorless, and is practically tasteless. Soluble in alcohol, in acetone, and in chloroform; practically insoluble in water.

Erythromycin Ethylsuccinate: White or slightly yellow crystalline powder. Is odorless or practically odorless, and is practically tasteless. Freely soluble in alcohol, in chloroform, and in polyethylene glycol 400; very slightly soluble in water.

Erythromycin Gluceptate: Colorless to white crystals. Slightly hygroscopic. Freely soluble in water, in alcohol, in methanol, in dioxane, and in propylene glycol; slightly soluble in acetone and in chloroform; practically insoluble in ether, in carbon tetrachloride, in benzene, and in toluene.

Erythromycin Lactobionate for Injection: White or slightly yellow crystals or powder, having a faint odor. Its solution (1 in 20) is neutral or slightly alkaline. Freely soluble in water, in alcohol, and in methanol; slightly soluble in acetone and in chloroform; practically insoluble in ether.

Erythromycin Stearate: White or slightly yellow crystals or powder. Is odorless or may have a slight, earthy odor, and has a slightly bitter taste. Soluble in alcohol, in chloroform, in methanol, and in ether; practically insoluble in water.

Esmolol Hydrochloride: White to off-white crystalline powder. Very soluble in water; freely soluble in alcohol.

Escitalopram Oxalate: Fine, white to slightly yellow powder. Freely soluble in methanol and in dimethyl sulfoxide; sparingly soluble in water and in alcohol; very slightly soluble in ethyl acetate and in isopropyl alcohol; insoluble in heptane.

Esomeprazole Magnesium: White to slightly colored powder. Soluble in methanol; slightly soluble in water; practically insoluble in heptane.

Estazolam: White to pale yellowish-white crystal. Soluble in methanol and in acetic anhydride; sparingly soluble in ethanol; practically insoluble in water and in ether.

Estradiol: White or creamy white, small crystals or crystalline powder. Is odorless, and is stable in air. Is hygroscopic. Soluble in alcohol, in acetone, in dioxane, in chloroform, and in solutions of fixed alkali hydroxides; sparingly soluble in vegetable oils; practically insoluble in water.

Estradiol Benzoate: White to off-white, crystalline powder. Soluble in alcohol and in acetone; slightly soluble in diethyl ether; insoluble in water.

Estradiol Cypionate: White to practically white, crystalline powder. Is odorless or has a slight odor. Soluble in alcohol, in acetone, in chloroform, and in dioxane; sparingly soluble in vegetable oils; insoluble in water.

Estradiol Valerate: White, crystalline powder. Is usually odorless but may have a faint, fatty odor. Soluble in castor oil, in methanol, in benzyl benzoate, and in dioxane; sparingly soluble in sesame oil and in peanut oil; practically insoluble in water.

Estriol: White to practically white, odorless, crystalline powder. Melts at about 280°. Soluble in acetone, in chloroform, in dioxane, in ether, and in vegetable oils; sparingly soluble in alcohol; insoluble in water.

Conjugated Estrogens: Conjugated Estrogens obtained from natural sources is a buff-colored, amorphous powder, odorless or having a slight, characteristic odor. The synthetic form is a white to light buff, crystalline or amorphous powder, odorless or having a slight odor.

Synthetic Conjugated Estrogens: A white to light buff, crystalline or amorphous powder that is odorless or has a slight odor.

Esterified Estrogens: White or buff-colored, amorphous powder, odorless or having a slight, characteristic odor.

Estrone: Small, white crystals or white to creamy white, crystalline powder. Is odorless, and is stable in air. Melts at about 260°. Soluble in alcohol, in acetone, in dioxane, and in vegetable oils; slightly soluble in solutions of fixed alkali hydroxides; practically insoluble in water.

Estopipate: White to yellowish-white, fine, crystalline powder. Is odorless, or may have a slight odor. Melts at about 190° to a light brown, viscous liquid, which solidifies on further heating and finally melts at about 245°, with decomposition. Soluble in warm water; very slightly soluble in water, in alcohol, in chloroform, and in ether.

Ethacrynic Acid: White or practically white, odorless or practically odorless, crystalline powder. Freely soluble in alcohol, in chloroform, and in ether; very slightly soluble in water.

Ethambutol Hydrochloride: White, crystalline powder. Freely soluble in water; soluble in alcohol and in methanol; slightly soluble in ether and in chloroform.

Ethchlorvynol: Colorless to yellow, slightly viscous liquid, having a characteristic pungent odor. Darkens on exposure to light and air. Immiscible with water; miscible with most organic solvents.

Ether: Colorless, mobile, volatile liquid, having a characteristic sweet, pungent odor. Is slowly oxidized by the action of air and light, with the formation of peroxides. It boils at about 35°. Soluble in water and in hydrochloric acid. Miscible with alcohol, with benzene, with chloroform, with solvent hexane, with methylene chloride, and with fixed and volatile oils.

Ethinyl Estradiol: White to creamy white, odorless, crystalline powder. Soluble in alcohol, in chloroform, in ether, in vegetable oils, and in solutions of fixed alkali hydroxides; insoluble in water.

Ethiodized Oil Injection: Straw-colored to amber-colored, oily liquid. It may possess an alliaceous odor. Soluble in acetone, in chloroform, in ether, and in solvent hexane; insoluble in water.

Ethionamide: Bright yellow powder, having a faint to moderate sulfide-like odor. Soluble in methanol; sparingly soluble in alcohol and in propylene glycol; slightly soluble in water, in chloroform, and in ether.

Ethopabate: White to pinkish-white, odorless or practically odorless powder. Soluble in acetonitrile, in acetone, in dehydrated alcohol, and in methanol; sparingly soluble in isopropyl alcohol, in dioxane, in ethyl acetate, and in meth-

ylene chloride; slightly soluble in ether; very slightly soluble in water.

Ethosuximide: White to off-white, crystalline powder or waxy solid, having a characteristic odor. Freely soluble in water and in chloroform; very soluble in alcohol and in ether; very slightly soluble in solvent hexane.

Ethotoin: White, crystalline powder. Freely soluble in dehydrated alcohol and in chloroform; soluble in ether; insoluble in water.

Ethyl Acetate: Transparent, colorless liquid, having a fragrant, refreshing, slightly acetous odor, and a peculiar, acetous, burning taste. Soluble in water. Miscible with alcohol, with ether, with fixed oils, and with volatile oils. *NF category:* Flavors and perfumes; solvent.

Ethyl Acrylate and Methyl Methacrylate Copolymer Dispersion: Milky-white liquid of low viscosity with a faint, characteristic odor. It is miscible with water in any proportion; the milky-white appearance is retained. A clear or slightly opalescent, viscous solution is obtained on mixing one part with five parts of acetone, alcohol, or isopropyl alcohol; the polymer substance first precipitates, but then dissolves in the excess organic solvent. When mixed with 1 N sodium hydroxide in a ratio of 1:2, the dispersion does not dissolve; the milky-white appearance is retained. *NF category:* Coating agent; polymer membrane; tablet binder.

Ethyl Chloride: Colorless, mobile, very volatile liquid at low temperatures or under pressure, having a characteristic, ethereal odor. It boils between 12° and 13°, and its specific gravity at 0° is about 0.921. When liberated at room temperature from its sealed container, it vaporizes immediately. It burns with a smoky, greenish flame, producing hydrogen chloride. Freely soluble in alcohol and in ether; slightly soluble in water.

Ethyl Oleate: Mobile, practically colorless liquid, having an agreeable taste. Insoluble in water. Miscible with vegetable oils, with mineral oil, with alcohol, and with most organic solvents. *NF category:* Vehicle (oleaginous).

Ethyl Maltol: White, crystalline powder having a cotton-candy odor and a sweet, fruitlike flavor in dilute solution. One g dissolves in about 55 mL of water, 10 mL of alcohol, 17 mL of propylene glycol, and 5 mL of chloroform. It melts at about 90°. *NF category:* Vehicle (flavored and/or sweetened).

Ethyl Vanillin: Fine, white or slightly yellowish crystals. Its taste and odor are similar to the taste and odor of vanillin. Is affected by light. Its solutions are acid to litmus. Freely soluble in alcohol, in chloroform, in ether, and in solutions of alkali hydroxides; sparingly soluble in water at 50°. *NF category:* Flavors and perfumes.

Ethylcellulose: Free-flowing, white to light tan powder. It forms films that have a refractive index of about 1.47. Its aqueous suspensions are neutral to litmus. Ethylcellulose containing less than 46.5% of ethoxy groups is freely soluble in tetrahydrofuran, in methyl acetate, in chloroform, and in mixtures of aromatic hydrocarbons with alcohol; Ethylcellulose containing not less than 46.5% of ethoxy groups is freely soluble in alcohol, in methanol, in toluene, in chloroform, and in ethyl acetate; insoluble in water, in glycerin, and in propylene glycol. *NF category:* Coating agent; tablet binder.

Ethylcellulose Dispersion Type B: Off-white and slightly viscous liquid. Soluble in alcohol, in methyl alcohol, in toluene, in chloroform, and in ethyl acetate; insoluble in water, in glycerin, and in propylene glycol. *NF category:* Coating agent; film-forming agent.

Ethylenediamine: Clear, colorless or only slightly yellow liquid, having an ammonia-like odor and a strong alkaline reaction. Miscible with water and with alcohol.

Ethylene Glycol Stearates: White or almost white, waxy solid. Soluble in acetone and in hot alcohol; practically insoluble in water. *NF category:* Emulsifying and/or solubilizing agent.

Ethylene Glycol and Vinyl Alcohol Graft Copolymer:

White or slightly yellowish powder. Very soluble in water; practically insoluble in anhydrous alcohol, and in acetone. It dissolves in dilute acids and dilute solutions of alkali hydroxides. *NF category:* Coating agent; tablet binder.

Ethylparaben: Small, colorless crystals or white powder. Freely soluble in acetone, in alcohol, in ether, and in propylene glycol; slightly soluble in water and in glycerin. *NF category:* Antimicrobial preservative.

Ethynodiol Diacetate: White, odorless, crystalline powder. Is stable in air. Very soluble in chloroform; freely soluble in ether; soluble in alcohol; sparingly soluble in fixed oils; insoluble in water.

Etidronate Disodium: White powder, which may contain lumps. Freely soluble in water; practically insoluble in alcohol.

Etomidate: White or almost white powder. Freely soluble in alcohol and in methylene chloride; very slightly soluble in water.

Etoposide: Fine, white to off-white, crystalline powder. Sparingly soluble in methanol; slightly soluble in alcohol, in chloroform, in ethyl acetate, and in methylene chloride; very slightly soluble in water.

Eugenol: Colorless or pale yellow liquid, having a strongly aromatic odor of clove and a pungent, spicy taste. Upon exposure to air, it darkens and thickens. Is optically inactive. Slightly soluble in water. Miscible with alcohol, with chloroform, with ether, and with fixed oils.

Famotidine: White to pale yellowish-white, crystalline powder. Is sensitive to light. Freely soluble in dimethylformamide and in glacial acetic acid; slightly soluble in methanol; very slightly soluble in water; practically insoluble in acetone, in alcohol, in chloroform, in ether, and in ethyl acetate.

Hard Fat: White mass; almost odorless and free from rancid odor; greasy to the touch. On warming, melts to give a colorless or slightly yellowish liquid. When the molten material is shaken with an equal quantity of hot water, a white emulsion is formed. Freely soluble in ether; slightly soluble in alcohol; practically insoluble in water. *NF category:* Stiffening agent; suppository base.

Felbamate: White to off-white powder. Freely soluble in dimethyl sulfoxide; sparingly soluble in methanol; slightly soluble in acetonitrile; very slightly soluble in water.

Felodipine: Light yellow to yellow, crystalline powder. Freely soluble in acetone and in methanol; very slightly soluble in heptane; insoluble in water.

Fenbendazole: White to off-white powder. Sparingly soluble in dimethylformamide; very slightly soluble in methanol; practically insoluble in water.

Fenofibrate: White or almost white, crystalline powder. Very soluble in methylene chloride; slightly soluble in alcohol; practically insoluble in water.

Fenoldopam Mesylate: White to off-white powder. Soluble in water.

Fenoprofen Calcium: White, crystalline powder. Slightly soluble in *n*-hexanol, in methanol, and in water; practically insoluble in chloroform.

Fentanyl Citrate: White, crystalline powder or white, glistening crystals. Melts at about 150°, with decomposition. Soluble in methanol; sparingly soluble in water; slightly soluble in chloroform.

Ferric Oxide: Powder exhibiting two basic colors (red and yellow), or other shades produced on blending the basic colors. Insoluble in water and in organic solvents; dissolves in hydrochloric acid upon warming, a small amount of insoluble residue usually remaining. *NF category:* Color.

Ferric Subsulfate Solution: Reddish-brown liquid, odorless or nearly so. Acid to litmus, and is affected by light. Specific gravity is about 1.548.

Ferric Sulfate: Grayish-white or yellowish powder or fawn-colored pearls. Hygroscopic. Slightly soluble in water and in ethanol (96%); practically insoluble in acetone and in ethyl acetate. Hydrolyzes slowly in aqueous solution.

Ferrosoferric Oxide: Black powder. Dissolves in hydrochloric acid upon warming, a small amount of insoluble residue usually remaining; insoluble in water and in organic solvents. *NF category:* Color.

Ferrous Fumarate: Reddish-orange to red-brown, odorless powder. May contain soft lumps that produce a yellow streak when crushed. Slightly soluble in water; very slightly soluble in alcohol. Its solubility in dilute hydrochloric acid is limited by the separation of fumaric acid.

Ferrous Gluconate: Yellowish-gray or pale greenish-yellow, fine powder or granules, having a slight odor resembling that of burned sugar. Its solution (1 in 20) is acid to litmus. Soluble in water, with slight heating; practically insoluble in alcohol.

Ferrous Sulfate: Pale, bluish-green crystals or granules. Is odorless and is efflorescent in dry air. Oxidizes readily in moist air to form brownish yellow basic ferric sulfate. Its solution (1 in 10) is acid to litmus, having a pH of about 3.7. Very soluble in boiling water; freely soluble in water; insoluble in alcohol.

Dried Ferrous Sulfate: Grayish-white to buff-colored powder, consisting primarily of $\text{FeSO}_4 \cdot \text{H}_2\text{O}$ with varying amounts of $\text{FeSO}_4 \cdot 4\text{H}_2\text{O}$. Slowly soluble in water; insoluble in alcohol.

Ferumoxides Injection: Black to reddish-brown, aqueous colloid. It is stable for 24 hours after dilution.

Add the following:

▲ **Fexofenadine Hydrochloride:** White to off-white powder. Freely soluble in methanol; slightly soluble in water; very slightly soluble in acetone. ▲ *USP36*

Finasteride: White to off-white, crystalline solid. Melts at about 257°. Freely soluble in chloroform and in alcohol; very slightly soluble in water.

Fish Oil Containing Omega-3 Acids: Pale yellow liquid. Very soluble in acetone and in heptane; slightly soluble in anhydrous alcohol; practically insoluble in water.

Flavoxate Hydrochloride: White or almost white, crystalline powder. Slightly soluble in alcohol, in water, and in methylene chloride.

Flecainide Acetate: White to slightly off-white, crystalline powder. Freely soluble in alcohol; soluble in water. pK_a is 9.3.

Fluconazole: White or almost white, crystalline powder. Freely soluble in methanol; soluble in alcohol and in acetone; sparingly soluble in isopropanol and in chloroform; slightly soluble in water; very slightly soluble in toluene.

Flucytosine: White to off-white, crystalline powder. Is odorless or has a slight odor. Sparingly soluble in water; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

Fludarabine Phosphate: White to off-white, crystalline, hygroscopic powder. Freely soluble in dimethylformamide; slightly soluble in water and in 0.1 M hydrochloric acid; practically insoluble in ethanol.

Fludrocortisone Acetate: White to pale yellow crystals or crystalline powder. Is odorless or practically odorless. Is hygroscopic. Sparingly soluble in alcohol and in chloroform; slightly soluble in ether; insoluble in water.

Flumazenil: White to off-white powder. Slightly soluble in acidic aqueous solutions; practically insoluble in water.

Flumethasone Pivalate: White to off-white, crystalline powder. Slightly soluble in methanol; very slightly soluble in chloroform and in methylene chloride; insoluble in water.

Flunisolide: White to creamy-white, crystalline powder. Melts at about 245°, with decomposition. Soluble in acetone; sparingly soluble in chloroform; slightly soluble in methanol; practically insoluble in water.

Flunixin Meglumine: White to off-white crystalline powder. Soluble in water, in alcohol, and in methanol; practically insoluble in ethyl acetate.

Fluocinolone Acetonide: White or practically white, odorless, crystalline powder. Is stable in air. Melts at about 270°, with decomposition. Soluble in methanol; slightly soluble in ether and in chloroform; insoluble in water.

Fluocinonide: White to cream-colored, crystalline powder, having not more than a slight odor. Sparingly soluble in acetone and in chloroform; slightly soluble in alcohol, in methanol, and in dioxane; very slightly soluble in ether; practically insoluble in water.

Fluorescein: Yellowish-red to red, odorless powder. Soluble in dilute alkali hydroxides; insoluble in water.

Fluorescein Sodium: Orange-red, hygroscopic, odorless powder. Freely soluble in water; sparingly soluble in alcohol.

Fluorescein Sodium Ophthalmic Strip: Each Strip is a dry, white piece of paper, one end of which is rounded and is uniformly orange-red in color because of the fluorescein sodium impregnated in the paper.

Fluorometholone: White to yellowish-white, odorless, crystalline powder. Melts at about 280°, with some decomposition. Slightly soluble in alcohol; very slightly soluble in chloroform and in ether; practically insoluble in water.

Fluorouracil: White to practically white, practically odorless, crystalline powder. Decomposes at about 282°. Sparingly soluble in water; slightly soluble in alcohol; practically insoluble in chloroform and in ether.

Fluoxetine Hydrochloride: White to off-white crystalline powder. Freely soluble in alcohol and in methanol; sparingly soluble in water and in dichloromethane; practically insoluble in ether.

Fluoxymesterone: White or practically white, odorless, crystalline powder. Melts at about 240°, with some decomposition. Sparingly soluble in alcohol; slightly soluble in chloroform; practically insoluble in water.

Fluphenazine Enanthate: Pale yellow to yellow-orange, clear to slightly turbid, viscous liquid, having a characteristic odor. Is unstable in strong light, but stable to air at room temperature. Freely soluble in alcohol, in chloroform, and in ether; insoluble in water.

Fluphenazine Hydrochloride: White or nearly white, odorless, crystalline powder. Melts, within a range of 5°, at a temperature above 225°. Freely soluble in water; slightly soluble in acetone, in alcohol, and in chloroform; practically insoluble in benzene and in ether.

Flurandrenolide: White to off-white, fluffy, crystalline powder. Is odorless. Freely soluble in chloroform; soluble in methanol; sparingly soluble in alcohol; practically insoluble in water and in ether.

Flurazepam Hydrochloride: Off-white to yellow, crystalline powder. Is odorless, or has a slight odor, and its solutions are acid to litmus. Melts at about 212°, with decomposition. Freely soluble in water and in alcohol; slightly soluble in isopropyl alcohol and in chloroform.

Flurbiprofen: White, crystalline powder. Freely soluble in acetone, in dehydrated alcohol, in ether, and in methanol; soluble in acetonitrile; practically insoluble in water. Optically inactive (1 in 50 solution in dehydrated alcohol).

Flutamide: Pale yellow, crystalline powder. Freely soluble in acetone, in ethyl acetate, and in methanol; soluble in chloroform and in ether; practically insoluble in mineral oil, in petroleum ether, and in water.

Fluticasone Propionate (micronized): Fine, white powder.

Fluvastatin Sodium: White to pale yellow, brownish-pale yellow, or reddish-pale yellow, hygroscopic powder. Soluble in alcohol, in methanol, and in water.

Fluvoxamine Maleate: White to off-white, crystalline powder. Freely soluble in alcohol and in chloroform; sparingly soluble in water; and practically insoluble in diethyl ether.

Folic Acid: Yellow, yellow-brownish, or yellowish-orange, odorless, crystalline powder. It readily dissolves in dilute solutions of alkali hydroxides and carbonates. Soluble in hot, 3 N hydrochloric acid, in hot, 2 N sulfuric acid, in hydrochloric acid, and in sulfuric acid, yielding very pale yellow solutions; very slightly soluble in water; insoluble in alcohol, in acetone, in chloroform, and in ether.

Folic Acid Injection: Clear, yellow to orange-yellow, alkaline liquid.

Formaldehyde Solution: Clear, colorless or practically colorless liquid, having a pungent odor. The vapor from it irritates the mucous membrane of the throat and nose. On long standing, especially in the cold, it may become cloudy because of the separation of paraformaldehyde. This cloudiness disappears when the solution is warmed. Miscible with water and with alcohol.

Formoterol Fumarate Dihydrate: White or almost white or slightly yellow powder. Freely soluble in dimethyl sulfoxide and in acetic acid; soluble in methanol; slightly soluble in water and in 2-propanol; practically insoluble in acetonitrile and in diethyl ether.

Foscarnet Sodium: White to almost white, crystalline powder. Soluble in water; practically insoluble in alcohol.

Fosphenytoin Sodium: White to pale yellow solid. Freely soluble in water.

Fructose: Colorless crystals or as a white, crystalline powder. Is odorless, and has a sweet taste. Freely soluble in water; soluble in alcohol and in methanol. *NF category:* Sweetening agent; tablet and/or capsule diluent.

Basic Fuchsin: Dark green powder or greenish glistening crystalline fragments, having a bronze-like luster and not more than a faint odor. Soluble in water, in alcohol, and in amyl alcohol; insoluble in ether.

Fulvestrant: White powder. Freely soluble in alcohol.

Fumaric Acid: White, odorless granules or crystalline powder. Soluble in alcohol; slightly soluble in water and in ether; very slightly soluble in chloroform. *NF category:* Acidifying agent.

Furazolidone: Yellow, odorless, crystalline powder. Is tasteless at first, then a bitter aftertaste develops. Practically insoluble in water, in alcohol, and in carbon tetrachloride.

Furosemide: White to slightly yellow, odorless, crystalline powder. Freely soluble in acetone, in dimethylformamide, and in solutions of alkali hydroxides; soluble in methanol; sparingly soluble in alcohol; slightly soluble in ether; very slightly soluble in chloroform; practically insoluble in water.

Furosemide Injection: Clear, colorless solution.

Gabapentin: White to off-white, crystalline solid. Freely soluble in water and in alkaline and acidic solutions.

Gadodiamide: White, odorless powder. Freely soluble in water and in methanol; soluble in ethyl alcohol; slightly soluble in acetone and in chloroform.

Gadoteridol: White to off-white, crystalline, odorless powder. Freely soluble in water and in methyl alcohol; soluble in isopropyl alcohol. Melts at about 300°.

Gadoversetamide: White, odorless powder. Freely soluble in water.

Galactose: A white, crystalline or finely granulated powder. Soluble in water; very slightly soluble in alcohol. *NF category:* Sweetening agent.

Galantamine Hydrobromide: White to almost white powder. Soluble in 0.1 N sodium hydroxide; sparingly solu-

ble in water; very slightly soluble in alcohol; insoluble in *n*-propanol.

Gallamine Triethiodide: White, odorless, amorphous powder. Is hygroscopic. Very soluble in water; sparingly soluble in alcohol; very slightly soluble in chloroform.

Gamma Cyclodextrin: White or almost white, amorphous or crystalline powder. Freely soluble in water and in propylene glycol; very slightly soluble in alcohol. *NF category:* Sequestering agent; emulsifying and/or solubilizing agent.

Ganciclovir: White to off-white, crystalline powder.

Ganciclovir for Injection: White to off-white powder. Soluble in water.

Petrolatum Gauze: The petrolatum recovered by draining in the *Assay* is a white or faintly yellowish, unctuous mass, transparent in thin layers even after cooling to 0°.

Gelatin: Sheets, flakes, or shreds, or coarse to fine powder. Is faintly yellow or amber in color, the color varying in depth according to the particle size. Has a slight, characteristic bouillon-like odor in solution. Is stable in air when dry, but is subject to microbial decomposition when moist or in solution. Gelatin has any suitable strength that is designated by Bloom Gelometer number (see *Gel Strength of Gelatin* (1081)). Type A Gelatin exhibits an isoelectric point between pH 7 and pH 9, and Type B Gelatin exhibits an isoelectric point between pH 4.7 and pH 5.2. Soluble in hot water, in 6 N acetic acid, and in a hot mixture of glycerin and water; insoluble in cold water, but swells and softens when immersed in it, gradually absorbing from 5 to 10 times its own weight of water, in alcohol, in chloroform, in ether, and in fixed and volatile oils. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; tablet binder.

Absorbable Gelatin Film: Light amber, transparent, pliable film which becomes rubbery when moistened. Insoluble in water.

Absorbable Gelatin Sponge: Light, nearly white, nonelastic, tough, porous, hydrophilic solid. Insoluble in water.

Gellan Gum: Off-white powder. Soluble in hot or in cold deionized water. *NF category:* Suspending and/or viscosity-increasing agent.

Gemcitabine Hydrochloride: White to off-white solid. Soluble in water; slightly soluble in methanol; practically insoluble in alcohol and in polar organic solvents.

Gemfibrozil: White, waxy, crystalline solid. Soluble in alcohol, in methanol, and in chloroform; practically insoluble in water.

Gentamicin Sulfate: White to buff powder. Freely soluble in water; insoluble in alcohol, in acetone, in chloroform, in ether, and in benzene.

Gentamicin Injection: Clear, slightly yellow solution, having a faint odor.

Gentian Violet: Dark green powder or greenish, glistening pieces having a metallic luster, and having not more than a faint odor. Soluble in alcohol, in glycerin, and in chloroform; sparingly soluble in water; insoluble in ether.

Gentian Violet Cream: Dark purple, water-washable cream.

Gentian Violet Topical Solution: Purple liquid, having a slight odor of alcohol. A dilution (1 in 100), viewed downward through 1 cm of depth, is deep purple in color.

Powdered Asian Ginseng Extract: Pale yellow-brown, hygroscopic, powdery or easily pulverizable mass. Soluble in water, forming a slightly cloudy solution.

Glaze, Pharmaceutical: Denatured alcohol solution. *NF category:* Coating agent.

Glimepiride: White to almost white powder. Soluble in dimethylformamide; sparingly soluble in methylene chloride; slightly soluble in methanol; practically insoluble in water.

Glipizide: White to off-white powder. Freely soluble in dimethylformamide; soluble in 0.1 N sodium hydroxide; slightly soluble in methylene chloride.

Immune Globulin: Transparent or slightly opalescent liquid, either colorless or of a brownish color due to denatured hemoglobin. Is practically odorless. May develop a slight, granular deposit during storage.

Rh₀(D) Immune Globulin: Transparent or slightly opalescent liquid. Is practically colorless and odorless. May develop a slight, granular deposit during storage.

Glucagon: Fine, white or faintly colored, crystalline powder. Is practically odorless and tasteless. Soluble in dilute alkali and acid solutions; insoluble in most organic solvents.

Glucagon for Injection: White, odorless powder.

Glucanolate: Fine, white, practically odorless, crystalline powder. Melts at about 153°, with decomposition. Freely soluble in water; sparingly soluble in alcohol; insoluble in ether.

Liquid Glucose: Colorless or yellowish, thick, syrupy liquid. Odorless or nearly odorless, and has a sweet taste. Sparingly soluble in alcohol. Miscible with water. *NF category:* Tablet binder.

L-Glutamic Acid Hydrochloride: A white, crystalline powder. 1 g dissolves in about 3 mL of water. It is almost insoluble in alcohol and in ether. Its solutions are acid to litmus. *NF category:* Flavors and perfumes.

Glutamine: White crystals or crystalline powder. Soluble in water; practically insoluble in alcohol and in ether.

Glutaral Concentrate: Clear, colorless or faintly yellow liquid, having a characteristic, irritating odor.

Glycerin: Clear, colorless, syrupy liquid, having a sweet taste. Has not more than a slight characteristic odor, which is neither harsh nor disagreeable. Is hygroscopic. Its solutions are neutral to litmus. Insoluble in chloroform, in ether, and in fixed and volatile oils. Miscible with water and with alcohol. *NF category:* Humectant; plasticizer; solvent; tonicity agent.

Glyceryl Behenate: Fine powder, having a faint odor. Melts at about 70°. Soluble in chloroform; practically insoluble in water and in alcohol.

Glyceryl Distearate: Hard, waxy mass or powder or white or almost white flakes. Soluble in methylene chloride and in tetrahydrofuran; slightly soluble in hot alcohol; insoluble in water. *NF category:* Emulsifying and/or solubilizing agent.

Glyceryl Monolinoleate: Amber, oily liquids that may be partially solidified at room temperature. Freely soluble in methylene chloride; soluble in tetrahydrofuran; practically insoluble in water. *NF category:* Emulsifying and/or solubilizing agent.

Glyceryl Monooleate: Amber, oily liquids that may be partially solidified at room temperature. Freely soluble in methylene chloride; soluble in tetrahydrofuran; practically insoluble in water. *NF category:* Emulsifying and/or solubilizing agent.

Glyceryl Monostearate: White to yellowish wax-like solid; or white to yellowish wax-like beads, flakes, or powder. Slight, agreeable, fatty odor and taste. Is affected by light. Dissolves in hot organic solvents such as alcohol, minerals or fixed oils, benzene, ether, and acetone. Insoluble in water, but it may be dispersed in hot water with the aid of a small amount of soap or other suitable surface-active agent. *NF category:* Emulsifying and/or solubilizing agent.

Add the following:

▲ **Glyceryl Tristearate:** White, solid, microcrystalline powder. Soluble in hot alcohol, in acetone, and in chloro-

form; very slightly soluble in cold alcohol, in ether, and in petroleum ether; insoluble in water. *NF category:* Tablet and/or capsule lubricant; emulsifying and/or solubilizing agent. ▲ *NF31*

Glycine: White, odorless, crystalline powder, having a sweetish taste. Its solutions are acid to litmus. Freely soluble in water; very slightly soluble in alcohol and in ether.

Glycopyrrolate: White, odorless, crystalline powder. Soluble in water and in alcohol; practically insoluble in chloroform and in ether.

Gonadorelin Acetate: White to slightly yellowish powder. Soluble in water; sparingly soluble in methanol.

Chorionic Gonadotropin: White or practically white, amorphous powder. Freely soluble in water.

Chorionic Gonadotropin for Injection: White or practically white, amorphous solid having the characteristic appearance of substances prepared by freeze-drying.

Gramicidin: White or practically white, odorless, crystalline powder. Soluble in alcohol; insoluble in water.

Granisetron Hydrochloride: White or almost white powder. Freely soluble in water; sparingly soluble in methylene chloride; slightly soluble in methanol.

Green Soap: Soft, unctuous, yellowish-white to brownish or greenish yellow, transparent to translucent mass. Has a slight, characteristic odor, often suggesting the oil from which it was prepared. Its solution (1 in 20) is alkaline to bromothymol blue TS.

Griseofulvin: White to creamy white, odorless powder, in which particles of the order of 4 µm in diameter predominate. Soluble in acetone, in dimethylformamide, and in chloroform; sparingly soluble in alcohol; very slightly soluble in water.

Guaifenesin: White to slightly gray, crystalline powder. May have a slight characteristic odor. Soluble in water, in alcohol, in chloroform, and in propylene glycol; sparingly soluble in glycerin.

Guanabenz Acetate: White or almost white powder having not more than a slight odor. Soluble in alcohol and in propylene glycol; sparingly soluble in water and in 0.1 N hydrochloric acid.

Guanadrel Sulfate: White to off-white, crystalline powder. Melts at about 235°, with decomposition. Soluble in water; sparingly soluble in methanol; slightly soluble in alcohol and in acetone.

Guanethidine Monosulfate: White to off-white, crystalline powder. Very soluble in water; sparingly soluble in alcohol; practically insoluble in chloroform.

Guar Gum: White to yellowish-white, practically odorless powder. Dispersible in hot or cold water, forming a colloidal solution. *NF category:* Suspending and/or viscosity-increasing agent; tablet binder.

Gutta Percha: Lumps or blocks of variable size; externally brown or grayish-brown to grayish-white in color; internally reddish yellow or reddish gray and having a laminated or fibrous appearance. Is flexible but only slightly elastic. Has a slight, characteristic odor and a slight taste. Soluble in chloroform; partly soluble in benzene, in carbon disulfide, and in turpentine oil; insoluble in water.

Halazone: White, crystalline powder, having a characteristic chlorine-like odor. Is affected by light. Melts at about 194°, with decomposition. Soluble in glacial acetic acid; very slightly soluble in water and in chloroform. Dissolves in solutions of alkali hydroxides and carbonates with the formation of a salt.

Halazone Tablets for Solution: Soluble in water.

Halcinonide: White to off-white, odorless, crystalline powder. Soluble in acetone and in chloroform; slightly soluble in alcohol and in ethyl ether; insoluble in water and in hexanes.

Halobetasol Propionate: White to off-white powder. Freely soluble in dichloromethane and in acetone; practically insoluble in water.

Haloperidol: White to faintly yellowish, amorphous or microcrystalline powder. Its saturated solution is neutral to litmus. Soluble in chloroform; sparingly soluble in alcohol; slightly soluble in ether; practically insoluble in water.

Haloperidol Decanoate: A white or almost white powder. Very soluble in alcohol, in methanol, and in methylene chloride; practically insoluble in water.

Halothane: Colorless, mobile, nonflammable, heavy liquid, having a characteristic odor resembling that of chloroform. Its taste is sweet and produces a burning sensation. Slightly soluble in water. Miscible with alcohol, with chloroform, with ether, and with fixed oils.

Helium: Colorless, odorless, tasteless gas, which is not combustible and does not support combustion. Very slightly soluble in water. At 0° and at a pressure of 760 mm of mercury, 1000 mL of the gas weighs about 180 mg.

Heparin Sodium: White or pale-colored, amorphous powder. Is odorless or practically so, and is hygroscopic. Soluble in water.

Hexachlorophene: White to light tan, crystalline powder. Is odorless or has only a slight, phenolic odor. Freely soluble in acetone, in alcohol, and in ether; soluble in chloroform and in dilute solutions of fixed alkali hydroxides; insoluble in water.

Hexachlorophene Liquid Soap: Clear, amber-colored liquid, having a slight, characteristic odor. Its solution (1 in 20) is clear and has an alkaline reaction.

Hexylene Glycol: Clear, colorless, viscous liquid. Absorbs moisture when exposed to moist air. Miscible with water and with many organic solvents, including alcohol, ether, chloroform, acetone, and hexanes. *NF category:* Humectant; solvent.

Histamine Phosphate: Colorless, odorless, long prismatic crystals. Is stable in air but is affected by light. Its solutions are acid to litmus. Freely soluble in water.

Histidine: White, odorless crystals, having a slightly bitter taste. Soluble in water; very slightly soluble in alcohol; insoluble in ether.

Histoplasmin: Clear, red liquid. Miscible with water.

Homatropine Hydrobromide: White crystals, or white, crystalline powder. Slowly darkens on exposure to light. Freely soluble in water; sparingly soluble in alcohol; slightly soluble in chloroform; insoluble in ether. Melts between 214° and 217°, with slight decomposition.

Homatropine Methylbromide: White, odorless powder. Slowly darkens on exposure to light. Melts at about 190°. Very soluble in water; freely soluble in alcohol and in acetone containing about 20% of water; practically insoluble in ether and in acetone.

Hydralazine Hydrochloride: White to off-white, odorless, crystalline powder. Melts at about 275°, with decomposition. Soluble in water; slightly soluble in alcohol; very slightly soluble in ether.

Hydrochloric Acid: Colorless, fuming liquid having a pungent odor. It ceases to fume when it is diluted with 2 volumes of water. Specific gravity is about 1.18. *NF category:* Acidifying agent.

Diluted Hydrochloric Acid: Colorless, odorless liquid. Specific gravity is about 1.05. *NF category:* Acidifying agent.

Hydrochlorothiazide: White, or practically white, practically odorless, crystalline powder. Freely soluble in sodium hydroxide solution, in *n*-butylamine, and in dimethylformamide; very slightly soluble in water; sparingly soluble in methanol; insoluble in ether, in chloroform, and in dilute mineral acids.

Hydrocodone Bitartrate: Fine, white crystals or a crystalline powder. Is affected by light. Soluble in water; slightly soluble in alcohol; insoluble in ether and in chloroform.

Hydrocortisone: White to practically white, odorless, crystalline powder. Melts at about 215°, with decomposition. Sparingly soluble in acetone and in alcohol; slightly soluble in chloroform; very slightly soluble in water and in ether.

Hydrocortisone Acetate: White to practically white, odorless, crystalline powder. Melts at about 200°, with decomposition. Slightly soluble in alcohol and in chloroform; insoluble in water.

Hydrocortisone Butyrate: White to practically white, practically odorless, crystalline powder. Freely soluble in chloroform; soluble in methanol, in alcohol, and in acetone; slightly soluble in ether; practically insoluble in water.

Hydrocortisone Sodium Phosphate: White to light yellow, odorless or practically odorless, powder. Is exceedingly hygroscopic. Freely soluble in water; slightly soluble in alcohol; practically insoluble in chloroform, in dioxane, and in ether.

Hydrocortisone Sodium Succinate: White or nearly white, odorless, hygroscopic, amorphous solid. Very soluble in water and in alcohol; very slightly soluble in acetone; insoluble in chloroform.

Hydroflumethiazide: White to cream-colored, finely divided, odorless, crystalline powder. Freely soluble in acetone; soluble in alcohol; very slightly soluble in water.

Hydrogen Peroxide Concentrate: Clear, colorless liquid. Is acid to litmus. Slowly decomposes, and is affected by light.

Hydrogen Peroxide Solution: Clear, colorless liquid, odorless, or having an odor resembling that of ozone. Is acid to litmus and to the taste and produces a froth in the mouth. Rapidly decomposes when in contact with many oxidizing as well as reducing substances. When rapidly heated, it may decompose suddenly. Is affected by light. Specific gravity is about 1.01.

Hydromorphone Hydrochloride: Fine, white or practically white, odorless, crystalline powder. Is affected by light. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in ether.

Hydroquinone: Fine white needles. Darkens upon exposure to light and air. Freely soluble in water, in alcohol, and in ether.

Hydroxocobalamin: Dark red crystals or red crystalline powder. Is odorless, or has not more than a slight acetone odor. The anhydrous form is very hygroscopic. Sparingly soluble in water, in alcohol, and in methanol; practically insoluble in acetone, in ether, in chloroform, and in benzene.

Hydroxyamphetamine Hydrobromide: White, crystalline powder. Its solutions are slightly acid to litmus, having a pH of about 5. Freely soluble in water and in alcohol; slightly soluble in chloroform; practically insoluble in ether.

Hydroxychloroquine Sulfate: White or practically white, crystalline powder. Is odorless, and has a bitter taste. Its solutions have a pH of about 4.5. Exists in two forms, the usual form melting at about 240° and the other form melting at about 198°. Freely soluble in water; practically insoluble in alcohol, in chloroform, and in ether.

Hydroxyethyl Cellulose: White to light tan, practically odorless and tasteless, hygroscopic powder. Soluble in hot water and in cold water, giving a colloidal solution; practically insoluble in alcohol and in most organic solvents. *NF category:* Suspending and/or viscosity-increasing agent.

Hydroxyprogesterone Caproate: White or creamy white, crystalline powder. Is odorless or has a slight odor. Soluble in ether; slightly soluble in benzene; insoluble in water.

Hydroxypropyl Betadex: White or almost white, amorphous or crystalline powder. Freely soluble in water and in propylene glycol. *NF category:* Sequestering agent.

Hydroxypropyl Cellulose: White to cream-colored, practically odorless and tasteless, granular solid or powder.

Is hygroscopic after drying. Soluble in cold water, in alcohol, in chloroform, and in propylene glycol, giving a colloidal solution; insoluble in hot water. *NF category:* Coating agent; suspending and/or viscosity-increasing agent.

Low-Substituted Hydroxypropyl Cellulose: White to yellowish-white, practically odorless and tasteless, fibrous or granular powder. Is hygroscopic. Practically insoluble in alcohol and in ether. Dissolves in a solution of sodium hydroxide (1 in 10), and produces a viscous solution. Swells in water, in sodium carbonate TS, and in 2 N hydrochloric acid. The pH of the suspension, obtained by shaking 1.0 g with 100 mL of water, is between 5.0 and 7.5. *NF category:* Tablet binder; tablet disintegrant.

Hydroxyurea: White to off-white powder. Is somewhat hygroscopic, decomposing in the presence of moisture. Melts at a temperature exceeding 133°, with decomposition. Freely soluble in water and in hot alcohol.

Hydroxyzine Hydrochloride: White, odorless powder. Melts at about 200°, with decomposition. Very soluble in water; soluble in chloroform; slightly soluble in acetone; practically insoluble in ether.

Hydroxyzine Pamoate: Light yellow, practically odorless powder. Freely soluble in dimethylformamide; practically insoluble in water and in methanol.

Hymetellose: A white, yellowish-white or grayish-white powder or granules. Hygroscopic after drying. Dissolves in cold water, giving a colloidal solution. Insoluble in hot water, in acetone, in alcohol, in ether, and in toluene.

Hyoscyamine: White, crystalline powder. Is affected by light. Its solutions are alkaline to litmus. Freely soluble in alcohol, in chloroform, and in dilute acids; sparingly soluble in ether; slightly soluble in water and in benzene.

Hyoscyamine Hydrobromide: White, odorless crystals or crystalline powder. The pH of a solution (1 in 20) is about 5.4. Is affected by light. Freely soluble in water, in alcohol, and in chloroform; very slightly soluble in ether.

Hyoscyamine Sulfate: White or almost white, crystalline powder or colorless needles. Is deliquescent and is affected by light. The pH of a solution (1 in 100) is about 5.3. Very soluble in water; freely soluble in alcohol; practically insoluble in ether. Melts at a temperature not less than 200°.

Hypophosphorous Acid: Colorless or slightly yellow, odorless liquid. Specific gravity is about 1.13. *NF category:* Antioxidant.

Hypromellose: White to slightly off-white, fibrous or granular powder. Swells in water and produces a clear to opalescent, viscous, colloidal mixture. Insoluble in dehydrated alcohol, in ether, and in chloroform. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; tablet binder.

Hypromellose 2208: White to slightly off-white, fibrous or granular powder. Swells in water and produces a clear to opalescent, viscous, colloidal mixture. Insoluble in dehydrated alcohol, in ether, and in chloroform. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; tablet binder.

Hypromellose 2906: White to slightly off-white, fibrous or granular powder. Swells in water and produces a clear to opalescent, viscous, colloidal mixture. Insoluble in dehydrated alcohol, in ether, and in chloroform. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; tablet binder.

Hypromellose 2910: White to slightly off-white, fibrous or granular powder. Swells in water and produces a clear to opalescent, viscous, colloidal mixture. Insoluble in dehydrated alcohol, in ether, and in chloroform. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; tablet binder.

Hypromellose Acetate Succinate: White to yellowish-white powder or pills. Odorless, or has a faint, acetic acid-like odor, and tasteless. Practically insoluble in water, in de-

hydrated alcohol, in xylene, and in hexane. On the addition of a mixture of dehydrated alcohol and dichloromethane (1:1) or acetone, a clear or turbid viscous liquid is produced. Dissolves in 1 N sodium hydroxide. Slightly hygroscopic. *NF category:* Coating agent; tablet binder.

Hypromellose Phthalate: White powder or granules. Is odorless and tasteless. Practically insoluble in water, in dehydrated alcohol, and in hexane. Produces a viscous solution in a mixture of methanol and dichloromethane (1:1), or in a mixture of dehydrated alcohol and acetone (1:1). Dissolves in 1 N sodium hydroxide. *NF category:* Coating agent.

Ibuprofen: White to off-white, crystalline powder, having a slight, characteristic odor. Very soluble in alcohol, in methanol, in acetone, and in chloroform; slightly soluble in ethyl acetate; practically insoluble in water.

Ichthammol: Reddish-brown to brownish-black, viscous fluid, having a strong, characteristic, empyreumatic odor. Miscible with water, with glycerin, and with fixed oils and fats. Partially soluble in alcohol and in ether.

Idarubicin Hydrochloride: Red-orange to red-brown powder. Soluble in methanol; slightly soluble in water; insoluble in acetone and in ethyl ether.

Idoxuridine: White, crystalline, practically odorless powder. Slightly soluble in water and in alcohol; practically insoluble in chloroform and in ether.

Ifosfamide: White, crystalline powder. Melts at about 40°. Very soluble in alcohol, in ethyl acetate, in isopropyl alcohol, in methanol, and in methylene chloride; freely soluble in water; very slightly soluble in hexanes.

Imidurea: White, odorless, tasteless powder. Soluble in water and in glycerin; sparingly soluble in propylene glycol; insoluble in most organic solvents.

Imipenem: White to tan-colored crystalline powder. Slightly soluble in water and in methanol.

Imipramine Hydrochloride: White to off-white, odorless or practically odorless, crystalline powder. Freely soluble in water and in alcohol; soluble in acetone; insoluble in ether and in benzene.

Inamrinone: Pale yellow to tan powder. It is odorless or has a faint odor. Slightly soluble in methanol; practically insoluble or insoluble in chloroform and in water.

Indapamide: White to off-white, crystalline powder. Melts between 167° and 170°. Soluble in methanol, in alcohol, in acetonitrile, in glacial acetic acid, and in ethyl acetate; very slightly soluble in ether and in chloroform; practically insoluble in water.

Indigotindisulfonate Sodium: Dusky, purplish-blue powder, or blue granules having a coppery luster. Is affected by light. Its solutions have a blue or bluish purple color. Slightly soluble in water and in alcohol; practically insoluble in most other organic solvents.

Indinavir Sulfate: White or almost white, hygroscopic powder. Freely soluble in water; soluble in methanol; practically insoluble in heptane.

Indocyanine Green: Olive-brown, dark green, blue-green, dark blue, or black powder. Is odorless or has a slight odor. Its solutions are deep emerald-green in color. The pH of a solution (1 in 200) is about 6. Its aqueous solutions are stable for about 8 hours. Soluble in water and in methanol; practically insoluble in most other organic solvents.

Indomethacin: Pale yellow to yellow-tan, crystalline powder, having not more than a slight odor. Is sensitive to light. Melts at about 162°. Exhibits polymorphism. Sparingly soluble in alcohol, in chloroform, and in ether; practically insoluble in water.

Influenza Virus Vaccine: Slightly turbid liquid or suspension, which may have a slight yellow or reddish tinge and may have an odor because of the preservative.

Inositol: White or almost white, crystalline powder. Very soluble in water; practically insoluble in alcohol absolute and in ether.

Insulin: White or practically white crystals. Soluble in solutions of dilute acids and alkalis.

Insulin Injection: The Injection containing, in each mL, not more than 100 USP Units is a clear, colorless or almost colorless liquid; the Injection containing, in each mL, 500 Units may be straw-colored. Contains between 0.1% and 0.25% (w/v) of either phenol or cresol. Contains between 1.4% and 1.8% (w/v) of glycerin.

Insulin Lispro: White or practically white crystals. Soluble in solutions of dilute acids and alkalis.

Isophane Insulin Suspension: White suspension of rod-shaped crystals, free from large aggregates of crystals following moderate agitation. Contains either (1) between 1.4% and 1.8% (w/v) of glycerin, between 0.15% and 0.17% (w/v) of metacresol, and between 0.06% and 0.07% (w/v) of phenol; or (2) between 1.4% and 1.8% (w/v) of glycerin and between 0.20% and 0.25% (w/v) of phenol. Contains between 0.15% and 0.25% (w/v) of dibasic sodium phosphate. When examined microscopically, the insoluble matter in the Suspension is crystalline, and contains not more than traces of amorphous material.

Insulin Zinc Suspension: Practically colorless suspension of a mixture of characteristic crystals predominantly between 10 and 40 μm in maximum dimension and many particles that have no uniform shape and do not exceed 2 μm in maximum dimension. Contains between 0.15% and 0.17% (w/v) of sodium acetate, between 0.65% and 0.75% (w/v) of sodium chloride, and between 0.09% and 0.11% (w/v) of methylparaben.

Extended Insulin Zinc Suspension: Practically colorless suspension of a mixture of characteristic crystals the maximum dimension of which is predominantly between 10 and 40 μm . Contains between 0.15% and 0.17% (w/v) of sodium acetate, between 0.65% and 0.75% (w/v) of sodium chloride, and between 0.09% and 0.11% (w/v) of methylparaben.

Prompt Insulin Zinc Suspension: Practically colorless suspension of particles that have no uniform shape and the maximum dimension of which does not exceed 2 μm . Contains between 0.15% and 0.17% (w/v) of sodium acetate, between 0.65% and 0.75% (w/v) of sodium chloride, and between 0.09% and 0.11% (w/v) of methylparaben.

Inulin: White, friable, chalk-like, amorphous, odorless, tasteless powder. Soluble in hot water; slightly soluble in cold water and in organic solvents.

Iodine: Heavy, grayish-black plates or granules, having a metallic luster and a characteristic odor. Freely soluble in carbon disulfide, in chloroform, in carbon tetrachloride, and in ether; soluble in alcohol and in solutions of iodides; sparingly soluble in glycerin; very slightly soluble in water.

Iodine Topical Solution: Transparent, reddish-brown liquid, having the odor of iodine.

Strong Iodine Solution: Transparent liquid having a deep brown color and having the odor of iodine.

Iodine Tincture: Transparent liquid having a reddish-brown color and the odor of iodine and of alcohol.

Sodium Iodide I 123 Capsules: Capsules may contain a small amount of solid or solids, or may appear empty.

Sodium Iodide I 123 Solution: Clear, colorless solution. Upon standing, both the Solution and the glass container may darken as a result of the effects of the radiation.

Iodinated I 125 Albumin Injection: Clear, colorless to slightly yellow solution. Upon standing, both the Albumin and the glass container may darken as a result of the effects of the radiation.

Iodinated I 131 Albumin Injection: Clear, colorless to slightly yellow solution. Upon standing, both the Albumin and the glass container may darken as a result of the effects of the radiation.

Iodinated I 131 Albumin Aggregated Injection: Dilute suspension of white to faintly yellow particles, which may

settle on standing. The glass container may darken on standing, as a result of the effects of the radiation.

Sodium Rose Bengal I 131 Injection: Clear, deep-red solution.

Iodohippurate Sodium I 131 Injection: Clear, colorless solution. Upon standing, both the Injection and the glass container may darken as a result of the effects of the radiation.

Sodium Iodide I 131 Capsules: May contain a small amount of solid or solids, or may appear empty.

Sodium Iodide I 131 Solution: Clear, colorless solution. Upon standing, both the Solution and the glass container may darken as a result of the effects of the radiation.

Iodipamide: White, practically odorless, crystalline powder. Slightly soluble in alcohol; very slightly soluble in water, in chloroform, and in ether.

Iodipamide Meglumine Injection: Clear, colorless to pale yellow, slightly viscous liquid.

Iodixanol: White to off-white, amorphous, odorless, hygroscopic powder. Freely soluble in water.

Iodoform: Lustrous greenish yellow powder, or lustrous crystals. It is slightly volatile even at ordinary temperatures, and distills slowly with steam. Freely soluble in ether and in chloroform; soluble in boiling alcohol; sparingly soluble in alcohol, in glycerin, and in olive oil; practically insoluble in water. Melts to a brown liquid at about 115°, and decomposes at a higher temperature, emitting vapors of iodine.

Iodoquinol: Light yellowish to tan, microcrystalline powder not readily wetted by water. Is odorless or has a faint odor; is stable in air. Melts with decomposition. Sparingly soluble in alcohol and in ether; practically insoluble in water.

Iohexol: White to off-white, hygroscopic, odorless powder. Very soluble in water and in methanol; practically insoluble or insoluble in ether and in chloroform.

Iohexol Injection: Clear, colorless to pale yellow liquid.

Iopamidol: Practically odorless, white to off-white powder. Very soluble in water; sparingly soluble in methanol; practically insoluble in alcohol and in chloroform.

Iopanoic Acid: Cream-colored powder. Is tasteless or practically so, and has a faint, characteristic odor. Is affected by light. Soluble in alcohol, in chloroform, and in ether, and in solutions of alkali hydroxides and carbonates; insoluble in water.

Iophendylate: Colorless to pale yellow, viscous liquid, the color darkening on long exposure to air. Is odorless or has a faintly ethereal odor. Freely soluble in alcohol, in benzene, in chloroform, and in ether; very slightly soluble in water.

Iophendylate Injection: Colorless to pale yellow, viscous liquid, the color darkening on long exposure to air. Is odorless or has a faintly ethereal odor. Freely soluble in alcohol, in benzene, in chloroform, and in ether; very slightly soluble in water.

Iopromide: White to slightly yellow powder. Freely soluble in water and in dimethyl sulfoxide; practically insoluble in alcohol, in acetone, and in ether.

Iothalamate Meglumine Injection: Clear, colorless to pale yellow, slightly viscous liquid.

Iothalamate Meglumine and Iothalamate Sodium Injection: Clear, colorless to pale yellow, slightly viscous liquid.

Iothalamate Sodium Injection: Clear, colorless to pale yellow, slightly viscous liquid.

Iothalamic Acid: White, odorless powder. Soluble in solutions of alkali hydroxides; slightly soluble in water and in alcohol.

Ioxilan: White to off-white, practically odorless powder. Soluble in water and in methanol.

Iloxilan Injection: Clear, colorless to pale yellow liquid.
Powdered Ipecac: Pale brown, weak yellow, or light olive-gray powder.

Ipodate Sodium: White to off-white, odorless, fine, crystalline powder. Freely soluble in water, in alcohol, and in methanol; very slightly soluble in chloroform.

Ipratropium Bromide: White to off-white, crystalline powder. Freely soluble in methanol; soluble in water; slightly soluble in alcohol.

Irbesartan: White to off-white, crystalline powder. Slightly soluble in alcohol and in methylene chloride; practically insoluble in water.

Irinotecan Hydrochloride: Pale yellow to yellow crystalline powder. Sparingly soluble in water and in alcohol; slightly soluble in most organic solvents.

Iron Dextran Injection: Dark brown, slightly viscous liquid.

Iron Sorbitex Injection: Clear liquid, having a dark brown color.

Isobutane: Colorless, flammable gas (boiling temperature is about -11°). Vapor pressure at 21° is about 2950 mm of mercury (31 psig). *NF category:* Aerosol propellant.

Isoetharine Inhalation Solution: Colorless or slightly yellow, slightly acid liquid, gradually turning dark on exposure to air and light.

Isoetharine Hydrochloride: White to off-white, odorless, crystalline solid. Melts between 196° and 208° , with decomposition. Soluble in water; sparingly soluble in alcohol; practically insoluble in ether.

Isoetharine Mesylate: White or practically white, odorless crystals having a salty, bitter taste. Freely soluble in water; soluble in alcohol; practically insoluble in acetone and in ether.

Isflurane: Clear, colorless, volatile liquid, having a slight odor. Boils at about 49° . Insoluble in water. Miscible with common organic solvents and with fats and oils.

Isflophate: Clear, colorless or faintly yellow liquid. Its vapor is extremely irritating to the eye and mucous membranes. Is decomposed by moisture, with the formation of hydrogen fluoride. Specific gravity is about 1.05. Soluble in alcohol and in vegetable oils; sparingly soluble in water.

Isoleucine: White, practically odorless crystals, having a slightly bitter taste. Soluble in water; slightly soluble in hot alcohol; insoluble in ether.

Isomethoprene Mucate: White, crystalline powder. Freely soluble in water; soluble in alcohol; practically insoluble in chloroform and in ether.

Isoniazid: Colorless or white crystals or white, crystalline powder. Is odorless and is slowly affected by exposure to air and light. Freely soluble in water; sparingly soluble in alcohol; slightly soluble in chloroform; very slightly soluble in ether.

Isoniazid Injection: Clear, colorless to faintly greenish-yellow liquid. Gradually darkens on exposure to air and light. Tends to crystallize at low temperatures.

Isoopropamide Iodide: White to pale yellow, crystalline powder, having a bitter taste. Freely soluble in chloroform and in alcohol; sparingly soluble in water; very slightly soluble in benzene and in ether.

Isopropyl Alcohol: Transparent, colorless, mobile, volatile liquid, having a characteristic odor and a slightly bitter taste. Is flammable. Miscible with water, with alcohol, with ether, and with chloroform. *NF category:* Solvent.

Azeotropic Isopropyl Alcohol: Transparent, colorless, mobile, volatile liquid, having a characteristic odor and a slightly bitter taste. Is flammable. Miscible with water, with alcohol, with ether, and with chloroform.

Isopropyl Myristate: Clear, practically colorless, oily liquid. Is practically odorless, and congeals at about 5° . Freely

soluble in 90% alcohol; insoluble in water, in glycerin, and in propylene glycol. Miscible with most organic solvents and with fixed oils. *NF category:* Vehicle (oleaginous).

Isopropyl Palmitate: Colorless, mobile liquid having a very slight odor. Soluble in acetone, in castor oil, in chloroform, in cottonseed oil, in ethyl acetate, in alcohol, and in mineral oil; insoluble in water, in glycerin, and in propylene glycol. *NF category:* Vehicle (oleaginous).

Isoproterenol Inhalation Solution: Colorless or practically colorless, slightly acid liquid, gradually turning dark on exposure to air and light.

Isoproterenol Hydrochloride: White to practically white, odorless, crystalline powder, having a slightly bitter taste. Gradually darkens on exposure to air and light. Its solutions become pink to brownish pink on standing exposed to air, doing so almost immediately when rendered alkaline. Its solution (1 in 100) has a pH of about 5. Freely soluble in water; sparingly soluble in alcohol and less soluble in dehydrated alcohol; insoluble in chloroform and in ether.

Isoproterenol Hydrochloride Injection: Colorless or practically colorless liquid, gradually turning dark on exposure to air and light.

Isoproterenol Sulfate: White to practically white, odorless, crystalline powder. It gradually darkens on exposure to air and light. Its solutions become pink to brownish pink on standing exposed to air, doing so almost immediately when rendered alkaline. A solution (1 in 100) has a pH of about 5. Freely soluble in water; very slightly soluble in alcohol, in benzene, and in ether.

Isosorbide Concentrate: Colorless to slightly yellow liquid. Soluble in water and in alcohol.

Diluted Isosorbide Dinitrate: Ivory-white, odorless powder. [NOTE—Undiluted isosorbide dinitrate occurs as white, crystalline rosettes.] Undiluted isosorbide dinitrate is very soluble in acetone; freely soluble in chloroform; sparingly soluble in alcohol; very slightly soluble in water.

Isotretinoin: Yellow crystals. Soluble in chloroform; sparingly soluble in alcohol, in isopropyl alcohol, and in polyethylene glycol 400; practically insoluble in water.

Isoxsuprine Hydrochloride: White, odorless, crystalline powder, having a bitter taste. Melts at about 200° , with decomposition. Sparingly soluble in alcohol; slightly soluble in water.

Iradipine: Yellow, fine crystalline powder.

Itraconazole: A white or almost white powder. Freely soluble in methylene chloride; sparingly soluble in tetrahydrofuran; very slightly soluble in alcohol; practically insoluble in water.

Ivermectin: White to yellowish-white, crystalline powder. Slightly hygroscopic. Freely soluble in methanol and in methylene chloride; soluble in acetone and in acetonitrile; practically insoluble in hexane and in water.

Juniper Tar: Dark brown, clear, thick liquid, having a tarry odor and a faintly aromatic, bitter taste. Sparingly soluble in solvent hexane; very slightly soluble in water. One volume dissolves in 9 volumes of alcohol. Dissolves in 3 volumes of ether, leaving only a slight, flocculent residue. Miscible with amyl alcohol, with chloroform, and with glacial acetic acid.

Kanamycin Sulfate: White, odorless, crystalline powder. Freely soluble in water; insoluble in acetone, in ethyl acetate, and in benzene.

Kaolin: Soft, white or yellowish-white powder or lumps. Has an earthy or clay-like taste and, when moistened with water, assumes a darker color and develops a marked clay-like odor. Insoluble in water, in cold dilute acids, and in solutions of alkali hydroxides. *NF category:* Tablet and/or capsule diluent.

Ketamine Hydrochloride: White, crystalline powder, having a slight, characteristic odor. Freely soluble in water

and in methanol; soluble in alcohol; sparingly soluble in chloroform.

Ketorolac Tromethamine: White to off-white, crystalline powder. Melts between 165° and 170°, with decomposition. Freely soluble in water and in methanol; slightly soluble in alcohol, in dehydrated alcohol, and in tetrahydrofuran; practically insoluble in acetone, in dichloromethane, in toluene, in ethyl acetate, in dioxane, in hexane, in butyl alcohol, and in acetonitrile.

Labetalol Hydrochloride: White to off-white powder. Melts at about 180°, with decomposition. Soluble in water and in alcohol; insoluble in ether and in chloroform.

Alpha-Lactalbumin: Free-flowing, slightly hygroscopic light cream-colored powder. Freely soluble in water; soluble in wide pH ranges; insoluble in methanol, in alcohol, in ether, and in acetone. *NF category:* Buffering agent; bulking agent for freeze-drying; coating agent; complexing agent; emulsifying and/or solubilizing agent; stiffening agent; suspending and/or viscosity-increasing agent; tablet binder; tablet and/or capsule diluent; vehicle.

Lactic Acid: Colorless or yellowish, practically odorless, syrupy liquid. Is hygroscopic. When it is concentrated by boiling, lactic acid lactate is formed. Specific gravity is about 1.20. Insoluble in chloroform. Miscible with water, with alcohol, and with ether. *NF category:* Buffering agent.

Lactitol: A white or light brown, odorless crystal. Has a mild, sweet taste, and no aftertaste. *NF category:* Flavors and perfumes; tablet and/or capsule diluent.

Lactobionic Acid: White or almost white, crystalline powder with a melting point of about 125° with decomposition. Freely soluble in water; slightly soluble in glacial acetic acid, in anhydrous ethanol, and in methanol. *NF category:* Antioxidant.

Anhydrous Lactose: White or almost white powder. Freely soluble in water; practically insoluble in alcohol. *NF category:* Tablet and/or capsule diluent.

Lactose Monohydrate: White, free-flowing powder. Freely but slowly soluble in water; practically insoluble in alcohol. *NF category:* Tablet and/or capsule diluent.

Lactulose Concentrate: Colorless to amber syrupy liquid, which may exhibit some precipitation and darkening upon standing. Miscible with water.

Lamivudine: White to off-white solid. Soluble in water. Melts at about 176°.

Lamotrigine: A white to pale cream-colored powder. Slightly soluble in 0.1 N hydrochloric acid, in acetone, in methanol, and in water.

Lanolin: Yellow, tenacious, unctuous mass, having a slight, characteristic odor. Freely soluble in ether and in chloroform; soluble in hot alcohol; sparingly soluble in cold alcohol; insoluble in water, but mixes without separation with about twice its weight of water. *NF category:* Ointment base.

Lanolin Alcohols: Hard, waxy, amber solid, having a characteristic odor. Freely soluble in chloroform, in ether, and in petroleum ether; slightly soluble in alcohol; insoluble in water. *NF category:* Emulsifying and/or solubilizing agent.

Lansoprazole: White to brownish-white powder. Freely soluble in dimethylformamide; practically insoluble in water. Melts at about 166°, with decomposition.

Lauroyl Polyoxylglycerides: Pale yellow, waxy liquids. Freely soluble in methylene chloride. Dispersible in hot water. *NF category:* Ointment base; solvent.

Lecithin: The consistency of both natural grades and refined grades of lecithin may vary from plastic to fluid, depending upon free fatty acid and oil content, and upon the presence or absence of other diluents. Its color varies from light yellow to brown, depending on the source, on crop variations, and on whether it is bleached or unbleached. It is odorless or has a characteristic, slight nut-like odor and a bland taste. Practically insoluble in water, but it readily

hydrates to form emulsions. The oil-free phosphatides are soluble in fatty acids, but are practically insoluble in fixed oils. When all phosphatide fractions are present, lecithin is sparingly soluble in alcohol and practically insoluble in acetone. *NF category:* Emulsifying and/or solubilizing agent.

Leflunomide: White to almost white powder. Freely soluble in methanol, in alcohol, in 2-propanol, in ethyl acetate, in acetone, and in acetonitrile; practically insoluble in water.

Letrozole: White to yellowish, crystalline powder. Freely soluble in dichloromethane; slightly soluble in alcohol; practically insoluble in water.

Leucine: White, practically odorless, tasteless crystals. Sparingly soluble in water; insoluble in ether.

Leucovorin Calcium: Yellowish-white or yellow, odorless powder. Very soluble in water; practically insoluble in alcohol.

Leucovorin Calcium Injection: Clear, yellowish solution.

Levamisole Hydrochloride: White or almost white, crystalline powder. Freely soluble in water; soluble in alcohol; slightly soluble in methylene chloride; practically insoluble in ether.

Levetiracetam: White to almost white powder. Very soluble in water; soluble in acetonitrile; practically insoluble in hexane.

Levmetamfetamine: Clear, practically colorless liquid.

Levobunolol Hydrochloride: White crystalline, odorless powder. Soluble in water and in methanol; slightly soluble in alcohol and in chloroform.

Levocarnitine: White crystals or crystalline powder. Hygroscopic. Freely soluble in water, and in hot alcohol; practically insoluble in acetone, in ether, and in benzene.

Levodopa: White to off-white, odorless, crystalline powder. In the presence of moisture, is rapidly oxidized by atmospheric oxygen and darkens. Freely soluble in 3 N hydrochloric acid; slightly soluble in water; insoluble in alcohol.

Levofloxacin: Light yellowish-white to yellow-white crystals or crystalline powder. Soluble in dimethylsulfoxide and in acetic acid; sparingly soluble in water, in acetone, and in methanol; practically insoluble in glycerin and in *n*-octanol.

Levonordefrin: White to buff-colored, odorless, crystalline solid. Melts at about 210°. Freely soluble in aqueous solutions of mineral acids; slightly soluble in acetone, in chloroform, in alcohol, and in ether; practically insoluble in water.

Levonorgestrel: White or practically white, odorless powder. Soluble in chloroform; slightly soluble in alcohol; practically insoluble in water.

Levorphanol Tartrate: Practically white, odorless, crystalline powder. Sparingly soluble in water; slightly soluble in alcohol; insoluble in chloroform and in ether. Melts, in a sealed tube, at about 110°, with decomposition.

Levothyroxine Sodium: Light yellow to buff-colored, odorless, tasteless, hygroscopic powder. Is stable in dry air but may assume a slight pink color upon exposure to light. The pH of a saturated solution is about 8.9. Soluble in solutions of alkali hydroxides and in hot solutions of alkali carbonates; slightly soluble in alcohol; very slightly soluble in water; insoluble in acetone, in chloroform, and in ether.

Lidocaine: White or slightly yellow, crystalline powder. Has a characteristic odor and is stable in air. Very soluble in alcohol and in chloroform; freely soluble in benzene and in ether; practically insoluble in water. Dissolves in oils.

Lidocaine Hydrochloride: White, odorless, crystalline powder, having a slightly bitter taste. Very soluble in water and in alcohol; soluble in chloroform; insoluble in ether.

Lime: Hard, white or grayish-white masses or granules, or white or grayish white powder. Is odorless. Slightly soluble in water; very slightly soluble in boiling water.

Lincomycin Hydrochloride: White or practically white, crystalline powder. Is odorless or has a faint odor. Is stable in the presence of air and light. Its solutions are acid and dextrorotatory. Freely soluble in water; soluble in dimethylformamide; very slightly soluble in acetone.

Lincomycin Hydrochloride Injection: Clear, colorless to slightly yellow solution, having a slight odor.

Lincomycin Hydrochloride Soluble Powder: White to off-white, or light tan free-flowing, fine powder.

Lindane: White, crystalline powder, having a slight, musty odor. Freely soluble in chloroform; soluble in dehydrated alcohol; sparingly soluble in ether; slightly soluble in ethylene glycol; practically insoluble in water.

Linoleoyl Polyoxylglycerides: Amber, oily liquids. May develop deposit after prolonged storage periods at 20°. Freely soluble in methylene chloride; practically insoluble but dispersible in water. *NF category:* Ointment base; solvent.

Liothyronine Sodium: Light tan, odorless, crystalline powder. Slightly soluble in alcohol; very slightly soluble in water; practically insoluble in most other organic solvents.

Lisinopril: White, crystalline powder. Melts at about 160°, with decomposition. Soluble in water; sparingly soluble in methanol; practically insoluble in alcohol, in acetone, in acetonitrile, and in chloroform.

Lithium Carbonate: White, granular, odorless powder. Sparingly soluble in water; very slightly soluble in alcohol. Dissolves, with effervescence, in dilute mineral acids.

Lithium Citrate: White, odorless, deliquescent powder or granules, having a cooling, faintly alkaline taste. Freely soluble in water; slightly soluble in alcohol.

Loperamide Hydrochloride: White to slightly yellow powder. Melts at about 225°, with some decomposition. Freely soluble in methanol and in chloroform; slightly soluble in water and in dilute acids; very slightly soluble in isopropyl alcohol.

Lopinavir: White powder. Freely soluble in methanol and alcohol; soluble in isopropanol; practically insoluble in water.

Loratadine: White to off-white powder. Freely soluble in acetone, in chloroform, in methanol, and in toluene; insoluble in water.

Lorazepam: White or practically white, practically odorless powder. Sparingly soluble in alcohol; slightly soluble in chloroform; insoluble in water.

Losartan Potassium: White to off-white powder. Freely soluble in water; sparingly soluble in isopropyl alcohol; slightly soluble in acetonitrile.

Lovastatin: White to off-white, crystalline powder. Freely soluble in chloroform; soluble in acetone, in acetonitrile, and in methanol; sparingly soluble in alcohol; practically insoluble in hexane; insoluble in water.

Loxapine Succinate: White to yellowish, crystalline powder. Is odorless.

Lutein: Red, crystalline powder. Soluble in ethanol, in ethyl acetate, and in methylene chloride; partially soluble in hexane.

Lysine Acetate: White, odorless crystals or crystalline powder, having an acid taste. Freely soluble in water.

Lysine Hydrochloride: White, odorless powder. Freely soluble in water.

Mafenide Acetate: White to pale yellow, crystalline powder. Freely soluble in water.

Magaldrate: White, odorless, crystalline powder. Soluble in dilute solutions of mineral acids; insoluble in water and in alcohol.

Milk of Magnesia: White, opaque, more or less viscous suspension from which varying proportions of water usually separate on standing. pH is about 10.

Magnesium Aluminometasilicate: White powder or granules having an amorphous structure. Very slightly soluble in acids and in alkalis; practically insoluble in water and in alcohol.

Magnesium Aluminosilicate: White powder or granules having an amorphous structure. Very slightly soluble in acids and in alkalis; practically insoluble in water and in alcohol.

Magnesium Aluminum Silicate: Odorless, tasteless, fine (micronized) powder, small cream to tan granules, or small flakes that are creamy when viewed on their flat surfaces and tan to brown when viewed on their edges. Insoluble in water and in alcohol. Swells when added to water or glycerin. *NF category:* Suspending and/or viscosity-increasing agent.

Magnesium Carbonate: Light, white, friable masses or bulky, white powder. Is odorless, and is stable in air. Practically insoluble in water to which, however, it imparts a slightly alkaline reaction; insoluble in alcohol, but is dissolved by dilute acids with effervescence.

Magnesium Chloride: Colorless, odorless, deliquescent flakes or crystals, which lose water when heated to 100° and lose hydrochloric acid when heated to 110°. Very soluble in water; freely soluble in alcohol.

Magnesium Citrate Oral Solution: Colorless to slightly yellow, clear, effervescent liquid, having a sweet, acidulous taste and a lemon flavor.

Magnesium Gluconate: Colorless crystals or white powder or granules. Is odorless and tasteless. Freely soluble in water; very slightly soluble in alcohol; insoluble in ether.

Magnesium Hydroxide: Bulky, white powder. Soluble in dilute acids; practically insoluble in water and in alcohol.

Magnesium Oxide: Very bulky, white powder or relatively dense, white powder or granulated powder. Soluble in dilute acids; practically insoluble in water; insoluble in alcohol.

Magnesium Phosphate: White, odorless, tasteless powder. Soluble in diluted mineral acids; practically insoluble in water.

Magnesium Salicylate: White, odorless, efflorescent, crystalline powder. Freely soluble in methanol; soluble in alcohol and in water; slightly soluble in ether.

Magnesium Silicate: Fine, white, odorless, tasteless powder, free from grittiness. Insoluble in water and in alcohol. Is readily decomposed by mineral acids. *NF category:* Glidant and/or anticaking agent.

Magnesium Stearate: Very fine, light, white powder, slippery to touch. Insoluble in water, in alcohol, and in ether. *NF category:* Tablet and/or capsule lubricant.

Magnesium Sulfate: Small, colorless crystals, usually needle-like, with a cooling, saline, bitter taste. It effloresces in warm, dry air. Very soluble in boiling water; freely soluble in water; freely (and slowly) soluble in glycerin; sparingly soluble in alcohol.

Magnesium Trisilicate: Fine, white, odorless, tasteless powder, free from grittiness. Insoluble in water and in alcohol. Is readily decomposed by mineral acids.

Malathion: Clear, colorless, or slightly yellowish liquid, having a characteristic odor. Congeals at about 2.9°. Slightly soluble in water. Miscible with alcohols, with esters, with ketones, with ethers, with aromatic and alkylated aromatic hydrocarbons, and with vegetable oils.

Maleic Acid: White, crystalline powder. Freely soluble in water and in alcohol; sparingly soluble in ether.

Malic Acid: White or practically white, crystalline powder or granules, having a strongly acid taste. Melts at about 130°. Very soluble in water; freely soluble in alcohol. *NF category:* Acidifying agent.

Maltitol: White, crystalline powder. Very soluble in water; practically insoluble in ethanol. *NF category:* Humectant; sweetening agent; tablet and/or capsule diluent.

Maltodextrin: White, hygroscopic powder or granules. Freely soluble or readily dispersible in water; slightly soluble to insoluble in anhydrous alcohol. *NF category:* Coating agent; suspending and/or viscosity-increasing agent; tablet binder; and/or capsule diluent.

Maltol: A white, crystalline powder having a characteristic caramel-butterscotch odor, suggestive of a fruity-strawberry aroma in dilute solution. One g dissolves in about 82 mL of water, in 21 mL of alcohol, in 80 mL of glycerin, and in 28 mL of propylene glycol. *NF category:* Flavors and perfumes.

Maltose: Maltose occurs in either the anhydrous state or as a monohydrate. It is a white, crystalline powder, odorless, and has a sweet taste. Very slightly soluble in ethanol; freely soluble in water; slightly soluble in methanol; practically insoluble in ether.

Mangafodipir Trisodium: Pale yellow crystals or crystalline powder. Freely soluble in water; sparingly soluble in methanol; slightly soluble in chloroform; very slightly soluble in alcohol and in acetone.

Manganese Chloride: Large, irregular, pink, odorless, translucent crystals. Soluble in water and in alcohol; insoluble in ether.

Manganese Chloride for Oral Solution: Off-white to tan-colored powder with a strawberry odor. Soluble in water.

Manganese Sulfate: Pale red, slightly efflorescent crystals, or purple, odorless powder. Soluble in water; insoluble in alcohol.

Mannitol: White, crystalline powder or free-flowing granules. Is odorless and has a sweet taste. Freely soluble in water; soluble in alkaline solutions; slightly soluble in pyridine; very slightly soluble in alcohol; practically insoluble in ether. *NF category:* Sweetening agent; tablet and/or capsule diluent; tonicity agent; bulking agent for freeze-drying.

Maprotiline Hydrochloride: Fine, white to off-white, crystalline powder. Is practically odorless. Freely soluble in methanol and in chloroform; slightly soluble in water; practically insoluble in isooctane.

Mazindol: White to off-white, crystalline powder, having not more than a faint odor. Slightly soluble in methanol and in chloroform; insoluble in water.

Measles Virus Vaccine Live: Solid having the characteristic appearance of substances dried from the frozen state. Undergoes loss of potency on exposure to sunlight. The Vaccine is to be constituted with a suitable diluent just prior to use.

Measles, Mumps, and Rubella Virus Vaccine Live: Solid having the characteristic appearance of substances dried from the frozen state. The Vaccine is to be constituted with a suitable diluent just prior to use. Constituted vaccine undergoes loss of potency on exposure to sunlight.

Measles and Rubella Virus Vaccine Live: Solid having the characteristic appearance of substances dried from the frozen state. The Vaccine is to be constituted with a suitable diluent just prior to use. Constituted vaccine undergoes loss of potency on exposure to sunlight.

Mebendazole: White to slightly yellow powder. Is almost odorless. Melts at about 290°. Freely soluble in formic acid; practically insoluble in water, in dilute solutions of mineral acids, in alcohol, in ether, and in chloroform.

Mechlorethamine Hydrochloride: White, crystalline powder. Is hygroscopic.

Meclizine Hydrochloride: White or slightly yellowish, crystalline powder. Has a slight odor and is tasteless. Slightly soluble in dilute acids and in alcohol; practically insoluble in water and in ether; freely soluble in chloroform, in pyridine, and in acid-alcohol-water mixtures.
